

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

+ *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.

+ *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.

+ *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.

+ *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter `http://books.google.com` durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

FORTHCOMING EVENTS.

Saturday, July 3.

Edinburgh Architectural Association, annual excursion. Dunblane and Doune.

Tuesday, July 6.

Architectural Association of Ireland, annual excursion, July 6 to July 10. Headquarters at the Fleece Hotel, Cirencester, Gloucestershire.

Archæological and Architectural Society of Northumberland and Durham, annual meeting, July 6 and 7. Headquarters at Nithsdale.

Monday, July 12.

British Archæological Association. Sixty-sixth annual congress, July 12 to July 17. Headquarters at the Royal Hotel, Norwich.

Wednesday, July 14.

Town-Planning and Housing Exhibition. An exhibition promoted by the Hampstead Garden Suburb Trust, Ltd., the Co-partnership Tenants, Ltd., and the Garden Suburb Development Co., Ltd., will be held at Hampstead Garden Suburb from July 14 to August 7.

THE VICTORIA AND ALBERT MUSEUM.*

A PARADISE for the architectural student, indeed for any art student whose conception of art extends beyond the painting of oil pictures. Such will be the Victoria and Albert Museum when the new buildings opened by the KING and QUEEN last Saturday have been completely furnished with the many art objects that have hitherto been huddled together so that adequate study was almost impossible, or worse still, hidden away out of sight waiting for an opportunity of display.

The buildings, designed by Sir ASTON WEBB, R.A., and added to the former South Kensington Museum, enclose this latter towards Cromwell Road and Exhibition Road, and hence present to the public view an appearance more worthy, architecturally, of the premier art museum of Great Britain than the heterogeneous collection of mean buildings and sheds that formerly served but the utilitarian purpose of housing the nation's art treasures.

The principal entrance in Cromwell Road opens into an entrance hall from which right and left are staircases to the galleries, four storeys in height, which occupy the frontages to Cromwell Road and Exhibition Road. On plan these gallery buildings follow the line of the roads on which they abut, so that the principal front, that to Cromwell Road, follows a circular curve in a series of straight sections approximately tangential to the curve.

At the rear of the Cromwell Road galleries are a series of halls, lofty and top lighted, named the West Hall, the Central Hall, and the East Hall; then behind these runs a long, wide corridor, and off this a series of courts—the Octagon Court, West Court, West Central Court, Central Court, East Central Court, East Court—and then the old architectural court now to be called the Square Court. Thus the new buildings are brought up to and join the older portion of the museum.

Relying upon the principle that the proper decoration of a museum is its contents, Sir ASTON WEBB has kept his interior very simple in treatment; only in the entrance hall and its adjacent stairs has he permitted himself any departure from economical severity.

The entrance hall is treated in Portland stone with characteristic Astonian detail, and the stairs are in marble. The restricted amount of architectural features in the halls and courts is executed in plaster. Despite the severity of treatment there are many fine effects of vista, particularly in the halls and stairs, and it is in this direction rather than in elaborate detail that the skill of the designer has been shown. In the use of the detail that has been adopted Sir ASTON WEBB has created interest by a variation of theme. Thus, in the Octagon Court we have Corinthian columns of a somewhat French type, in the West Central and East Central Courts we have Doric columns, and so on.

From the preliminary guide issued by the Board of Education we learn that the new buildings have a frontage of 720 feet to Cromwell Road and 275 feet to Exhibition Road; the total length of galleries in the new building is just one mile, and the top-lighted courts have a superficial area of nearly 1½ acres. The scheme of sculptured decoration on the front includes statues of thirty-two famous British artists and craftsmen, ten painters, six sculptors, six architects, and ten craftsmen. These statues have been executed by Messrs. S. BOYES, V. HILL, R. GOULDEN, J. A. STEVENSON, LYNN JENKINS, PAUL MONTFORD, S. W. BABB, G. BAYES, A. BROADBENT, W. S. FRITH, J. GAMBLE, E. G. GILLICK, A. H. HODGE, A. B. PEGRAM, J. W. ROLLINS, R. SHEPHERD, A. G. WALKER, and O. WHEATLEY. The figure of Fame on the lantern and the two in the buttresses below, representing Architecture and Sculpture, are by Professor LANTERI, of the Royal College of Art. The statue of Queen VICTORIA, with her supporters St. MICHAEL and St. GEORGE, the statue of the PRINCE CONSORT under the arch

* See Illustrations.

Digitized by Google

195248

and the figures of Knowledge and Inspiration on either side of the entrance, are by Mr. ALFRED DRURY, A.R.A. The spandrils over the arch representing Truth and Beauty are by Sir GEORGE FRAMPTON, R.A., while the statues of King EDWARD VII. and Queen ALEXANDRA are by Mr. GOSCOMBE JOHN, R.A. The general architectural carving in the front was done by Mr. W. S. FRITH.

The general contractors for the foundations were Messrs. LESLIE & Co., of Kensington; and for the superstructure Messrs. HOLLIDAY & GREENWOOD, of Brixton. The following sub-contractors were engaged upon various classes of work:—Marble-work, Messrs. BURKE & Co., Messrs. FARMER & BRINDLEY, Messrs. WALTON, GOODY & CRIPPS; Mosaic, Art Pavements and Decorations, Ltd.; metal-work, Messrs. HART, SON, PEARD & Co.; ornamental plaster-work, Mr. G. P. BANKART; Mack partitions, Messrs. J. A. KING & Co.; Cranham brick partitions, Messrs. J. H. SANKEY & SON; expanded metal, Messrs. A. & J. MAIN, Ltd.; heating, Atmospheric Steam Heating Co.; glazing, Messrs. W. E. RENDLE & Co.; paint, Messrs. R. GAY & Co.; distemper, The Silicate Paint Co. and The Rapidal Paint Co.

The arrangement of the collections in the museum has been carried out on the basis of materials in which the various works of art are executed, save that architecture and sculpture, in which the museum is rich in examples, form a separate department. Under this scheme a difficulty arises in the classification of structures of wood, which might frequently be properly included under the category of architecture. To get over this difficulty the principle has been adopted of assigning to the department of Architecture any structure in wood that can be described as external, and to the department of Woodwork such structures as are internal. The term sculpture is used in its widest sense, and includes what is often and perhaps more properly described as carving. The main groups of the collections are arranged in subdivisions under the categories of (*a*) historical, by date; (*b*) local, by country of manufacture.

Architecture and Sculpture occupy a considerable proportion of the floor area of the new buildings, the West and East Halls, the galleries on the lower and upper ground floors east of the main entrance, as well as the old Architectural, now the Square, Court being devoted to this department. Thus the very remarkable series of examples of most of the important schools of the Renaissance possessed by the museum will have an opportunity of being carefully and thoroughly studied. The long corridor that divides and connects the halls from the courts is devoted to a series of drawings, prints, and photographs of an architectural character, which though at present scarcely in a sufficiently complete condition for the purpose, is intended to be developed into an architectural index.

The department of Woodwork which, as we have already explained, includes architectural detail of internal character as well as furniture, occupies galleries on the lower and upper ground floors west of the main entrance, and extending along both Cromwell Road and Exhibition Road frontages, and to this department are also allotted the floor areas of the West Central, Central, East Central, and East Courts. These courts already to some extent, and still more so when completely furnished, will have a specially charming effect, as the wall space around them is devoted to the department of textiles, which in non-technical language means in this case tapestries. The pleasure of the ordinary visitor has apparently been considered in the arrangement of these courts, which, with their tapestried walls and costly old furniture disposed on the floor, will have rather the effect of palatial show apartments than places for serious study. Indeed, the student of textiles comes off rather badly, as this department is located in a lengthy series of comparatively narrow corridors on the first floor, as well as furnishing the walls of the spectacular courts. As a compensation the new department of Engraving, Illustration, and Design exhibits original designs for silks and printed cottons of the eighteenth century.

The woodwork galleries, perhaps by reason of their being more completely arranged at present than some other parts of the new building, are to our mind the most attractive and enthusing portion of the museum, as the halls are not as yet wholly occupied and what objects are placed in them are to a certain extent only in temporary locations.

The galleries on the upper ground floor next Cromwell Road frontage contain a portion of the collection chronologically arranged to illustrate as far as possible the development of Italian sculpture from the thirteenth to the seventeenth century, and include examples of the work of the PISANI, LORENZO GHIBERTI, DONATELLO, BENEDETTO DA MAIANO, the DELLA ROBBIA family, MICHEL ANGELO, GIOVANNI DA BOLOGNA, JACOPO SANSOVINO, and other artists of the early Italian Renaissance.

The East Hall is also mainly devoted to Italian architecture, including the chapel of Santa Chiara, removed bodily in 1860 from the suppressed convent of Santa Chiara in the Borgo San Spirito at Florence, probably built by CRONACA about 1493. There are, however, included in the East Hall some Spanish, Flemish and French works of art of fifteenth and sixteenth century date, including an interesting collection of French sixteenth century architecture presented to the museum in recent years by Mr. J. H. FITZHENRY.

In the West Hall are some interesting examples of English architectural work in wood and some Flemish and German work, but this hall can hardly yet be considered arranged in its final form.

Taken altogether the new Victoria and Albert Museum, whether as a piece of architectural design or as a place for the study of architecture, is a national work of which we have just reason to be proud.

NOTES AND COMMENTS.

IN the case of the Municipal Gallery of Modern Art in Dublin, the exertions of Mr. HUGH P. LANE in the establishment of the museum have been recognised by the honour of knighthood. Though this gallery is rather more devoted to pictures than architecture, one cannot but be gratified by the honour paid to any efforts at forwarding the interests of art in whatever direction these may have been exhibited.

THE Guild of Architects' Assistants is the result rather of the development of the practice of young architects of the present day of spending their whole life as assistants rather than as attempting to make an independent position as principals. In this development it will be welcomed by principals who have hitherto found it most difficult to obtain the services of the class of assistant represented in solicitors' offices by managing clerks. It has often been said that it is easy enough to get any number of assistants who are worth thirty shillings a week, but next to impossible to obtain those who are worth to their employers five pounds a week or more. If the new guild will direct their attention to the enrolment of a superior class of managing assistants, they will find that employers will be only too ready to give berths to this class and treat them fairly and generously as permanent members of their staff.

A NEW bridge over the Thames such as the proposed "St. Paul's Bridge" is undoubtedly an urgent necessity for the traffic requirements of London. We hope also that the Bridge House Estates Committee of the City Corporation, in addition to the practical benefit of the proposed new bridge, will take care that London is to have a beautiful bridge instead of another eyesore. The ability of the Corporation funds to provide this new bridge without expense to the ratepayers is another argument, if any were needed, for the existence unimpaired of the Corporation of the City of London, and by making the new bridge a work of art the City authorities would still further justify their existence and earn the gratitude of the citizens.

Digitized by Google

SOME time ago we warned our readers against the attempt by a person professing to require tenders under an assumed name, applications to submit such tenders to be accompanied by a substantial deposit. A Mr. ROBERT ANDERSON, described as an architect, has been committed for trial on a charge of obtaining money by false pretences, and obtaining credit by fraud for retaining deposits to the extent of nearly 200*l.* accompanying tenders for building schemes, which it was stated at the hearing before the magistrate were chimerical. It behoves, therefore, all contractors who are asked to deposit money with tenders to assure themselves of the *bona fides* of the persons inviting the tenders.

DR. EVANS has made some further interesting discoveries at Knossos in a stone sepulchral chamber with vaulted roof of apparently an early period, the "Third Middle Minoan," that is about the eighteenth century B.C. In the chamber, although previously rifled, some gold rings with engraved subjects were found. The remarkable character of the early civilisation revealed by the previous discoveries at Knossos is maintained by these latest finds.

FROM the case of ROBERTSON *v.* WILLMOTT, tried before Mr. Justice WARRINGTON, it is established that an architect is practising his profession although he may be acting as assistant to another architect, and not in independent practice. The defendant under the covenants of a deed of partnership was prohibited from practising as an architect within a radius of ten miles from Cardiff Town Hall, and as manager to another architect he, in the judgment of Mr. Justice WARRINGTON, infringed that prohibition. This is a point for the Guild of Architects' Assistants.

THE Surveyors' Institution have further elucidated the action of the present Finance Bill proposals for the taxation of land values by their supplementary report, showing how many grievous hardships will probably be inflicted upon holders of property if the proposals are carried. Those hardships must necessarily reflect on architecture, which for its opportunities is largely dependent on the ability and willingness of landholders to undertake or encourage building.

A FITTINGLY graceful touch was added to the opening ceremony of the Victoria and Albert Museum by H.M. the KING, in bestowing on the spot the honour of knighthood on Mr. CECIL SMITH, the Director of the Museum; and the part taken by Sir ASTON WEBB in bringing this national monument to completion is, we hear, to be recognised by the honour of a C.B. The museum is so essentially in great part a study-ground for architecture that it is only fitting that recognition in the shape of honours should be given to the men who have produced this fine work.

IT will be curious to see how the Select Committee of the House of Commons that is considering the provisions of Part V. of the London County Council (General Powers) Bill decide between the conflicting evidence of architects, given particularly with reference to the point whether internal construction should be included within the scope of the Bill or not. On the one hand in favour of this course were Mr. H. D. SEARLES-WOOD and Mr. EDWIN O. SACHS; on the other, against it, were Mr. EDWIN T. HALL and Mr. J. S. GIBSON, as representatives of the Royal Institute of British Architects, and Mr. W. DUNN, who is recognised as an expert in reinforced concrete construction. Perhaps the Committee will follow the course of Sheriff SYM at Perth, who evaded the difficulty of deciding between conflicting evidence of experts by the Scotch verdict of "Not proven," in a claim for damages for interference of right of support. "Not proven" is, in a civil action of course, a failure of the plaintiff to establish his case, and the weight of evidence, supported also by the representative of the Master Builders, Surveyors' Institution, the Institute of Civil Engineers, and the Institute of Mechanical Engineers is against the existing provisions of the Bill.

THE stringency of the Italian law relating to ancient monuments and works of art is so severe that it defeats its own object, and it is practically impossible to prevent evasion, so that one is not surprised to hear that columns and capitals from the Temple of Apollo at Metapontum have been appropriated as building material. The neglect of the Italian Government—or perhaps one should say their financial inability—to deal with all the investigations and explorations desirable for the complete elucidation of Italian archæology and art has resulted in the shelving of work in Magna Græcia, and hence no doubt such vandalism as has now been discovered. However, we understand that the Italian Government are about to take up the work in this part of Italy which they have, dog-in-the-manger-like, refused to allow other nations to undertake.

ARCHITECTURE: ITS TRUE PRINCIPLES.—XIII.

By R. OWEN ALLSOP.

CONTRAST.

THE law of contrast may be said to lie at the root of all architectural effect. Contrast may be of light and shade, of form or line, of kind or position, and other opposites. Sunlight and shadow, smooth and sharp, breadth and length, rough and smooth, are the base of all effects, and if the principle of gradation is also considered most of all art effect is traced to its roots. Without shadow light is not effective, without sunshine the shade is of no value. The expression of RUSKIN, "broad sunshine and starless shade," summarises the noblest attributes of architecture.

An excellent example is to be found in the Greek "egg-and-tongue" moulding. The main effect of this is attributable to the contrast between the rounded mass of the "egg" and the spiny sharpness of the "tongue." If we desired to make a sharp contrast to a sphere we could suggest nothing more opposite to its character than an arrow. The contrast to a circle would be a straight line—but the contrast is evidently one of line only. If we contrast forms of three dimensions, one of which is a spherical body, we require three dimensions in the other. A crude ornament on the egg-and-tongue principle would be a series of spheres alternating with arrows. The ovate form of an egg is more graceful than the sphere and has a varied gradation, hence is more interesting to the eye. The violence of the contrast of the arrow-like tongue and the egg is in the Greek ornament subdued by the addition of a yoke round the egg. The graduation may be described as by means of the circular form of the yoke and its sharp arris, forming a step from soft roundness to spiny sharpness; but for the purpose of illustrating contrast of form, the yoke may be ignored, the root of the ultimate effect being the contrasting round body and sharp body—the arrow head. From this moulding we may learn that sharp and spiny forms brought into conjunction with smooth and rounded surfaces form an agreeable contrast, and that generally in applying enrichment to that which is smooth, round, and graduated, we may best employ sharp forms. Each form improves and adds to the value of the other, just as green and red colours improve and enhance each other's value. The same principle may be applied to the setting out of mouldings; round hollows and beads give a soft graduated shadow suitable for contrast to the sharp arris.

Much the same kind of contrasting effect to that of the egg-and-tongue may be noticed in the eastern

Digitized by Google

composition of round dome and tall, thin, needle-like minarets. Here the roundness of the hemisphere adds value to the thin lance-like towers, or more properly, perhaps, one should say that the sharpness of the towers enhances the effect of the domes. Less obvious contrasts are the thin, sharp pinnacles of a cathedral to the long, broad nave roof—a contrast of horizontal to vertical, of large broad mass to small thin ones. All these are effects of contrast, and in similar compositions it is always well to inquire whether the intended contrasts are as effective as they can be made, should it be desired to gain the extreme effect of contrast. Thus in an ornament of the nature of an egg-and-tongue, an ugly ellipsoid and a blunt coarse arrow would fail by reason of insufficient contrast of form; by giving more roundness to the one and sharpness to the other the effect must necessarily be greatly enhanced.

What is a more effective contrast than the square abacus and round echinus of the Doric capital? Above we have uncompromising squareness—squareness of plan and of outline, sharpness of arris horizontally and at the angles, below is a circular plan and a most delicately curved outline. The contrast is one of round to square, sharp to smooth, plane to curve. An octagonal abacus would enfeeble the contrasting members, the octagon form approaching towards the circular. It is to be assumed that the effect of "rusticating" a column is in the same way referable to the contrast of the round shaft and the square rusticated block.

In perspective the round of the column contrasts with the angularity of the square block, the soft graduated shadow of the column contrasts with the regular shading of the plane sides of the block, and the shadow cast by the block adds interest to the eye. So much we suppose; but there is yet none found to suggest that the fashionable rusticating system would benefit the Parthenon even if the shafts of the temple had been unfluted.

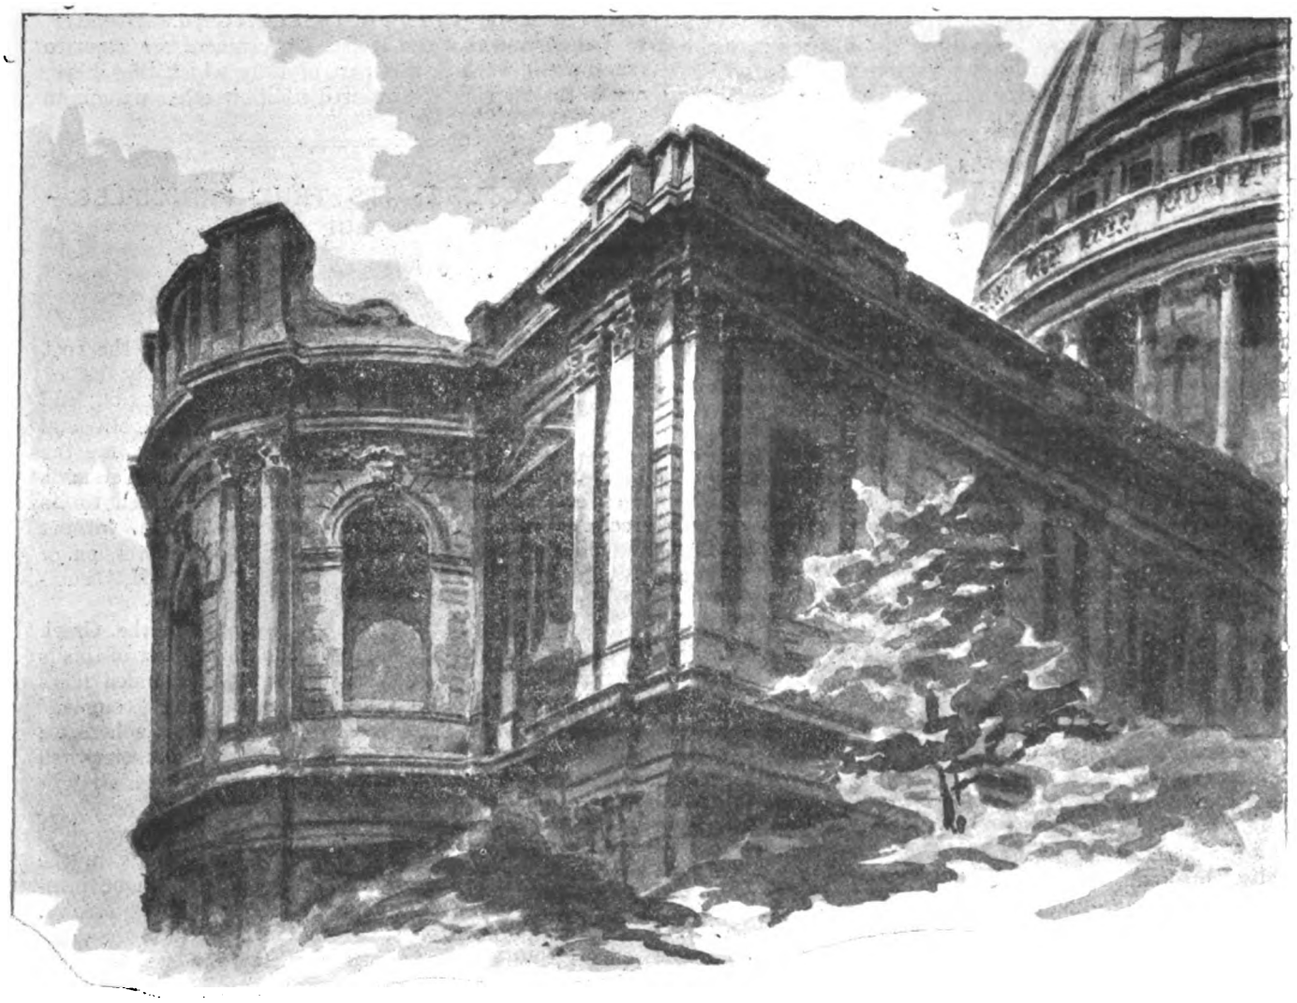

FIG. 33.—ST. PAUL'S.

We have considered first broad and apparent contrasts; others of this quality are the dark arch to the sunlit walling, the plain wall to the enriched portion—such as a diapering, polished to unpolished materials, flat surfaces to round, square masses to round, and to other variously shaped masses. Long horizontal masses contrast to vertical masses as a nave to a tower. Contrast of directions are found in crossing or abutting roofs. Contrasts of large to small are a row of small window lights over one of large dimensions as the lantern lights to lantern arches. Some light can always be thrown on the success of a composition by reflecting as to whether the contrast is bold and powerful, or weak and half-hearted (as in a feeble joke—a half-spoken truth). A notable contrast is the dark triforium opening and the brilliant clerestory. All these are plain contrasts and should be self-evident as such.

In every work of architecture no part of the composition—from sky-line to its most insignificant detail—is independent of the law of contrast for its effect. The thin vertical *flèche* contrasts with the long, broad roof. The light parts of the composition contrast with the shaded portions, as do the recesses with the main wall surfaces. The vertical columns contrast with the horizontal entablature. The lines of flutings contrast with the lines of bases. The main essential of a contrast is the mutual enhancement. A lack of contrast means loss of variety and tends to monotony. The wearisome repetition of parallel lines in the sharp perspective of our buildings would indicate an absence of appreciation

Digitized by Google

of the splendid effects to be obtained from contrasting varied form by varying plan. The magnificent effects of St. Paul's Cathedral are effects of contrast—the great square masses to rounded drum of dome. Let many of WREN's compositions be studied, and compared with much flat present architecture with its unvaried plan—the same square lines carried up storey after storey, with perhaps no break but that of the curved plans of the abacus of Ionic capitals. Compare the effect on sharp perspective of St. Clement Danes campanile with its studied variety in plan of the several stages. The upward gaze at a street façade presents generally one monotonous ruling of parallel lines. Observe how different a similar view of the fine Institute of Chartered Accountants with its elegantly varied plans and consequent play of form, line, and light and shade. The basis of these effects is the contrast of plan—square, round, octagonal, hexagonal, curved, and other variations and possibility of endless combinations. WREN made an especial study of contrasted planning, and the result is interesting—truly original composition of mass as distinct from monotonous elevational architecture.

(To be continued.)

THE COAL SMOKE ABATEMENT SOCIETY.

THE annual meeting of the Coal Smoke Abatement Society was held on Friday at the Royal United Service Institution, Whitehall, Sir W. B. Richmond, R.A., president, occupying the chair.

In the course of the annual report it is stated that the Society has now completed the tenth year of its existence. On the whole the members have every reason to congratulate themselves on the extent to which the Society has secured recognition and its objects have achieved success, for substantial progress has been made towards their ultimate goal—the purification of the atmosphere of the Metropolis and other large cities.

Much certainly remains to be done. But it is impossible to avoid recognising that the whole subject of smoke abatement has at last entered the region of practical administration. Ten years ago those who founded the Society met with indifference or derision, or were told that efforts to arouse interest in the work were doomed to fail. The law had been a dead letter in the case of nearly all the Metropolitan local authorities.

The Society therefore had a three-fold mission to perform. It had to stir public opinion to the necessity of steps being taken to abate the evil of smoke from the point of view of the health and comfort of the community; it had to demonstrate (and especially to manufacturers) that black smoke, so far from being a necessary accompaniment to prosperity was an avoidable waste of fuel; and it had to stimulate local authorities to a sense of the responsibilities which they owed to the public in protecting the atmosphere from unnecessary and unlawful pollution.

Public interest has been aroused, and the Rolls of the Patent Office show that the minds of many inventors are being devoted to the perfecting of fuels and appliances designed to mitigate or abolish smoke. Manufacturers are coming to recognize that they are the gainers when they secure perfect combustion of coal, and the plaint is now seldom advanced that it is impossible to avoid the issue of black smoke. Moreover, with a few regrettable exceptions, local authorities, led by the London County Council, take a commendable interest in the work of smoke abatement, and whereas the Society's reports and complaints were originally ignored, they are now generally welcomed as an assistance to effective action.

The Society has had much to do with the measure of success already achieved. By arousing interest; by forming and leading public opinion; by stimulating and fostering healthy competition amongst the makers of smoke abatement appliances and fuels; and by inaugurating a movement for training stokers it has been able to do much. Exhibitions have been organised, with the encouragement and co-operation of H.M. Commissioners of Works and Public Buildings elaborate tests of grates, gas fires and fuels have been carried out, men have been trained, and manufacturers and inventors have been aided. Besides all this, the Society has acted as a centre of advice and assistance for all needing information on the subject of smoke abatement. It is gratifying to the committee to know that in America and on the Continent various organisations have been formed, modelled on the lines of the Coal Smoke Abatement Society.

As an appendix to the report a short summary is added showing the work performed in 1900 and 1908. With few exceptions the smoke nuisances reported have greatly diminished in the areas of Metropolitan Borough Councils. Whereas in 1900 238 owners were reported to the borough councils for nuisances aggregating 15,672 minutes, last year only forty-seven of the same owners had to be reported, the nuisances then emitted only amounting to 4,611 minutes. The returns of sunshine issued by the Meteorological Council show that London is now receiving a much greater share of sunshine than was hitherto the case, and also that the improvement, if not rapid, is a steady one.

During last year 1,380 cases of smoke pollution were reported by the Society's inspector. In 1,323 instances the emission of black smoke was sufficiently constant and considerable to constitute a nuisance, and 1,274 complaints were forwarded by the Society to borough councils and other local authorities. In other and special cases representations were directly made by the Society to the offenders, in the majority of instances with satisfactory results. Indeed, a growing sympathy with the Society's work is manifesting itself amongst manufacturers themselves.

A number of summonses were issued and convictions obtained by local authorities acting upon the reports. As a rule, however, it was unnecessary to adopt this extreme course. For, as a result of the Society's efforts, the administration of the law has become so active and formidable that most of the offending firms took steps to abate the nuisances on receiving cautionary letters or preliminary statutory notices.

On numerous occasions the Society received requests from local authorities to permit its inspector to take observations jointly with their sanitary officers with the object of securing special evidence in regard to smoke nuisances.

With a very few exceptions Metropolitan Borough Councils welcome the co-operation of the Coal Smoke Abatement Society, and the provisions of the Public Health Acts are generally enforced with vigilance. There are, however, some exceptions, notably at Southwark. In 1900, the Society reported three firms within the area of the Southwark Borough Council whose chimneys emitted black smoke during the inspector's observations for a period of 362 minutes; in 1908 the same chimneys were observed by the inspector to emit black smoke for a period of 1,337 minutes, and moreover, four other firms were reported offenders. Last year fifty-two complaints were made to the Borough Council by the Society, nine by the London County Council, and thirty-seven nuisances reported by the Council's own officers. In no instances were proceedings taken, and the Society has pointed out to the London County Council that, in its view, the Southwark Borough Council fails to appreciate its duties to the public under the Public Health (London) Act, 1891.

A similar condition of affairs still exists in West Ham, where the Society has made 3,222 complaints in respect of a large number of firms, without a single prosecution having been initiated by the Corporation.

In the lower reaches of the Thames, too, and especially in the neighbourhood of Swanscombe and Northfleet, there are a number of stacks in connection with cement works and other factories which are notorious offenders in regard to the emission of smoke; but although the nuisances are patent to any observer, and in some cases are so bad as to be almost constant, the local authorities seem unwilling to move.

There has been an extension of the interest taken in the subject of smoke abatement in England and abroad. In the United States of America smoke abatement is receiving much attention, and reports of important investigations have been made public. These reports unanimously concur that it is quite practicable to burn bituminous fuel with proper apparatus or careful stoking without emitting black smoke and with economy to the manufacturers.

The attention of the committee was directed during the spring of 1908 to the North Metropolitan Electric Power Supply Bill, which proposed to enact that the company and its works should not be subject to indictment, action, or other proceedings for smoke or other nuisances. This was to be accomplished by a provision that the company should not be subject to section 81 of the schedule to the Electric Lighting (Clauses) Act, 1899.

The attention of the Committee of the House of Lords was drawn to the matter, and, at the instance of Lord Welby, an amendment was inserted to safeguard the public interests in the matter.

Digitized by Google

The Society has been frequently consulted with regard to smoke nuisances in the provinces, and it has been able to render considerable assistance by legal advice and by sending its inspector to prepare special reports, which have been laid before the local authorities, and in some instances have led to an abatement. The instances are unfortunately few; for without similar local societies to organise public opinion, and bring its pressure to bear on the authorities, effective action is very difficult to secure.

Sir W. B. Richmond, the chairman, in moving the adoption of the report, laid emphasis on the good work that had been achieved by the Society in its ten years of existence. When their operations were commenced the clause relating to smoke nuisance from factories, &c., was a dead letter, and public opinion was dormant. But now this had been changed and the Society instead of being called faddists or Utopian dreamers has become recognised as a practical body and assumed not merely a national but an international character. Some significant figures have been published by the Meteorological Office. From 1880 to 1892 the yearly average number of fogs was 69; from 1894 to 1899 the average was 56; in 1900 13 were recorded, and the yearly average since that date has been 31. Twenty per cent. of these fogs consist of smoke and nothing else, the remainder are gravely aggravated and increased in density by smoke. The sunshine in London last year also formed a record. But the Director of the Royal Meteorological Council has proved that in the City 83 per cent. of the burning power of the sun is lost in the winter months. It is of course impossible to be wholly rid of white fogs which are incidental to an insular position; but it is possible to be rid in a large measure of black fogs.

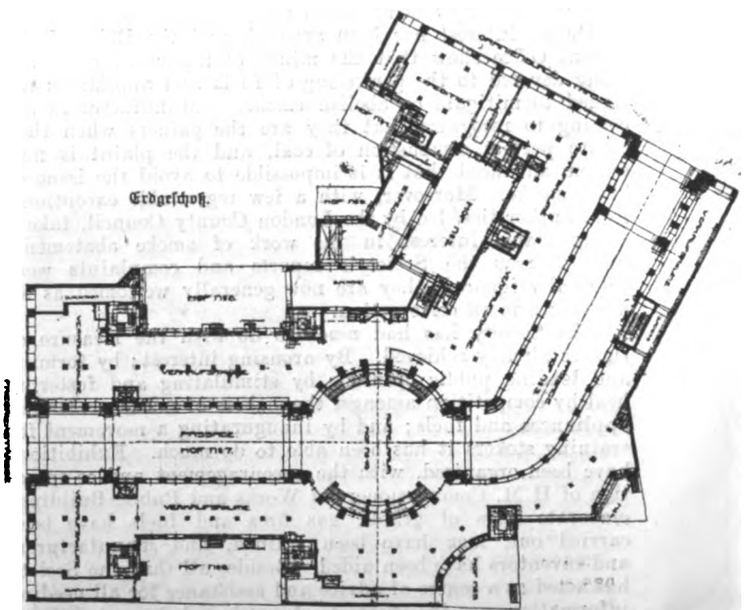
Sir William, after referring in detail to the encouragements and discouragements met with in the course of their work, then continued:—

The history of England is visibly enshrined in our great cathedrals, whose walls silently illustrate the great objects and deeds of our predecessors. From the kings who have ruled, the statesmen who have guided, to the craftsmen who created and wrought these great fabrics; the minds which conceived them, the master masons under whom they were created, and every trade and craft employed upon their embellishment, our cathedrals are trusts left to us to maintain and to preserve from decay, except from that which is in the nature of all things, the effect of time.

And to Londoners, even one might say to all English-speaking people, our abbey of St. Peter's in Westminster is the most beloved of all our edifices. No one needs reminding of its antiquity, its beauty, and of the countless treasures contained within its walls; of the kings and queens who lie buried there, and of the costly and magnificent tombs erected to the memory and delivered over as trusts for all time.

Do you wish to hand down to future generations as far as it is possible intact one of the chief objects of pride in our city? Of course you do. But in the multifarious demands made by modern materialism, the many poisons in the air wherever the swift, relentless wheels of commerce beat up the dust of destruction, the attractions of history and of art, of national sympathy with the past, the very foundation of all we now possess may take too limited a place in the modern mind.

It is a fact that Westminster Abbey has suffered from more rapid decay in the last hundred years, to give a broad limit, than occurred in all the years of its previous history. So serious has this decay become that an authority of the abbey approached the Coal Smoke Abatement Society, and a report furnished to the Society by Dr. John Owens, from which I am permitted to quote, is the result of the preliminary investigations. Personally I have many times visited the abbey, and can endorse all that the report states, though I have no pretensions to more than a very superficial knowledge of even the simpler departments of chemistry. I am able only to give you some of the chief points embodied in it. The Society hopes to carry the investigations much further by means of a special committee of distinguished experts whose report will be set before you in due course.



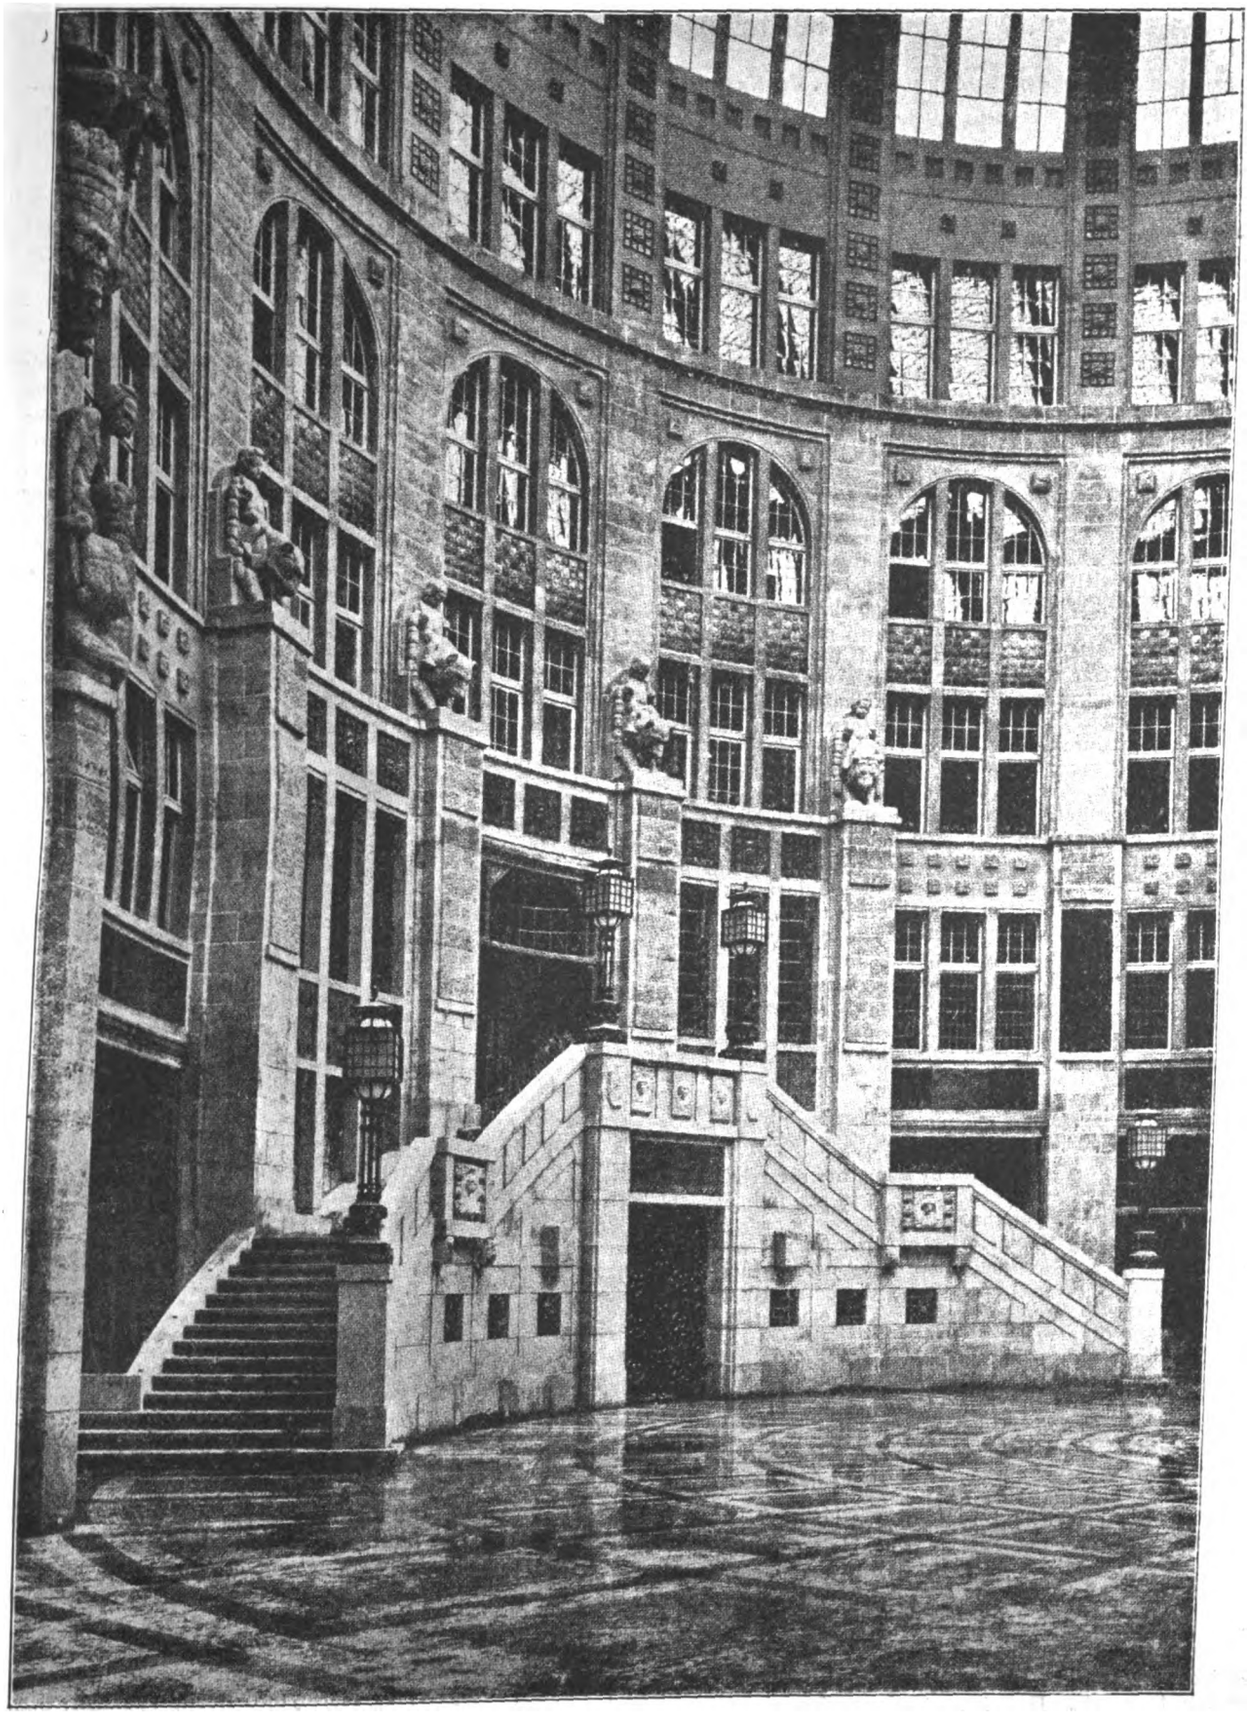
Repairs executed only from twenty to twenty-five years ago are decayed more or less. Those of the south transept and parapet are badly decayed. Work executed only fourteen years ago is in a bad state, and that done in 1701 shows signs of being reduced to a friable mass to a considerable depth below the surface. That this decay is the result of acids deposited by smoke and otherwise there can be no doubt whatever.

The chief cause of the destruction of the stone work has been shown to be the presence in the air of sulphur acids; the stone is converted into sulphate of lime; in the process of its formation this disintegrates the stone by expansion. The connection between smoke and stone decay appears to be invisible gases emitted from the smoke particles. It is now known that soot particles, though in themselves injurious, act as absorbents for the sulphurous acid produced from the sulphur in burning coal. The soot therefore is a vehicle for destruction though not in itself a destroyer. Another connecting link between stone decay and smoke is fog, in which the solid matter of the smoke plays an important part.

The particles of a London fog may be regarded as little spheres of acidulated water collected round nuclei of solid matter and probably coated with a tarry or oily skin derived from smoke. In a smoke fog, that is, a fog which is not due to moisture, the amount of acids is enormously increased; it has been shown by analysis of the air of London that the presence of a black fog increases the amount of sulphur about six times. Dull days in moist fog gave an average of 0.04 per 100 cubic feet, a black fog 0.224. In Glasgow on the suggestion of Sir J. Ure Primrose the rate of smut-fall was measured, and it was calculated that 22 cwt. per acre fell during the year; according to Sir William Thiselton Dyer's experiments at Kew nearly 2 tons are deposited per acre. In London the amount must be much greater. The summary of Dr. Owen's masterly report is:—"The chief points in connection with the preservation of the abbey where the work of the Society might be of value appear to me to be as follows:—(1) In reducing the amount of solid soot deposited on the stone work, and therefore the amount of sulphuric acid carried by it. (2) In reducing the frequency of black fogs, during which the corrosive properties of the air are greatly increased. (3) In encouraging the burning of fuels which contain little sulphur, and which at the same time produce no smoke; or the extended use of electricity." To the latter part of this sentence I append a note of my own, viz., no electrical generating station ought to be permitted to throw off any smoke at all. (4) "In encouraging the greatest possible care to reduce sulphur in coke, coalite, carbo, and other fuels."

The foregoing statements apply to all our cathedrals which happen to be surrounded by manufactories, to all buildings, to all works of art, of architecture, sculpture and painting, to all embroideries and fabrics. It is time that we took such a state of things into consideration and united together in a phalanx as far as possible to be rid of it, shutting our ears persistently to a constantly reiterated untruth, that smoke and successful commerce are necessary concomitants; we all know that they are not so.

We do not intend to hold our hands, we have not done fighting for pure air and light; we mean to go on, we mean to allow no plausible or superficial excuses of obviously interested persons to prevent our determination to get the country upon our side; even when we are richer we will go on with the same energy as we do now. We claim the right as citizens to criticise public bodies and we appeal to all English lovers of justice to lend us a hand; especially we ask the Press to give us its valuable help, even at a moment when the Budget and sky-flyers are in the ascendant, and terror of invasion is in the air.



GROUND PLAN OF ARCADE IN FRIEDRICHS-STRASSE, BERLIN.

The sky-flyers will get above the smoke and grumble that they cannot see the earth. And anyhow don't let us leave the clearing of the atmosphere to another great nation, great because it takes account of small things as well as big, an industrious and active nation, our near relatives in race.

We can do it if we will to, and keep before us that each one of us has a right to every ray of the sunlight obtainable, for reasons of health, happiness, vigour, out-of-door life, for the poor almost more than for the rich, for nature's and for art's sake.

FIREPROOF PAINTS.

AT the last meeting of the Paint and Varnish Society at Painters' Hall, Little Trinity Lane, E.C., Mons. Ch. Coffignier read a paper dealing with "Fireproof Paints." In the course of his remarks he said all the fireproof paints known up to the present day owe their particular properties to the presence of ammoniacal salts, and their fireproofing action is due to the liberation of ammonia on heating.

We are indebted to Mons. J. A. Martin for the following formulæ:—

Formulæ for Fireproofing Compositions (*Martin*).

1.	Sulphate of ammonia	8 parts.
	Carbonate of ammonia	2½ ,,
	Boric acid	3 ,,
	Borax	3 ,,
	Starch	2 ,,
	Water	1,000 ,,
2.	Ammonium hydrochloride	150 grs.
	Boric acid	50 ,,
	Animal glue	500 ,,
	Gelatine	15 ,,
	Water	1,000 ,,
3.	Ammonia hydrochloride	80 ,,
	Boric acid	30 ,,
	Borax	20 ,,
	Water	1,000 ,,
4.	Ammonia sulphide	80 ,,
	Boric acid	30 ,,
	Borax	20 ,,
	Water	1,000 ,,

By adding whitening to No. 2 formulæ the author professes to produce a fireproof coating, but with very indifferent success. Moreover, all these salts of ammonia are soluble, and it will readily be understood that their use is not conducive to the preparation of high-class paints.

It is the same as regards paints with an asbestos base. These paints settle very rapidly, and the difficulty experienced in putting them right again is a serious drawback. We must also add that they are very alkaline, and that is even a more serious drawback than the former. In fact, the coating they produce cannot be compared even with the commonest paint. Some time ago, in conjunction with M. Verine, I investigated the possibility of using magnesium ammonium phosphate, which is the only insoluble ammoniacal salt, and consequently may enter without ill effects into the composition of a paint. We found that this salt generated ammonia at a temperature of 150 degrees C., and that by simply incorporating it with ordinary paint, a coating is produced which is already less combustible than ordinary paint; but we obtained a much more decisive result by preparing a special varnish, having as a basis a metallic salt of linoleic acid, linoleate of lead for preference, dissolved in turpentine or benzine.

In order to obtain a fireproof paint it will be sufficient to grind the following mixture with this varnish:—

Powdered asbestos	75 ks.
Magnesium ammonium phosphate	75 ks.
Powdered white-lead	100 ks.

The white lead may be replaced by any other pigment. As far as the use of asbestos is concerned, it is not indispensable, but it reduces the cost of the paint.

I have made a whole series of experiments with these paints, ordinary paints and alkaline asbestic paints.

Here is a series of panels painted, some with ordinary paint, some with fireproof paint. You can easily see the characteristic differences.

On these boards being exposed for a couple of minutes to the flame of a Bunsen burner, with ordinary paint, the flame spreads very rapidly over the whole length of the panel (14 cm.). The board with fireproof paint is attacked only to a length of from three to four cm.; the paint becomes charred, but does not blaze; or if it does, it is only for a few seconds, and that very feebly.

This phenomenon may be explained by the fact that the action is local, and the wood unavoidably takes fire owing to the disintegration of the paint. But the flame does not spread; if the action of the heat is prolonged the spreading is in a great measure retarded; that is precisely what is required of a fireproof paint.

We have modified the above composition for the painting of ironwork and have prepared a special paint, which covers well in two coats. Here is an iron panel which has received three coats; you can see that the paint is slightly glossy and smooth; it lends itself, therefore, to decorative effect much better than ordinary paint.

The result obtained from the standpoint of incombustibility is very good indeed. You may hold this panel in the blue flame of a Bunsen burner, and it will show no tendency to flare, the paint merely blackens and adheres to the iron. Whereas, if I make the same experiment with this other panel, it only needs a few seconds to set up a general conflagration.

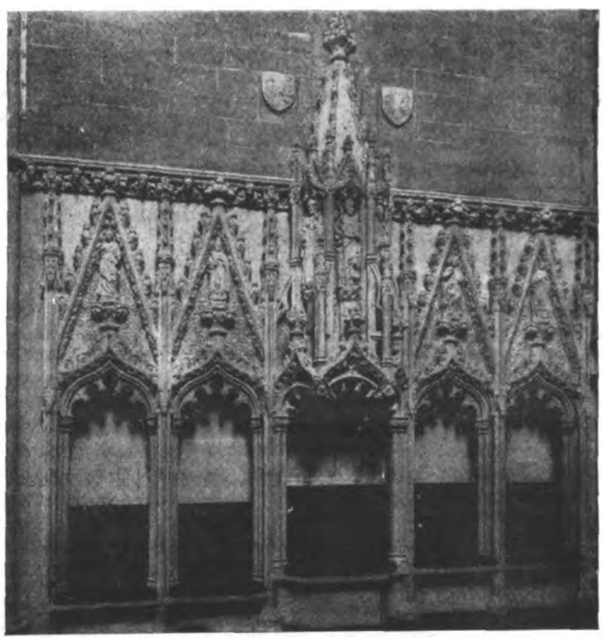
LIVING ARCHITECTS.—NO. 10. MR. H. T. HARE, F.R.I.B.A.



MR. H. T. HARE has already served the office of Vice-President, and has recently been elected Hon. Secretary of the Royal Institute of British Architects. He is one of our modern architects who has climbed to fame by the ladder of competitions.

NO. 11. MR. THOS. W. CUTLER, F.R.I.B.A.

MR. THOS. W. CUTLER has served on the Council of the Royal Institute of British Architects, and is well known for his domestic and semi-domestic work.

NEW REREDOS, PARISH CHURCH, ALL SAINTS, HOVE.

THE centre panel of this reredos is an historical representation of the Crucifixion. The figure of the SAVIOUR is one of great dignity; the expression is intended to denote pity for the sins and sorrows of men. There is a nimbus of angels, two of whom hold a crown. Around the Cross are the Virgin MARY, the two other MARIES, St. JOHN, the centurion, a soldier, and a Pharisee. On the north side of this panel are three types, one above another—viz., ISAAC with the wood, MOSES with the brazen serpent on a pole, and DAVID with a harp. On the south side there are shown the three prophets ISAIAH, JEREMIAH, and DANIEL. On the seven shields below are emblems of the Passion. Between the window lights are four angels under canopies. The wall spaces on either side of the altar are

divided into niches containing figures of St. STEPHEN, St. GEORGE, and St. ANDREW on the north side, with St. PATRICK, St. ALBAN, and St. DAVID on the south. On the north and south walls are the bishop's seat and the sedilia, the figures being of ecclesiastics who can be directly or indirectly connected with the See of Chichester. The design was made by the late J. L. PEARSON, R.A., the architect of the church. It has been worked out in detail by Mr. FRANK L. PEARSON, his son, and has been executed under his supervision by Mr. NATHANIEL HITCH, sculptor, 60 Harleyford Road, Vauxhall, S.E.

SIR JOHN MOORE CENTENARY.

AN event of the past week was the viewing of the clay model of the bust of Sir John Moore by Professor Bohanni. The committee are to be congratulated on the result of Professor Bohanni's efforts. The photograph from which our reproduction was made was taken by Mr. Max Judge. The bust is to be cast in bronze, and is to be embedded in a memorial shaft of silver-grey granite, to be erected on the

parade at Sandgate, close to the spot where Sir John Moore resided while he was forming the camp at Shorncliffe.

The centenary of the death of Sir John Moore and of the battle of Corunna was celebrated all over England, as well as in Spain, in January last. The Sandgate and Shorncliffe commemoration will take place during the present month.

GUILD OF ARCHITECTS' ASSISTANTS.

A WELL-ATTENDED meeting was held at Cardiff on June 18 in Messrs. Lanchester & Rickards' New Law Courts, to consider the formation of the Guild of Architects' Assistants, Mr. Lumsden presiding.

The Guild of Architects' Assistants was recently formed in London, the object being to remedy a state of affairs which has been growing more and more acute in recent years, and caused chiefly by the lack of co-ordination and unity between practising architects and their assistants. It is the outcome of a desire to protect the interests of properly qualified assistants from unfair competition, while securing for practising architects the advantages of knowing that they were only engaging qualified men, and at the same time uniting both parties in an endeavour to further the interests of the profession generally.

Mr. E. J. Dixon, A.R.I.B.A., London, founder of the Guild, delivered an address in favour of establishing a branch of the guild for South Wales and Monmouthshire. He pointed out the practical advantages of unity, saying that the sweet days of the Victorian era were passed when the principal took a real interest in his pupils. A different class of principal had arisen—a class of men in a hurry to get rich—and the result was that the position of the assistant had become extremely acute. He referred also to the architectural assistants turned out by the schools, colleges and even the university, without any attempt to regulate the supply.

It was these facts, these new phases of the question, which had given rise to the Guild. The assistants must combine for their own support and so be able to insure themselves against the many and various difficulties which arose in the course of their business. The benefit gained by mutual help would be of immense advantage to the rank and file of the profession. He drew attention to the fact that, for the great majority of the assistants, architecture was first and foremost their means of gaining a livelihood, and some steps ought to be taken to render that livelihood less precarious than was at present the case.

The Guild could act in a variety of ways for the benefit of its members. A principal had his remedy against an incapable or fractious assistant, but the assistant had no remedy in those cases where he was at the mercy of an unscrupulous employer. The guild would have to undertake cases of this kind, first by friendly remonstrance to the principal, and then by such other means as the nature of the case might suggest.

Then an employment bureau would be formed and an allowance made to those out of a berth. Endeavours would be made to organise a system of registration on a large scale so that by the central body or local branches having a list of vacancies, which could be supplied by sympathetic employers, they would be able to place many in situations who at present were unable to avail themselves of such advantages.

Statistics would have to be obtained in all centres as to the number of assistants and the percentage of unemployment before any definite unemployment scheme was adopted, but the tentative proposal was to pay a thirtieth of the salary to the funds, and receive a half of the salary when unemployed.

There was also the question of the graduation of salaries, which undoubtedly bristled with difficulties, yet he believed it was far from being impossible of solution. Much more could be done by the grading of assistants into their respective spheres as designers, draughtsmen, constructionalists, &c., and by co-operation of employers he had no doubt much could be accomplished in this way and so remedy a state of affairs under which some of the best men in the country were working for salaries no larger than paid to an artisan.

He also referred to a scheme of education, pointing out the anomalies of the present examination system.

Finally he invited all to do their best to bring the guild into active operation, and to see that it did not fail by reason of lack of energy. There was no body at present dealing exclusively with the interests of assistants, who were fast becoming a most important section of the profession; and it was for the guild to fill up this gap and unite all for their protection and advancement.

An animated discussion then took place in which several points of interest relating to the constitution of the branch and the scope of its work were satisfactorily answered by Mr. Dixon, and the following resolution was thereupon adopted:—

"That this representative meeting of architects' assistants, supported by several well-known local architects, recognising the urgent need of combination and union in order to further their professional interests, resolves that a branch of the Guild of Architects' Assistants for South Wales and Monmouthshire should be formed, with the headquarters in Cardiff, and that a committee be forthwith appointed for that purpose.

The provisional committee was then re-elected with power to co-opt others, Mr. S. Bowen Williams, of 110 Miskin Street, Cardiff, being appointed hon. secretary.

The Bolton Libraries Committee have decided that Messrs. Bradshaw & Gass be requested to prepare working drawings, specifications, &c., for the erection of the branch libraries at Astley Bridge and Great Lever, and Messrs. Henderson & Brown those for the building at Halliwell. Tenders are to be invited for the erection of the buildings.

EDINBURGH ARCHITECTURAL ASSOCIATION.

THE annual excursion of the Edinburgh Architectural Association will take place to-morrow, July 3, to Dunblane and Doune. On arrival at Dunblane by train the visitors will proceed to Dunblane Cathedral, where half an hour will be spent under the leadership of Mr. Hippolyte J. Blanc, R.S.A., F.R.I.B.A. The following notes have been prepared of this structure, which dates from the close of the thirteenth century, with some remains of an earlier foundation of David I. in the twelfth century; the main part of the edifice was founded by Bishop Clement about 1233. It consists of a nave of eight bays, with north and south aisles, an aisleless choir of six bays, an aisle-like attachment on one side of the choir, from which alone it is entered, a square tower of early formation oddly incorporated in a part of the south aisle of the nave. The tower bears some of the characteristics of the round towers of Abernethy and others, though, in this case, square. An interior arched recess shows some familiar details.

The two upper stages of the tower are of later date, and the parapet stage is probably of the sixteenth century. Judging from the details, the oldest part of the inner fabric is the long attached building on the north side of the choir, generally supposed, from the existence of certain appropriate features, to have been a lady chapel. An upper storey to this building is assumed to have been a scriptorium. The choir is of slightly later date. The window tracery in choir and the pinnacles of the buttresses are not the original. The crest of Bishop Chisholm, with date 1500, appears on one. The nave, 129 by 57 feet, including the aisles, bears very graceful and interesting detail. There is no triforium, but the clerestory has a passage-way in the thickness of the wall, which has double traceried perforations of elegant form. The west gable is most elegant, forms and details being exceedingly refined, while the doorway is deeply recessed with clustered shafts on in-goings. Three lancet-pointed windows fill nearly whole gable, upper part having vesica, with beautifully relieved decoration. The wall is built in two thicknesses, each perforated, as in the clerestory. The roof is of timber, in barrel-arch form. The cathedral is without transepts, contains many interesting features in doors and windows, also a few well-preserved oak-carved stalls and sculptured monuments. Nave recently roofed in and restored.

The next place to be visited will be Queen Victoria school, Dunblane (Messrs. John A. Campbell and A. D. Hislop, architects), where Mr. J. A. Campbell, F.R.I.B.A., will act as leader. The school, which also provides a residence for the boys, is, for the sake of economy, all planned under one roof, the pavilion type of plan originally proposed being abandoned. On the basement floor are the boiler-house, laundry, wash-house, drying chamber, &c. On the ground floor are the central hall, class-rooms, dining hall, serveries, kitchen and offices, cloak-rooms, lavatories, and day sanitary blocks. On the upper floors are the dormitories, and convenient to these are the ablution and bathrooms, night sanitary blocks (cut off from main building), reading room, boot-cleaning rooms, &c., student teachers' rooms, with private bathrooms and reading-room. The building is heated throughout by the Reck system. The problem of the building has been to provide a large amount of accommodation at a moderate cost. The houses in the ground are an adjutant's house and a residential block of twelve houses for non-commissioned officers and similar staff. The chapel is of a more architectural character in Late Decorated of a Scottish type. The building is harled with stone dressings from Auchenheath Quarry, and the roof is covered with Precelly slates of rustic green, mixed.

After luncheon at Stirling Arms Hotel, Dunblane, the visitors will drive to Doune Castle, the property of the Earl of Moray. Mr. Hippolyte J. Blanc will again act as leader.

Doune or Dun-a-hill castle is a good example of the evolution in the fifteenth century of the courtyard group of buildings from the simple square keep of the fourteenth century. Built by Murdoch, Duke of Albany, early in the fifteenth century. He was executed by decree of James I. in 1424, when the castle lapsed to the Crown, and was bestowed on the Queen of James IV., from whom it passed to the Stuart family, and remains the property of the Earl of Moray. The site possesses great defensive advantages. The north-east angle may be viewed as an enlarged keep, without internal communication with the other buildings, a usual arrangement in castles of the period in England and France. The area enclosed with buildings is about 155 feet by 143 feet. The main entrance is by an arched pend under the keep, protected by wood doors, iron gate and portcullis, the latter worked from an apartment immediately over. The ground floor contains guard room, prison, and a series of cellars. On the first floor of the keep is the great hall, 44 feet by 26 feet, and 24 feet 6 inches high, entrance to which is from outside stair only. Private rooms in the floors above are reached by a staircase from this hall. The first floor contains, in addition to the private hall, a large refectory or banqueting hall 67 feet by 25 feet, with kitchen and servery. There are many interesting features and details all in a good state of preservation. The castle was occupied by the rebels in 1745, and from that time up to about thirty years ago it remained ruinous and roofless. For preservation it was then re-roofed, and many details, so far as could be revealed, were renewed.

BRITISH CONSTITUTION ASSOCIATION.

THE Conference on the taxation of land values convened by the British Constitution Association and held at the Whitehall Rooms, Hotel Metropole, under the presidency of Lord Balfour, appointed a deputation to wait upon the Government, and the following letter was addressed to the Prime Minister:

"23 Charing Cross, June 19, 1909.

"The Right Hon. Herbert Henry Asquith, M.P., Prime Minister.

"Sir,—We write on behalf of a number of organisations connected with land whose representatives have met in conference to consider the land tax proposals of the Budget. The Conference unanimously agreed to make an appeal to his Majesty's Government to withdraw these proposals. In the opinion of the Conference they make an unjust and unintelligent distinction between property in land and other kinds of property. No such distinctions can, we submit, be drawn relevantly to taxation, and we deprecate financial proposals which by natural extension not more irrational than themselves might be made to justify the nationalisation of land. This proposed departure from principles which have hitherto been upheld by the Legislature of the United Kingdom would so seriously affect all classes of the community that the Conference appointed a deputation to wait upon his Majesty's Government in reference to the matter, and we trust that you will be good enough to appoint an early day for receiving the deputation. We are your obedient servants,

"BALFOUR OF BURIEIGH (*President*).
"HUGH CECIL (*Vice-President*).
"MARK H. JUDGE (*Hon. Secretary*)."

Among the organisations represented on the Conference are the following:—The Auctioneers' Institute, the Berks and Oxon Chamber of Agriculture, the Birkbeck Building Society, the British Constitution Association, the British Land Company, the Building Bye-Laws Reform Association, the Central Chamber of Agriculture, the Chatham Cottage Owners' Association, the Commercial Union Assurance Company, the Devon and Exeter Architectural Society, the Eagle Insurance Company, the Estate Agents' Institute, the Exeter Building Society, the Incorporated Association for the Protection of Property Owners, the Leeds Building Society, the Liverpool Building Societies (three), the London Friendly Institution, the London Master Builders' Association, the Surveyors' Institution, the Seabrook Estate Company (Limited), the Society of Architects, the Scottish Land and Property Federation, and the Western Suburban Building Society.

On June 25 the Hon. Secretary wrote to point out that the members of the deputation reside at such distant places as Edinburgh, Liverpool, and Exeter, and asked that, if possible, three days' notice of the time fixed for receiving the deputation may be given.

In reply the following letter has been sent:—

"10 Downing Street, Whitehall, S.W.,

"28*th June*, 1909.

"Dear Sir,—I am directed by the Prime Minister to acknowledge the receipt of your letter of the 25th instant, and in reply to your letter of 19th instant, in which you request him to receive a deputation from the British Constitution Association with reference to the Taxation of Land Values, I am to say that he very much regrets that his engagements are too numerous to permit him to do so.

"Mr. Asquith has, however, forwarded your letter to the Chancellor of the Exchequer, and he now understands that Mr. Lloyd George is willing to receive the proposed deputation. You will, no doubt, shortly receive a communication with reference to this matter from him.

"Yours faithfully,

"MARK STURGIS.

"Mark H. Judge, Esq., Hon. Sec. to the Conference."

Digitized by Google

The following Members of the Conference have undertaken the preparation of the Memorial which will be presented by the Deputation:—

Lord Balfour of Burleigh (President), Lord Hugh Cecil (Vice-President), Mr. Thomas Ambler, Lord Avebury, Mr. Edward Bond, Mr. James Boyton, Sir William Chance, Mr. Wilbraham N. Cooper, Lord Cottesloe, Earl of Cromer, Earl of Dalkeith, Sir George Darwin, Earl of Dysart, Mr. Edwin Evans, Mr. Howard Frank, Mr. S. Hutchinson Harris, Mr. Herbert Michell, Mr. Clarence F. Ravenscroft, Mr. C. F. Ryder, Mr. Alex. R. Stenning, Mr. J. St. Loe Strachey, Mr. Percy B. Tubbs, The Hon. Percy Wyndham, and Mr. Mark H. Judge (Honorary Secretary).

The adjourned meeting of the Conference to consider the reply of the Government to the Deputation will be held at the St. James's Hall, Great Portland Street, on Tuesday, July 20th, Lord Balfour of Burleigh in the Chair. Organisations connected with land not yet represented are invited to send four representatives to the adjourned meeting.

ELECTRIC LIGHTING AND FIRE RISKS.*

THE increasing number of fires caused by electric currents in buildings recorded in the fire brigade annual reports is my excuse for bringing up for discussion the subject of "Electric Lighting and Fire Risks" together with the question of the most efficient methods adopted of wiring buildings for electric lighting and power installations from the point of view of the fire brigade officer. Reviewing the origin of these causes we find the majority result from the fusion of gas pipes by a short circuit being formed from charged electric wire tubing, metal beams or columns and gas tubing. The principal cause of these defects is in my opinion due to the metallic conduit system.

I think it will be admitted that the metallic conduit has not fulfilled all the anticipations of its early promoters; as, notwithstanding the many improvements due to the introduction of screwed joints, metal junction boxes, &c., the metallic conduit has introduced to the electric light and power installations an element of danger which was unforeseen and unexpected, which may not be wholly confined to buildings in which it is installed, but which may be communicated by means of girders, columns, or water and other pipings to adjacent buildings.

It is impossible to avoid metallic contact with electric conduits, more especially in modern buildings where steel or iron and concrete form such large factors. A leakage on to iron girders or columns may travel through a building from top to bottom, or from one building to another before it gets to earth, or before it is picked up by a gas pipe, and thence conveyed to earth.

From information I have been able to gather, and from experience in my own city, many fires have been caused by such short circuiting of electric conduits on to gas pipes, or by leakage on to water pipes thence to gas, by girders on which gas pipes are in contact, by nails or staples bridging the current through joists or partitions, leakage of current from conduits on to damp walls thence on to gas pipes or brackets, the factors in each case being the conducting power of the metallic tubing.

It is difficult to suggest a remedy for the leakage of current on to the metallic conduits owing to the many breakdowns due principally to the conduit itself.

Amongst the defects which were not anticipated may be enumerated:—Those due to rough internal surfaces of the tube; barbed edges left by screwing dies; oil for lubricating the dies left in tubes; imperfectly insulated wire jointings; tubing not earthed or imperfectly earthed; vibration caused by moving heavy loads on floors; shorts on to small junction boxes due to imperfectly insulated joints being jammed into small space. The pulling of long lengths of wire through the tubing round bends, and often over sharp edges of tube, which damages the insulation. The tubing is frequently kept small for appearance sake, and the wire can only with difficulty be pulled through.

It was originally expected that the tubing would stand a slight short, and carry the current on to the earth, but experience has shown that a live tube is readily burned through when sufficiently close to any other conductor which will receive an arc. It was also anticipated that renewals and additions would be facilitated by the ready withdrawal of defective wires from the tubing and the substitution of others. We find, however, that owing to the condensation and rust set up inside the tubing the insulation becomes so saturated and swollen that the whole aperture is choked by the wire, necessitating the abandonment of both the defective wire and the tube and the running of an additional tube with the new wire on the surface.

Theoretically the metallic conduit should be the safer system; tubing faultlessly earthed is a perfect method of distributing electric current. By way of emphasising this fact, I may add that a properly earthed tube is so reliable to carry off a leakage of current as to admit of a gas pipe being run in close contact with it; but, when it is possible for the current to get an easier earth by the gas pipe, and the two are separated by sufficient space to admit of a short circuit taking place, or when the space between the two pipes is bridged by a nail or any other metal conductor, an arc is formed and the gas momentarily ignited.

The difficulty we have to consider is almost wholly confined to buildings in which both gas and electricity are installed, and to the danger arising from the adverse circumstances set up when the two are in conflict.

If it were possible to avoid the introduction of gas in the building or adjacent buildings, a leakage on to the tubing need cause the consumer no anxiety beyond the fact that the escaping current was passing through by his meter.

There seems to have been no really valid reason why wood casing as a conduit should have been almost entirely abandoned; perhaps it was in a large measure due to the very slovenly manner in which cheap and badly fitted casing was run, and to the assumption on the part of some people that all wood under any conditions is highly inflammable.

The introduction of the metallic conduit had the appearance of being a neat substitute for wood casing. Being more easily run out of sight, embedded in plaster and being non-inflammable, it promised to be a satisfactory substitute. My own experience has however been that not more than 2 per cent. of fires caused by defective electric circuits have been due to defects developed in wooden conduits.

An answer to this statement may be advanced that the small percentage of fires due to wood casing conduits is due to the equally small percentage of such installations in large centres. In advocating the use of wood casing as against metallic conduits, I am guided by the experience demonstrated by the fact that wooden conduits are perfect non-conductors, that the rubber insulation is better preserved in the wood than in the tubing; there is an entire absence of condensation in the conduit and a "short" from the conduit can only occur by the introduction of a conductor, foreign to the installation, such as nails, screws, &c., being driven through the casing on to the wires.

The trouble caused by wood absorbing water could be largely obviated by coating the casing with shellac varnish; the difficulty caused by the curling up of the edges of the capping would be overcome if the sides of the capping were screwed at the sides instead of in the centre only. A great advantage in favour of wood casing is that the wires are laid in and not pulled through, whereby the insulation is maintained intact, thereby removing one of the most frequent troubles met with in tube conduits. By removing the capping wires are easily get-at-able, facilitating renewals or extensions—an almost impossible operation with the tubes. Short circuiting of wires is avoided if the groove is of sufficient diameter to take the wire only; with neat hard wood casing the space required for conduit runs need not be necessarily thereby increased.

The capping should be checked and so fitted as to almost entirely exclude air spaces, thus retarding the spread of fire from burning insulation after the fuse has blown. When a "short" takes place between two wires in casing, and fires the insulation and the casing, the fire is easily located, whereas in the case of metallic conduits the fault which has caused the arcing on the gas pipe is generally very remote from the point of fusion.

Theoretically wood casing should not receive encouragement; apart from the very clumsy and often slovenly manner in which it was and is usually put on the surface of a well-decorated room, one would imagine that it would form a ready fire conductor. Experience has negatived this latter theory, and proved that from the danger point of view wood casing, though in itself inflammable, is safer than the metallic tubing which, though non-inflammable, forms a ready conductor of electricity and consequently of fire throughout buildings. There is no reason why wood casing should be offensive to the eye; it can be used with very artistic and decorative effect, the capping can be made to harmonise

* A paper read by Mr. Arthur Pordage, Firemaster of Edinburgh, on "Electric Lighting and Fire Risks" at the Fire Brigade Officers' Congress, Guildhall, Westminster, London, on June 16.

Digitized by Google

with the other wood fixtures and mouldings, whether of oak, mahogany or other decorative wood. It is a very good non-conductor and preserves the cable insulation as no other conduit system does.

The principal defects due to the wood conduit system are such as can almost always successfully be guarded against; but with this as with all other systems, workmanship forms a most important factor. The mere fact that a highly resinous wood is inflammable does not necessarily imply that all wood is similarly inflammable. A hard wood casing would take some time to get thoroughly well alight, the fire being easily located and above all restricted (the locality of the fault is not communicated by the conduit to several inaccessible parts of a building at the same time); it can be run under or on the side faces of iron or steel girders in such a manner as would spell disaster in the case of metallic conduits.

Wood casing has few supporters amongst electrical engineers and architects, but the increasing use of electricity for light and power, and with it the increasing number of fires caused thereby are sufficient to direct the attention of the advocates of electric lighting to consider the adoption of such methods of distributing the electric energy as will ensure that the best possible and safest means of supplying light to the community are not jeopardised by faulty systems.

Electric lighting and gas heating for domestic purposes are both now so absolutely indispensable to everyday life that the safest means of wiring buildings are essential for the proper safeguarding of life and property against methods which tend to menace alike the success of electric domestic supplies and the buildings in which they are installed.

Of the fire risks caused by electricity, I give the figures for London and Edinburgh during the past three years:—London, total fires caused by electricity, 294. Of this number 279 are returned as being due to defective electric circuits, overheating of electric lamps seven, and the remaining eight to minor causes. For Edinburgh, the total electric fires were forty-six; of this number thirty-five were due to shorting of tubing on to gas pipes, five were due to faulty flexible wires, six to overheating and minor causes.

The averages in other large towns are generally similar, proving that diminution of electric causes of fires, which is so desirable, could only be attained by the adoption of the really safe methods of distributing electric energy in buildings.

The opinions I have experienced may be contrary to the theory advanced by advocates of metallic conduits, but they are those gathered from practical experience and careful observation of facts demonstrated by fires which have been occasioned principally where electricity and gas have been in combination.

The success and popularity of electric installations depends upon the means adopted to distribute the current, which should not be the simplest or the cheapest, but the most effective; and architects might consider the provision in all buildings of channels for running electric mains and conduits. Electric supply has no stronger supporter than the fire service, which would view with alarm any retrograde step in the modern methods of lighting from electricity to the open flame burner.

BRUSSELS INTERNATIONAL EXHIBITION.

IN our issue of last week we were able to show why unusual importance attaches to the British Section of the International Exhibition to be held next year in Brussels, from May to October. Manufacturers have to consider, in regard to it, a totally new situation. Their very reasonable discontent with the character of international exhibitions in general, with the management of former British sections, and with the results of exhibiting, has brought this about. For the first time, what may properly be called a representative national exhibit is to be attempted; and this is being organised on the novel lines we indicated last week.

Exhibitors are no longer to be dependent on a voluntary committee, or left to instal their goods as best they can, or exposed to the risk of being obscurely placed, or required to defray the cost of a general scheme of decoration, or engaged in a speculation the cost of which they cannot ascertain beforehand. The section is in charge of a new department of the Board of Trade, acting in personal touch with them, and taking responsibility for these matters.

French and German exhibitors have long been assisted in systematic ways. Our own were at a disadvantage everywhere, and the result has been harmful to British prestige. But the new organisation undertakes to do more than is done for the exhibitors of any other country. In these circumstances Mr. U. F. Wintour, the British Commissioner-General, is approaching all the staple trades of the country with a view to secure at once that arrangements shall be made for an exhibit showing the scope and real importance of British manufactures.

The Royal Commission, which is presided over by the Prince of Wales, has its offices in Queen Anne's Chambers, Westminster. It is constituted wholly of well-known business men, and the occasion being unique, His Royal Highness is giving active help to the Commissioners.

A departmental inquiry, concluded two years ago, was the means of opening this fresh chapter in the history of international exhibitions. It was presided over by Sir Alfred Bateman. Taking the opinion of a large number of important manufacturers, the committee found a strong and growing prejudice against exhibitions on the old lines, and came to the conclusion that it was largely justified. But, as it would evidently be ruinous for Great Britain to abstain alone from a form of advertisement which is now established, they recommended effective means of meeting the grievances of British exhibitors.

The Exhibitions Department of the Board of Trade, which has been placed under the direction of Mr. Wintour, is the chief outcome. Instead of every exhibition being treated as a new problem of organisation—a problem more or less hastily and badly solved—this department exists as a permanent machinery for the care of British interests in such matters.

One of the most important facilities now offered is that the exhibitor will be in a position to calculate almost to a penny what his venture will cost.

The tariff of charges for space is as follows:—

	Per square foot. s. d.
Including the use of an isolated showcase, or part of a case having more than one frontage . . .	6 0
Including the use of a wall case	4 0
Including the use of a platform and ornamental façade without glass	4 0
Including the use of a platform only	2 6
On wall or screen	2 6
In the Machinery Hall, including the use of platform and hand railing where required	2 6

For motive power the charges are unusually low. The Royal Commission will defray half the charges made for it by the Belgian Administration, on all machinery driven to illustrate processes of manufacture. Thus exhibitors will pay:—

For steam (133 lb. pressure) ½ centime per kilogramme.
For gas 1*s.* 3*d.* per 1,000 feet.
Electricity (2 by 220 volts continuous) 1½*d.* per kilowatt hour.

Water will be supplied free for pumps or condensers. The charge for purer water in the Machinery Hall will be 1*s.* 10½*d.* per 1,000 gallons (50 lb. pressure), and in the Industrial Hall 1*s.* 8*d.* per 1,000 gallons for domestic, and 10*d.* for industrial purposes.

Not only will there be crane power, but the laying of foundations by Belgian contractors will be superintended by a competent engineer employed by the Royal Commission. With the above particulars, the railway and shipping freights, and the contractors' tender, an exhibitor of machinery can make his calculations with a degree of confidence not hitherto possible.

The Belgian State Railways, charging full rates on the outward journey, will return exhibits to their termini free of charge. The British railway companies will make a reduction of 50 per cent. on returned exhibits not sold, and travelling by the same route to the station from which they were sent out. Twelve shipping companies have also agreed to this 50 per cent. reduction.

It will be understood that all preparations begun so far in advance by the exhibitions department are part of the reform which has been described, and that a prompt response to the campaign now being carried on throughout the country is advisable in the interests of exhibitors, as well as of the general scheme.

Art and the "Liberal Arts" are well represented on the Royal Commission, of which the chairman is the Earl of Lytton, and the vice-chairman Sir Swire Smith. Representing pure art there are Sir Edward Poynter, President of the Royal Academy; Mr. Hippolyte Jean Blanc, Royal Scottish Academy; Sir Thomas Drew, President of the Royal Hibernian Academy; and Sir Isidore Spielmann, C.M.G. The Liberal Arts Commissioners are Sir Albert Spicer, Bart.,

Digitized by Google

M.P.; Mr. Emery Walker, ex-Master of the Art Workers' Guild; Captain Sir W. de Wiveleslie Abney, K.C.B., R.E., F.R.S., adviser to the Board of Education on matters connected with science, and ex-President of the Royal Photographic Society; Dr. R. Tetley Glazebrook, F.R.S., Director of the National Physical Laboratory.

The Liberal Arts committee include the following co-opted members of the Royal Commission:—Mr. W. Duddell, F.R.S., Dr. C. H. Lees, F.R.S., Major-General J. Waterhouse, Mr. R. Child Bayley, Mr. Robert S. Whipple, Mr. Alfred N. Disney, Mr. Edward H. Rayner, Mr. R. G. K. Lempfert, Mr. J. C. S. Mummery, A.R.I.B.A., Mr. Edward Unwin and Mr. Lewis Evans.

A special committee has been formed to cater for the interests of the trades concerned with buildings, decoration and furniture. Its co-opted members are:—Mr. A. B. Cowtan (Cowtan & Sons), Mr. J. B. Geake (Burnet & Co.), Mr. John H. Gill (Gill & Reigate), Mr. H. Percy E. Harding, Sir Horace Regnart, Mr. W. H. Romaine-Walker, Mr. S. J. Waring, Mr. E. White Wallis, and Mr. H. D. Searles-Wood, F.R.I.B.A. These gentlemen are associated with Mr. C. C. Allom, who was chairman of the decorative arts committee at the Franco-British Exhibition; Mr. L. C. Parkes, M.P., consulting sanitary adviser to the Office of Works; and Mr. G. Cartlich Moore, past President of the North Staffordshire Chamber of Commerce. These three are original commissioners.

SOCIETY OF ENGINEERS.

BY the courtesy of Messrs. Ellington & Woodall, MM.Inst.C.E., engineers to the London Hydraulic Power Company, a number of the members of the Society of Engineers were recently enabled to visit the company's new power station, which is in course of construction at Grosvenor Road, Westminster, about 300 yards west of Vauxhall Bridge.

When completed this building will be the largest of the company's pumping stations, and will replace the existing station at Millbank Street, which has been acquired by the London County Council for the Westminster Improvement. At the time of the visit the works were not in a sufficiently advanced state for the reception of the machinery, and interest centred principally in the ferro-concrete construction (Hennebique system), details of which follow.

Reservoir.—This is arranged in six compartments, each about 100 feet long, 38 feet wide, and 16 feet deep, the top water level being the level of the highest known tides. The vertical walls are all 12 inches thick at the bottom, tapering to 8 inches thick at the top, and spread out in the form of a T flange 3 feet wide, the flanges forming flat surfaces which are being utilised as gangways. The construction is so designed that the vertical walls are strong enough to resist the water pressure, when each or all the compartments are full, without external support of any kind.

Roadway.—The roadway is about 260 feet long, having an average width of 17 feet, and is carried along its length between vertical walls 17 feet apart. Underneath are the pipe subways. The ferro-concrete beams and floor forming the roadway are designed to carry a moving load of 16 tons on two axles, in addition to a super load of 1 cwt. per square foot.

Filter Floor.—This is carried by the walls of a building 89 feet long and 52 feet wide, having a central longitudinal beam supported by three columns, all the beams and columns being of ferro-concrete. The filter plant weighs 800 tons, which, with a super load of 150 lb. per square foot, brings the total weight to be carried by this floor to 1,100 tons. The three ferro-concrete columns are 22 inches square, and support other columns carrying the overhead water tank, the total load on each column being 310 tons.

The *coal store floor* is designed to carry a load of 7 cwt. per square foot, and covers the same area as the filter floor; the central portion is carried on the ground, and at each side the floor spans the coal conveyor trenches through which coal is carried to the boilers.

The *boiler blow-off tank* is a covered tank about 8 feet deep. The length is 36 feet, the width varies from 12 feet 6 inches at one end to 5 feet at the other end.

The *drains tank* is a small covered tank 9 feet long by 6 feet wide and 4 feet 6 inches deep.

These two tanks are below the level of the general drainage, and hydraulic ejectors will be used for pumping the water into the drains.

The buildings when completed will comprise engine and boiler houses, accumulator tower, chimney shaft, coal store, filter house, workshop, store room, men's room, and foreman's house, with water tanks over the boiler house and filter house. The settling reservoirs in the rear cover an area of 2,550 square yards, with a total capacity of about 2¼ million gallons. The wharf on which the coal handling apparatus, &c., will be erected, has a river frontage of 100 feet, subways under Grosvenor Road connecting the two sites. The station is designed to supply 200,000 gallons of power water per hour, at a pressure of 800 lb. per square inch. River water is to be conducted into the settling reservoirs at the rear through two lines of 20-inch pipes, laid at about half-tide level. The reservoirs can be emptied to the river at low tide through 14-inch drains. The water after settling is to be pumped from these reservoirs through the condensers into an overhead tank above the filter floor, is then filtered, and from the filters will flow into another tank, at a lower level, over the boiler house, from whence it will be conducted to the main engines with a gravity head, and pumped into the power mains.

There are at present about 165 miles of hydraulic power mains laid in London, and served by five central stations from two to three miles apart. The supply is over 20,000,000 gallons per week, with about 6,000 machines at work.

THE ELECTROLYTIC THEORY OF THE CORROSION OF IRON.*

THE Iron and Steel Institute has endorsed the economical importance of the general subject of the corrosion of iron by granting a Carnegie Research Scholarship for an investigation of this important problem. The holder of this scholarship, Dr. J. Newton Friend, in reporting the results of his work, dwelt entirely upon certain experiments which he had carried on and which he interpreted as a support of what has been called the carbonic acid theory of corrosion. At the same time the results of these experiments were considered totally to disprove the electrolytic theory of corrosion, and especially the work of the author of the present paper and that of his associates in support of this theory.

The author wishes to lay before the Institute as briefly as possible, firstly, the fundamental conceptions involved in the modern electrolytic theory of the corrosion of iron; secondly, to develop this theory from the facts now known, and to show that the older carbonic acid theory advocated by Dr. Friend can be, and is, included therein; and, thirdly, to point out some of the practical applications of this theory to the problem of corrosion as met with in engineering practice and daily life.

Ions and the Electrolytic Dissociation Theory.

In order to explain certain important and well-established facts, such, for example, as the electrical conductivity of salts dissolved in water, the abnormal lowering of the freezing point and the raising of the boiling point of water by the presence of dissolved salts, abnormal osmotic pressure, &c., there has been proposed and almost universally accepted what is known as the electrolytic dissociation theory. In accordance therewith, when a salt dissolves in water, a certain proportion of the dissolved molecules are regarded as dissociated or broken up by the water into component parts called ions. These ions act in the phenomena just mentioned, and in many others, just as whole molecules do. These parts of molecules may be made up of a single atom, or a group of atoms, but as individuals differ from real atoms in that they carry relatively large charges of electricity. This common salt-in-water solution furnishes two ions—the sodium ion carrying a positive electrical charge, and the chlorine iron carrying an equivalent negative charge. Water itself is somewhat dissociated into two ions oppositely charged—the positive hydrogen ion composed of one atom of hydrogen, and the negative hydroxyl ion composed of one atom each of oxygen and hydrogen.

Electrolytic Solution Pressure.

Every metal when placed in water, or under such conditions that a film of water may condense upon it, tends to dissolve in the water, or, in other words, to pass from its atomic or metallic condition into its ionic condition. This escaping tendency of the metals varies from that shown by sodium or potassium which is so great as to cause instant and rapid decomposition of the metal and water, to gold or platinum, where such tendency to dissolve is zero. Between these two extremes we find the other common metals,

* From a paper presented to the Iron and Steel Institute by William H. Walker, Boston, U.S.A.

Digitized by Google

including thereunder the element hydrogen, which may be considered as a metal. As the atom of metal passes into the water, it assumes a positive charge of electricity, leaving the metallic mass from which it separated charged negatively; this property or escaping tendency of the metal is termed its solution pressure. It is obvious, however, that this action can continue for only a short time; owing to the fact that the mass of metal and solution are of opposite polarity, the electrolytic tension becomes so great that no more atoms can escape to the ionic state, and the solvent action ceases. This condition was first described by Helmholtz, and called by him an electrolytic double layer. If now there be in the water ions of another metal which has a smaller solution pressure than the one under consideration, the action as above described will be reversed and the ion with the less solution pressure will pass back to the metallic state, plating out on the first metal and giving up its charge of electricity. At this point the first metal will be charged positively, and the solution in the immediate vicinity negative, and there will tend to be set up a second electrolytic double layer opposite in polarity to the first. The result is, a current of electricity flows from the metal to the solution at the point where the metal passes into solution, through the solution to the metal at the point where the ions of the second metal are plating out, and back through the first metal to the starting point again. The electrolytic double layers are thus destroyed, an electric current passes, and the solvent action of the water on the first metal continues.

This phenomenon and its relation to the corrosion of iron are clearly exemplified in the well-known Daniel or gravity cell.

In the case of pure iron in water a perfectly analogous condition is found to exist. Water itself is dissociated to a small but perfectly definite extent into its ions, hydrogen (H) and hydroxyl (OH). When a strip of pure iron comes into contact with water, it sends into the water iron atoms in the form of positively charged ions. Hydrogen as a metal has a much smaller solution pressure than iron, and hence an equivalent number of hydrogen ions plate out on the iron strip (leaving the free hydroxyl ions with their negative charges to balance the iron ions with their positive charges), and an electric current flows from the iron by means of the iron ions to the solution, and by means of the hydrogens from the solution back to the iron again, thus completing the circuit. But here comes an important break in the analogy of the film of copper in the Daniel cell. Deposited copper is a good conductor of the current, and offers no resistance to its flow from the solution to the iron on which it is attached. The reverse is true of the deposited hydrogen; here we have a high insulator—a film of gas which offers a great resistance to the flow of the current. Hence, although in the case of the iron strip in water all the conditions for continuous solution are present, owing to the resistance offered by the deposited hydrogen film (called polarisation) the action must cease.

Just as in the case of iron in a copper sulphate solution the rapidity of the action depended upon the number of copper ions present in the solution, so here the solution of the iron in the first instance depends upon the number of the hydrogen ions present. This number of hydrogen ions, or the concentration of these ions, is increased by the addition of any acid. So weak an acid as carbonic increases the number, but to a relatively small amount; while a strong acid, like hydrochloric or sulphuric, adds to the number to such an extent that the solvent action becomes violent, and the deposited hydrogen comes off as a stream of gas.

It is this aspect that Dr. Friend has ignored, and he has made some statements in this connection which, if taken seriously, can but prove a stumbling block to the progress of the study of corrosion. He gives experimental data, from which he concludes that, when pure iron is placed in water free from oxygen and carbonic acid, no iron is dissolved, because, under such circumstances, no iron was detected by him directly by the ordinary test for iron ions, namely, potassium sulphocyanate. But, on the other hand, he finds that, when the minute amount of carbonic acid which naturally adheres to the iron and to the sides of the containing vessel is present, iron will dissolve, and under these conditions can be later precipitated by oxygen as rust. Upon these observations he throws out the entire electrolytic theory of corrosion, and states, "We thus see that the electrolytic theory of corrosion is untenable."

Even though the entire accuracy of the experimental work just noted be granted, the fact remains that these data in no way contradict the electrolytic theory, but in reality they confirm it.

Dr. Friend did not detect the iron ions in the water in which his iron strip had stood, simply because his analytical methods were not sufficiently refined. As the author has shown, owing to the formation of the polarising film of hydrogen, the amount of iron in solution must of necessity be very small; but by using the excessively delicate method for determining dissolved iron devised by Stokes,* the amount of iron which has passed into solution can be accurately determined. As has been seen, the only effect which carbonic acid can have upon the solution of iron in water is that of any acid, namely, to increase the concentration of the hydrogen ions. This it surely does; and if Dr. Friend's observation be correct, which the author does not admit, namely, that this small amount of carbonic acid is necessary to the solution of the iron, this fact does not contradict the electrolytic theory, but can best be explained, and in truth can be explained only, by the use of the electrolytic theory.

It happens that there exists a very delicate test for the presence of the iron ion in the fact that potassium ferricyanide solution immediately forms therewith a bright blue colour; while, on the other hand, there is an organic substance known as phenolphthalien which becomes intensely red in the presence of hydroxyl ions. If, therefore, a piece of iron be placed in an aqueous solution containing potassium ferricyanide and phenolphthalien, which, to prevent convection currents, has been thickened with a little ordinary gelatine, there should be formed a bright blue colour at those points on the iron bar at which the iron is passing into solution, and a bright red colour on those portions on which the hydrogen is plating out, leaving in the solution at those places an equivalent number of hydroxyl ions.

(To be concluded.)

COMPETITION RESULTS.

IN the competition for a new library at Liscard, Cheshire, which was limited to architects practising in Lancashire and Cheshire, the Assessor, Mr. G. H. Willoughby, F.R.I.B.A., has awarded as follows:—

Premier design.—No. 34, by Messrs. R. B. MacColl and G. E. Tongo, Southport.

Bracketed second.—No. 8, by Mr. J. R. Earnshaw, Manchester; No. 30, by Messrs. Packer, Drewitt & Drewitt, Southport; No. 33, by Messrs. Appleyard & Quiggin, Liverpool; No. 41, by Messrs. Deacon & Horsburgh, Liverpool; No. 49, by Messrs. Sproat & Warwick, Liverpool.

Honourable mention.—No. 4, by Messrs. Cheers & Smith, Blackburn; No. 6, by Messrs. Potter & Langham, Manchester; No. 17, by Mr. Frank Rimmington, Liverpool; No. 35, by Messrs. Hobbs & Simon, Liverpool; No. 39, by Mr. C. T. Taylor, Oldham; No. 43, by Messrs. Briggs, Wolstenholme & Thornely, Liverpool.

The Libraries Committee at their meeting on Tuesday decided to proceed with the premier design, but this decision does not bind them to erect a building according to the selected or any other design.

The award of the assessor, Mr. H. T. Buckland, architect to the Birmingham education committee, in the competition for designs for the proposed school in Grove Street, Barnsley, is as follows:—1st, No. 28, 30*l.*; 2nd, No. 37, 20*l.*; 3rd, No. 21, 10*l.*; 4th, No. 31, no prize. On opening the sealed envelopes disclosing the identity of the competitors, it was found that the following were the names of those successful:—1st, Mr. E. W. Dyson, Barnsley; 2nd, Messrs. Clarke & Moscrop, Darlington; 3rd, Messrs. Holtom & Fox, Dewsbury; 4th, Mr. A. Brocklehurst, Manchester.

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *Architectural Review* (Boston) devotes the greater part of its illustrations to the Hanna Mausoleum, a costly structure after the fashion of a Greek Doric temple, with the exception that it is in plan Ionic tetrastyle amphiprostyle. It is a little curious to note these inconsistencies in an otherwise attempt to follow strict Greek precedent, for in the same number we have a view of the Entrance to the Field Memorial Library, Conn., Mass., which is distyle-in-antis with pure Ionic detail.

Dekorative Kunst has an appreciation of the work of Maximilian Dasio with particular reference to his designs for medals, but including also an account of his decorative design and drawing in other directions. There is also a

* *Journal of the American Chemical Society*, 1907, p. 451.

Digitized by Google

description of a modern brick house at Crefeld, of which Herr August Biebricher is the architect.

Deutsche Bauzeitung illustrates a remarkably successful design for the residence of Herr Adolf Dietler in Freiburg im Breisgau, of which Rudolf Schmid is the architect, and in which Greek detail is employed with quite refreshing modernism.

NOTES ON BOOKS.

"The Architecture of the Renaissance in Italy." By (the late) William J. Anderson. Fourth edition. (London: B. T. Batsford. 12*s*. 6*d*. net.)

THE fourth edition of this standard work has been edited by Mr. Arthur Stratton, and in the process has lost nothing of the value of the original, but is more excellent than ever. The mere fact that there are now seventy collotype and other plates and 110 illustrations in the text, as compared with the fifty-four collotype and other plates, and seventy-four smaller illustrations in the text of the first edition, is sufficient to show that much has been added. A comparison of the new additions shows that these have been wisely selected, and that their value is unquestionable, seeing that several are from measured drawings and sketches of Mr. Leslie Wilkinson. One may perhaps differ from the original author's views on some points, but cannot fail to recognise the high service he has rendered to the thoughtful student of the Renaissance architecture of Italy, a service that must render his work for a long while to come a classic in the literature of architecture.

"The Directory of Contractors and Public Works Annual, 1909." Edited by M. Sharpe. (London: *The Contractors' Chronicle*. 15*s*.)

This annual directory maintains its position of usefulness not only by the completeness and careful classification of contractors under the headings of the various classes of work they undertake, but by its lists of those with whom contractors have to deal in an official capacity, town clerks, municipal and district council engineers and surveyors, architects civil and naval, shipbuilders, the great public bodies of London. Further valuable information is contained in full reports of important legal cases concerning contractors, Bills in Parliament for the present Session, works in construction and works contemplated, so that this Directory becomes indispensable for all who are interested in contracts.

"Devon Church Antiquities." By John Stabb. (London: Simpkin, Marshall, Hamilton, Kent & Co., Ltd. 6*s*. net.)

This book is, as it were, a supplement to the same author's work on "Some Old Devon Churches," and gives details of many of the accessories that in the former volume were, for want of space, mentioned but not illustrated. It deals, therefore, more particularly with the distinctive features of the fitment of Devon churches, fonts, pulpits, screens and benches, the objects that preserve the evidences of the West-country skill in craftsmanship. There is an especial character about much of the carving in Devon, which, although to a slight extent shared by the work in Somerset, is nowhere to be found in England as in the West country, and proves that the men of Devon were ever hard hitters, whether they were carving oak or Spaniards. In the carving of the fifteenth century Devon craftsmen there is no hesitation, no tentative cutting away by gentle stages to the final form, but a bold and vigorous smashing into his material. The Devonian was, in fact, the Michel Angelo of wood carvers. It naturally results from this peculiar technique that the carved woodwork in Devon to some extent lacks delicacy and refinement, and is on occasion even coarse. And yet we do find sometimes that refined work was possible and produced in Devon, more often perhaps in stone than in wood; but such instances as Dunchideock and Harberton, for example, show skill in minutely delicate woodwork, equal to that of a German craftsman. Although there are examples remaining of painted decoration on the screens of Devon churches, they are not to be compared either in number or in execution with those of Norfolk and Suffolk. Carving in the West country, colour in East Anglia are the dominant excellences. Mr. Stabb has with a thoroughness that is born of love for his subject brought before us a characteristic collection of the beauties of Devonian craftsmanship of all periods from the eleventh to the eighteenth century that must attract visitors to his county, not the less that he is careful to tell us how we can get to many out-of-the-way churches containing practically unknown examples of artistic work.

"The Arts Connected with Building." Lectures on Craftsmanship and Design delivered at Carpenters' Hall, London Wall, for the Worshipful Company of Carpenters. By R. W. Schultz, C. F. A. Voysey, E. Guy Dawber, Laurence A. Turner, F. W. Troup, A. Romney Green, M. H. Baillie Scott, Chas. Spooner, and J. Starkie Gardner. Edited by T. Raffles Davison. (London: B. T. Batsford. 5*s*. net.)

The excellence of the lectures delivered each winter under the auspices of the Worshipful Company of Carpenters fully justifies their preservation in a more permanent and convenient form than the columns of a newspaper, and thus preserved it becomes possible to read again and again, till the lessons inculcated have been assimilated, such thoughtful and thought-inducing papers as that by Mr. Voysey on "Ideas in Things." We regret, however, to notice that the illustrations to the papers by Mr. Baillie Scott and Mr. Charles Spooner are wholly from their own designs. It not only savours of vanity to pursue such a course, but looks perilously like the blatant self-advertisement of a tradesman. It would have been excusable if all the lectures at Carpenters' Hall had dealt with woodwork; it is refreshing, therefore, to find that the art to be found in the craft of the plasterer, the leadworker, and the smith has also been included in the subjects on which lecturers have discoursed.

"Annals of Archæology and Anthropology," issued by the Institute of Archæology. Edited by J. L. Myres. Vol. I., Part 4. (Liverpool, at the University Press; London, Archibald Constable & Co. 2*s*. 6*d*.)

The contents of this part of Volume I. of the Annals contains a preliminary report on "Excavations at Sakje-Geuzi in North Syria," by John Garstang, and papers on "Early Civilisation in Northern Greece," by A. J. B. Wace, J. P. Droop, and M. S. Thompson. Professor Garstang's report includes as its most interesting matter, to ourselves at any rate, an account of the remarkable Hittite sculptures forming part of the architectural treatment of the portico of the Temple Palace that is still awaiting further excavation before the plan and nature of the building can be elucidated. Though these sculptures are obviously related to Assyrian art they nevertheless have local traits that stamp them as provincial work, and in the opinion of Professor Sayce are the work of the Hittites of North Syria, dating between the campaigns of Assur-nazir-pal in B.C. 880 and the conquests of Tiglath-Pileser III. about 730 B.C. The chief result of the excavations in Northern Greece seems to be that Almyro in Southern Thessaly can no longer be supposed to be the site of Itonos and the Temple of Athena Itonia. Further investigations are still needed to determine the relationship of the early civilisations of Northern Greece, though it would appear that there the neolithic age lasted till late Mycenean times.

Correspondence

[The Editor will not be responsible for the opinions expressed by Correspondents.]

Middlesbrough Library Competition.

SIR,—At the suggestion of certain architects the memorial and letter in reference to the above competition was sent to the competitions committee of the Institute, at the same time expressing the hope that they would take up the matter strongly, and to which they replied as follows:—

"The competitions committee have considered the objections to the assessor's award raised in your memorial to the Middlesbrough Council.

"It appears that the most serious objections to the award in your views are (1) the position of the lending library; (2) the area devoted to patents library, &c. The other objections do not appear to be of any great importance.

"With regard to the first the committee is of opinion that the clause in the instructions defining the position of the lending library is somewhat ambiguous, but it does not seem

Digitized by Google

to necessitate its actually abutting on the dwelling-houses. The suggestion is that it should be on that part of the block of land adjoining the dwelling-houses.

"Your second objection as to the area of the patents library seems to be due to a misapprehension of the schedule of accommodation given in the instructions. The 1,739 feet required includes corridors, lavatories, &c.

"An examination of the successful plan will show that the door from the news room to the entrance hall is a private pass door, and not for the use of the public.

"The Competitions Committee consider that when an assessor has been regularly appointed it would be well to bring any objection to the award before them in preference to approaching the promoters directly."

To which we replied disagreeing with their interpretation of the conditions, and laid the whole of the correspondence before the President of the R.I.B.A., at the same time sending a copy of same to the *Architect*, *British Architect*, *Builder*, *Building News* and *Builders' Journal*, all of whom published it in last week's issue, with the exception of the *Builder*, which had an article in support of the protest.

The President's reply, per the secretary R.I.B.A., was as follows:—

"The President of the Royal Institute of British Architects desires me to thank you for your letter. He has very carefully considered the terms of the protest which you have sent to him, together with the conditions and the successful design, and he has come to the conclusion that the decision arrived at by the Competitions Committee of the Royal Institute is a sound one."

We have replied as follows:—

"We have to acknowledge your letter of the 26th inst., but would point out that you appear to have misunderstood our intention in forwarding you the protest in question.

"This was sent to you, as head of the Institute, with the object of having the matter thoroughly investigated by the Council of the Royal Institute, and not by you personally (see clauses 3 and 4 in our letter), and we shall be obliged if you will be good enough to bring the matter before your Council at the earliest moment."—Yours faithfully,

HOSKINS & BROWN, Court Chambers, Darlington.
KITCHING & LEE, Houndgate Chambers, Darlington.
W. H. BOURNE, A.R.I.B.A., Houndgate Chambers, Darlington.

June 29, 1909.

Patriotism.

SIR,—I have to-day heard that the order for the granite for the premises of the New Automobile Club is likely to be sent to Norway; if so, Mr. Editor, may I suggest that this is monstrously unfair? Our Cornish granite is quite as good as this foreign, or any other foreign granite, quite as reasonable in price, can just as readily be supplied, and would give employment to our own countrymen. I want to enter a strong protest against the employment of foreign firms in preference to our own countrymen, and I do most sincerely hope that the architects will reconsider their decision (if it has been made), and give the Britisher a chance. As you are well aware, I am in no way connected with the granite industry, my interest is purely British, and whether I may be dubbed a tariff reformer or protectionist matters now't to —Yours truly, BRITISHER.

London: July 1, 1909.

Influence of Material.

SIR,—May I have the indulgence of a few lines after a renewed perusal of Mr. G. S. Aitken's paper in your issue of 18th inst.?

It is always a pity, when analysing admittedly good architecture, to be led away by fantastic imaginings. "Yonder phantom only flies, to lure thee to thy doom;" so wrote Goldsmith, and his lines would forcibly apply to the theory of the employment of arithmetical and geometrical proportion in the design of buildings. The "rule of three" referred to by Mr. Aitken is condemned out of his own mouth.

And his diagram of the Parthenon moves one to laughter. Does he really think that the Athenians—artists to the core—were dependent upon such a medley of triangles to obtain a well-proportioned façade? The theory of scientific, as contrasted with artistic, proportion would of course be worthy respectful consideration if Athenian buildings in general conformed (*accurately*, not loosely) to the tyrannous sway of angles and numbers. But there are insufficient examples extant; and if other Grecian buildings are analysed, other proportions are found, and yet the buildings are fine. To my mind, too, it is unsportsmanlike to juggle with base lines and apex lines for setting out triangulations, such as is customarily done by the school of scientific proportionists.

Another matter worthy Mr. Aitken's consideration is that the influence of material was a much more potent factor on architectural design than the influence of Nature; but I suppose he subscribes to Pope's false sentiment that:—

"All Nature is but Art unknown to thee;
All Chance, Direction that thou canst not see;
All Discord, Harmony not understood;
All partial Evil, Universal Good."

—Faithfully yours, PERCY L. MARKS.

Coal Smoke Nuisance.

SIR,—I have read with interest the article on the above subject appearing in your issue of the 18th inst. The use of gas stoves, both for heating and cooking, is undoubtedly having a marked effect upon the condition of the air in London, but we are still a long way behind Paris and other Continental cities. It will be found on investigation that the purity of the air in Paris is not entirely due to the use of gas stoves or electric radiators, but to the very large number of anthracite stoves which are so popular in that city, and it is not to be wondered at. In Paris the Welsh anthracite coal, on which an import tax has to be paid, costs the public there about 25 per cent. more than it does in London; yet it has been proved conclusively in that city that by means of anthracite stoves the rooms of a house can be much more economically heated than by gas, steam, hot water or electricity.

The initial cost of fixing an anthracite stove is not more than the initial cost of fixing a gas stove, and, no matter how cheap the gas may be produced by municipal authorities or gas companies, it will never be possible to heat a room 12 feet by 17 feet by 9 feet with a gas stove at a cost of 1*s.* 6*d.* per week, but it is possible to do so with an anthracite stove of the continuous burning type.

Half the householders in London imagine that anthracite is some patent fuel, and have no idea that coal-pit owners in this country are sending more than half what is mined from their pits to France and Germany in order that the houses in their great cities may be cheaply warmed and that the air may be purer than in London.—Yours faithfully, WM. CLARK.

23 Courthope Villas, Wimbledon:
June 24, 1909.

GENERAL.

Mr. Frederick Bligh Bond, F.R.I.B.A., director of the excavations at Glastonbury Abbey, has been elected diocesan architect for Bath and Wells. The other candidates were Mr. W. D. Caröe, architect to the Ecclesiastical Commissioners, and Mr. C. E. Ponting, one of the diocesan surveyors for Salisbury.

The Governors of the Watford Grammar School are putting up the plans of the new buildings in Cassiobury Park for competition among certain selected architects.

The Royal Society of Arts have awarded the Society's silver medal to the following readers of papers during the session, 1908-9:—Mr. Henry C. Brewer, "Gothic Art in Spain;" Mr. George Hubbard, "Dew-ponds;" Mr. Percy A. Wells, "English Furniture Design and Construction;" Mr. Arthur Anthony Macdonell (Boden Professor of Sanskrit, Oxford), "The Buddhist and Hindu Architecture of India;" Mr. Cecil L. Burns (Principal, Bombay School of Art), "The Functions of Schools of Art in India."

The Executive Committee of Selby Abbey restoration scheme met recently in the sacristry of the abbey. A lengthy discussion ensued with reference to certain work which it is absolutely necessary should be done to the abbey before the restoration could be completed in October, and it was decided to appeal for a sum of 1,000*l.* to carry on the necessary undertaking. The additional sum required is due to the fact that as the restoration work proceeded many defects had been revealed and weaknesses of the fabric observed that required speedy attention. It was announced that the total funds at present stood at 39,700*l.* 3*s.* 2*d.* The great east window of Selby Abbey, which was much damaged in the fire of three years ago, has now reached Selby from the restorers fully repaired, and is being placed in position by Messrs. Ward & Hughes, of London.

FORTHCOMING EVENTS.

Saturday, July 10.

Manchester Society of Architects. Visit to "Heathcote," Ilkley, Mr. E. L. Lutyens, architect. St. Margaret's Church, Mr. R. Norman Shaw, R.A., architect, and to Bolton Abbey.

Monday, July 12.

British Archæological Association. Sixty-sixth annual congress, July 12 to July 17. Headquarters at the Royal Hotel, Norwich.

Royal Society of Antiquaries of Ireland. Summer meeting for the province of Munster, July 12 to July 16. Headquarters at Clonmel.

Somersetshire Archæological Society. Sixty-first annual meeting. Headquarters at Wells.

Tuesday, July 13.

Manchester Society of Architects. Visit to Owens College. New Buildings—Students' Union, Messrs. Beaumont & Capper, architects; Engineering Laboratory, Professor Capper, architect; Gymnasium, Professor Capper and Mr. J. L. Grant, architect.

Wednesday, July 14.

Northern Architectural Association. Excursion to Selby and neighbourhood.

Town Planning and Housing Exhibition at the Hampstead Garden Suburb, July 14 to August 7.

Friday, July 16.

Architectural Association. Exhibition of work done in the School of Architecture and award of prizes. 3 P.M. to 6.30 P.M.

ARCHITECTURE AT THE ROYAL ACADEMY.

COMING now to the section of the exhibition devoted to buildings of a public and more or less municipal character we have in the "Design for New Post Office, Pretoria, S.A.," by Messrs. G. G. LEITH & W. LOUW, a striking design suggestive of a combination of old German and Modern Renaissance, piquancy is given to which by the joint use of gables and open loggia on the top storey. Messrs. SILCOCK & REAY show the perspective of their "First Premiated Design: Cornwall County Council Offices," but not their plan, which it was that won them the competition. Messrs. BAKER & MASEY'S design for "Rhodes Memorial, Cape Colony," is a Greek Doric Valhalla approached by a series of flights of steps with WATTS'S great statue of "Vital Energy" and the background of the Matoppo hills—altogether a very impressive composition.

"The New Wellesley Place Approach to Government House, Calcutta," by Mr. JAMES RANSOME, is a stately scenic arrangement of buildings symmetrically disposed on either side of the avenue, great depth of effect being obtained by the use of detached columns and arcades forming shady verandahs to the main walls of the buildings. The "New Wing, London Homœopathic Hospital," by Mr. EDWIN T. HALL, is quite of municipal character and with projecting pavilions and recessed centres turns an utilitarian type of building into a decent piece of architecture. "Glamorgan County Offices, Cardiff," by Mr. ROBERT ATKINSON, is a fine piece of detail design of Franco-Greek type beautifully drawn. Of similar excellence both in design and draughtsmanship, though of a different character, is the "Detail of Design for Glamorgan County Hall," by Messrs. S. B. RUSSELL & EDWIN COOPER. "Nos. 398 to 422 Oxford Street," by Mr. R. FRANK ATKINSON, illustrates SELFRIDGE'S Store.

Several of the competition designs for the new London County Hall are exhibited on the Academy walls, though it is now some little time since the competition was decided. The design by Mr. C. STANLEY PEACH is, as far as exterior goes, for no plan is shown, an excellent one, with a dome, and therefore too costly to compete with the selected design. Mr. WILLIAM HAYWOOD'S design is an example of dignified common sense. Mr. BERTRAM LISLE'S "Design for a Town Hall and Municipal Building" is student's work, but distinctly good. "A Design for Glamorgan County Offices," by Messrs. E. GARRATT & H. W. SIMISTER, is well composed, with a colonnade in the centre and free from extravagance. Mr. PAUL WATERHOUSE'S "Prudential Assurance Company Offices, Aberdeen," is a scholarly and refined design shown in an excellent perspective in Indian-ink wash. "Mission Hospital at Hebron, Palestine," by Messrs. CLAUDE KELLY & A. DICKIE, is an impressive composition to which a distinctive Eastern character has been imparted.

The design for "New Premises, London and County Bank, King's Road, Chelsea," by Mr. REGINALD T. BLOMFIELD, A.R.A., introduces an interesting variant on ordinary methods of design, this being virtually a stone building with red brick pilasters; the effect is, at any rate in the drawing, distinctly successful. The "Central Entrance, Hull Town Hall," by Messrs. S. B. RUSSELL & E. COOPER," is shown by a big coloured drawing, in which the detail is clear. It strikes us that the actual doorway appears small, and looks as if it were an accident in the design. Messrs. H. V. ASHLEY & WINTON NEWMAN show their design for "Birmingham Council House Extension" in a practical and workmanlike coloured elevation. Messrs. COLLCUTT & HAMP'S "Competition Design for Cardiff County Offices" is rather too pretty and not sufficiently dignified for its purpose or its position. "Proposed Street Bridge and Towers," by Mr. JAMES A. SWAN, looks like part of a design for the extension of the Birmingham Council House in which the street bridge was an essential; the composition forms an effective entrance to the street, but how the tower that completes the scheme would be balanced at the other end of the Council House Extension we are not shown.

"Town Hall, Chelsea: New Front to King's Road," by Mr. LEONARD STOKES, is a detail drawing of quiet and dignified work. "Cardiff County Hall: Detail of Front," by Mr. ALFRED W. S. CROSS, is another of the competition designs for Glamorgan County Offices, and rather too florid an example of detail. Messrs. WARWICK & HALL'S "Competition Design for Glamorgan County Hall: Detail," is yet one more from the same competition and an excellent example of good detail with some finely conceived large-size seated figures that form an integral portion of the design. A quaint conceit is the use of dolphins as supporters to balconies. Mr. FREDERICK J. LUCAS'S "Design for the Façade to a Club in Ferro-concrete" is a perspective drawing of the design that obtained first prize in the competition recently promoted by the *Builder*, and, being coloured, shows better than the original drawing in black-and-white the author's scheme of decorative use of material. Mr. A. GILBERT SCOTT'S "Design for Glamorgan County Hall" is a remarkable work in its external dignified and original composition. The plan is not shown. Mr. ROBERT ATKINSON'S "Cornwall County Offices, Truro," is another perspective of a competition design, which, though excellent in its grouping, may or may not have been accompanied by a good plan. These competition designs, without plans in which the essence of the competition con-

Digitized by Google

sisted, are merely academic studies of exteriors. The "Young Men's Christian Association, Manchester," by Messrs. WOODHOUSE, CORBETT & DEAN, is a curious design for that city, inasmuch as, from the coloured perspective, it appears that one principal element is the delicate combination of green stone in ground floor and bands with cream-coloured mass, perhaps, though the building is intended to be carried out in faïence.

NOTES AND COMMENTS.

THE danger of fire to St. Paul's Cathedral, to which we drew attention in our article on "The Fire Risks of London's Public Buildings" in our issue of February 12 last, has now received the careful attention of the Dean and Chapter, and they have decided on a scheme of high-pressure fire service prepared by Mr. MERVYN MACARTNEY to supplement the power that the fire brigade could bring to bear for the extinguishing of a fire at St. Paul's Cathedral. The cost of the fire-preventive measures proposed is estimated at 5,000*l.*, which is a moderate enough amount to pay as a capital expenditure to ensure the safety of London's civic cathedral. Appeal has been made by the Dean and Chapter to the Corporation and City Companies for assistance in carrying out this work and urgent repairs, and the matter has been referred to the Corn, Coal, and Finance Committee of the Corporation for consideration.

THE meeting of the Archæological and Architectural Society of Northumberland and Durham, which, as noted in our column of "Forthcoming Events," took place this week, embraced visits to places of considerable interest, as Lincluden Abbey, near Dumfries, formerly a Benedictine house, and of which there remain the choir, south transept, part of the nave, and some of the monastic buildings, as well as the fine tomb of the wife of the founder, daughter of King ROBERT III. Caerlaverock Castle, with its moat intact and full of water, is unique in Scotland. The house of Kirkconnell is a good example of a Border keep. Sweetheart Abbey, founded in 1284 by Lady DEVORGILLA OF GALLOWAY, wife of JOHN BALLIOL, to receive the embalmed heart of her lord, is one of the finest and best preserved of the monastic churches of Scotland.

IT is well to find an intelligent and wakeful public interest in the beauties of their respective localities manifested by the inhabitants, and we are therefore in sympathy with the protest of the residents of Southampton against the proposed or suggested erection of buildings on the western shore, which is one of the features of the town that go to make up for much of the ugliness inseparable apparently from a busy port and dockyard. Unfortunately, a little heat has been created by a reference of the protestants to an assurance believed by them to have been given by the Corporation to the Board of Trade, but denied by the Town Clerk.

LOCAL museums are undoubtedly worthy of encouragement, and in regard to these the advice given by Sir CHARLES HOLROYD in opening the new Weybridge Museum should be earnestly weighed and borne in mind by all who have in any degree to do with such museums. Commencing his argument from the proposition that all the most successful and vital museums are so by reason that they are distinctive and in some direction or other different from all other museums, he urged that a local museum should above all things be local; in this case it should illustrate Weybridge. This is sound advice, and if followed will preserve the local museum from being the dusty repository of a heterogeneous and incomplete collection of South Sea curiosities brought home by local sailor boys, useless for study or information, and occupying space that should be devoted to more suitable exhibits. One of the most difficult things for the managers of a local museum to learn is that they must be prepared to refuse offers of gifts from their local friends and not accept everything that is given. Better for the time empty cases and cupboards than unsuitable rubbish.

CLIENTS sometimes object to the high fees charged by professional men for valuations, and seem to think that all they should pay for is the bare value of the time spent by the surveyor in making his valuation. This, however, is not all that is paid for; there is also the risk of loss by reason of a mistaken idea of the value of the property in question. This has just been forcibly illustrated by the result of the action of CALLARD *v.* MAY and another.

IN this case Mr. ERNEST CALLARD, managing director of Messrs. CALLARD, STEWART & WATT, brought an action to recover damages from Messrs. STANLEY MAY & ARTHUR ROGER ROWDEN, auctioneers and surveyors, for negligence in advice given by them respecting the acquiring of certain property in Oxford Street. The result of the action was that Messrs. MAY & ROWDEN were mulcted in damages of 1,000*l.* and costs. It cannot be too widely known, especially by younger members of the architectural profession, that they incur a serious responsibility every time they make a valuation of property, and are liable to a claim for damages should the advice they give cause loss to their clients. They should therefore be chary of taking up such work at apparently remunerative fees below the usual scale, which is intended rightly to recompense professional valuers for the great responsibility they undertake.

THE question of Norwegian and British granite has again come up in the House of Commons, and seems now by reason of the action of the present Government to have become a party question, so that we have a member for Aberdeenshire, who is a Liberal, speaking in defence of the Government policy of using Norwegian granite to the detriment of his own constituents. It was stated in the House of Commons that the price of Norwegian granite for Rosyth Dock was 65,000*l.* as against 94,000*l.* for British, admittedly a serious difference.

THE tableaux organised by the Professors of Greek and of Archæology for the Hogarth Fair at University College, London, were not only archæologically correct, but really artistic productions, as indeed any faithful representation of Greek life might be expected to be. There is no doubt that such performances like pageants do teach history to a generation that no longer reads and studies serious books. We seem indeed to be returning to the methods of mediæval times when people were taught by pictures rather than by books, the only difference being that then they could not, now they will not, read books.

GERMAN RENAISSANCE ARCHITECTURE.

ALTHOUGH modern German architecture is deeply imbued with the feeling of the "New Art" movement, there is still a proper pride and appreciation of the national architecture of Germany as exhibited in the buildings of the sixteenth and seventeenth centuries, and hence a reason for the publication of yet another work * on the particular phase of Renaissance architecture that dominated Central and Northern Europe from east to west during those centuries. The merit of the book now before us lies in the fact that it is less monumental and ponderous than many tomes that have preceded it; so that while it gives an adequate and satisfying purview of the German Renaissance by means of excellent photographic plates, this has been accomplished at quite a moderate price by the exclusion of learned and scientific analytical disquisitions upon schools and influences, periods and development, and all the other divisions and subdivisions that delight the architectural historian.

The examples chosen for illustration are gathered from all parts of German-speaking Europe, from Danzic to

* *Baukunst und Dekorative Skulptur der Renaissance in Deutschland.* Herausgegeben von Julius Hoffmann, mit einer Einleitung von Dr. Ing. Paul Klopfer. (Stuttgart: Julius Hoffmann. 25*s.*)

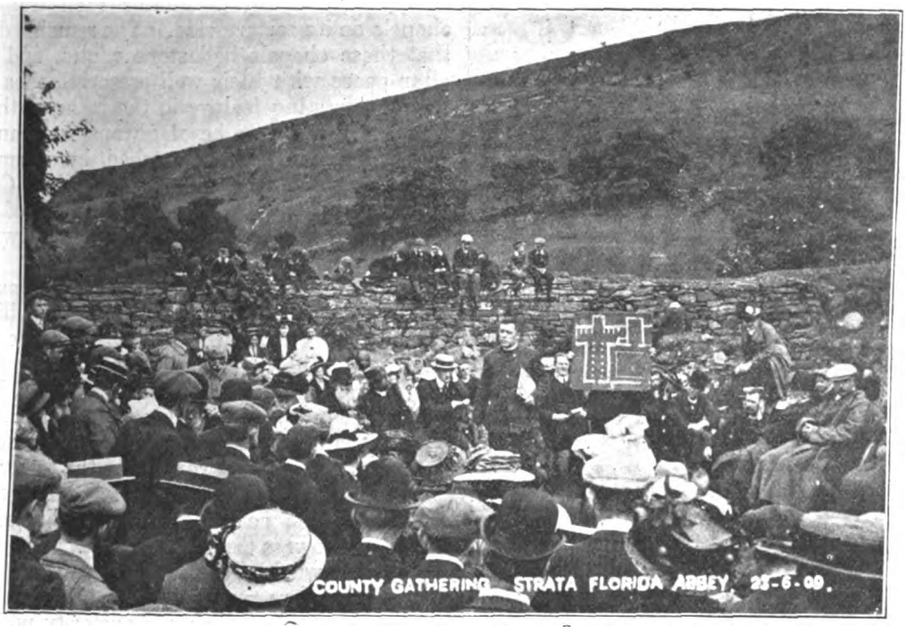
HEIDELBERG.—THE HOUSE "ZUM RITTER" BEFORE RESTORATION.

Munich, from Strasburg to Ulm, and include specimens of Renaissance work in stone, brick, timber and slate. The peculiar treatment of half-timber work in the Duchy of Brunswick and the Kingdom of Saxony is well illustrated, the early work of Heidelberg, the charmingly picturesque buildings of Rothenburg, as well as the more generally known ones of Nuremberg. Many instances are shown of the sculpture that was so considerable an element of the German Renaissance, as well as of the particular features of various towns, the gables, the dormers, the oriels and the towers which predominate in each, for it is characteristic of German towns that certain forms are especially favoured in each, a noticeable point, for example, being the roof treatment, particularly of the ridge, which in some cities, as Nuremberg, is usually, parallel to the street, hence leading to the development of the dormer; in others at right-angles to the frontage, and so causing gables to predominate, as at Landshut,

Digitized by Google

OSNABRÜCH.—HOUSES IN THE BIERSTRASSE.

although in this instance there are not included in this book any examples of such treatment from this particular town. Still, there are plenty of examples of the characteristic treatment of gables, as of every other feature. Ecclesiastical buildings, as well as domestic and municipal, furnish the sources from which the work illustrated is taken, so that, alike as regards locality, material and purpose, a thoroughly representative collection of examples is included, adequately showing both the general character as well as the various types of treatment and development of features, and methods of craftsmanship are brought before us. Thus we have in the form of illustrations the results of the German Renaissance movement in architecture which, if we allow that it started from the basis of the HENRI QUATRE period of French work, was ever national in its development, influenced by the characteristics of German temperament and high technical skill in craftsmanship as well as by the forms of German mediæval work, and, after its first inception, remarkably free from foreign influence, Italian, French or Flemish. Indeed, as regards this last, we can readily believe that it was Germany that gave the lead to Flanders and Holland rather than the reverse.



The fact that this book contains a minimum of text with a maximum of 360 illustrations, and these excellent, should particularly commend it to the many British architects and architectural students whose knowledge of the German language has deteriorated from the time of their schooldays. Everyone can understand photographs even if they cannot read the German language with readiness and ease. We have therefore no hesitation in strongly recommending this book to all those who care to know what were the excellences and the developments of the German Renaissance. Although its position in the domain of art may be discredited by the purist, it possesses many admirable characteristics of its own—picturesqueness, inventiveness, independence and earnestness combined with an evident enjoyment of the craftsman in his work that cannot fail to create interest and arouse appreciation. We are indebted to the publisher for permission to reproduce two of the illustrations in the book, which may be taken as a fair sample of the 360 included.

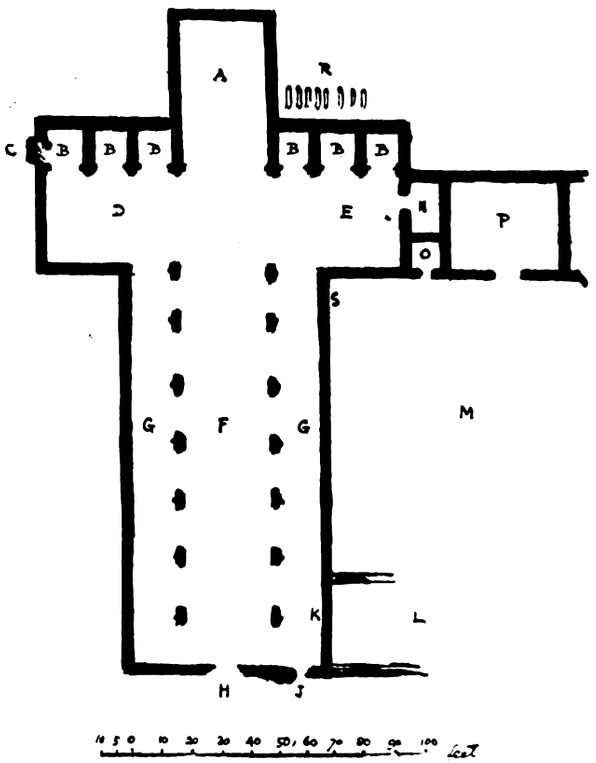
THE ABBEY OF STRATA FLORIDA, CARDIGANSHIRE.

By the Rev. Professor E. TYRRELL GREEN.

THE abbey of Strata Florida belonged to the Cistercian Order. Monasticism was introduced into Europe in the fourth century, but in process of time the monks lost their ascetic ardour, rules were not faithfully observed, and the "religious" life deteriorated. St. BENEDICT (A.D. 480-540) reformed the monastic rule, and the system inaugurated by him, and known as the Benedictine rule, became the standard of the "religious" life, in the technical sense, for all time. For six centuries (A.D. 500-1100) the Benedictine was the sole monastic rule in Europe, and later Orders, such as the Cluniac and Cistercian, were really reformed Benedictines. Towards the close of the eleventh century the observance of the Benedictine rule had in some parts been relaxed, and seeing that the life of the monks tended to lose its ascetic fervour and devotion a reformation was instituted by a few monks who, under the guidance of ROBERT OF MOLESME, moved to a new abbey founded at Citeaux (*Latin* Cistercium), near Dijon in Burgundy, in 1098. The Order of reformed Benedictines thus instituted became known as the Cistercian from the name of its first monastery. The power of the Order was due partly to the revival of a very simple and austere life by the monks, but it also lay in their splendid organisation, which was the work of STEPHEN HARDING, an Englishman, second Abbot of Citeaux. St. BERNARD belonged to the new Order, joining it in 1113, and was made Abbot of Clairvaux in 1119: to him the position of great influence which the Order rapidly attained is chiefly due. He was the embodiment of all that was best in the thought of the age: he was brave and pure and consumed by a passion for the moral welfare of the people. He practically ruled Western Europe: he was arbiter in Papal elections, judge in temporal quarrels, healer of schisms, and preacher of the Crusades. It was said of him that when St. BERNARD was by mothers hid their sons and husbands their wives lest they should be persuaded by his eloquence to enter the cloister. The Cistercian Order thus gathered by ROBERT OF MOLESME, organised by STEPHEN HARDING, and inspired by BERNARD OF CLAIRVAUX, spread rapidly: it is computed that within fifty years 500 houses were founded, and in another fifty the number had increased to 1,500. The first Cistercian house in England was established at Waverley (Surrey) in 1128. Then followed the foundation of the great monasteries at Rievaulx (1131), Fountains (1135), Furness (1148), Kirkstall (1152), Roche (1165), Byland (1170), and Jervaulx (1180), all in the north of England. Beaulieu (1221) and Netley (1239), in Hampshire, were established a little later. The lovely abbey at Tintern was built later still (1269). The chief houses belonging to the Order in Wales besides Strata Florida were Valle Crucis (Denbighshire, 1200), Cwmhir (Radnorshire, 1143), and Margam (Glamorganshire, 1147). The chief Cistercian monasteries in this country are remarkable for the beauty of their position and surroundings, being situated in remote spots and in narrow, secluded valleys, in conformity with the rule of the Order, which laid down "in civitatibus, in castellis aut villis nulla nostra construenda sunt cœnobia, sed in locis a conversatione hominum semotis." The Cistercian rule was marked by a stern simplicity and austerity of life: only one meal a day was allowed during a great part of the year; meat was never eaten, fish only occasionally; hours of silence were enjoined, the wearing of shirts, gloves, and boots was forbidden, and the monks engaged in manual labour, becoming especially skilled agriculturists and horticulturists. The spirit of the Order found its outward expression in the severe simplicity of the architecture of its churches; it held up before men the sternest mode of life as the ideal and refused the appeal of elaborate ritual and splendid art. Thus for many years the Cistercian abbeys were characterised by a rejection of the richness and beauty which men commonly lavished on the sanctuary. By the rules of the Order stone bell-towers were forbidden, nor might the wooden belfry be a structure of any considerable size; human heads or any representation of the human figure were not allowed in the carving of the church, other than statues of Our Lord Himself or figures of the Crucifix. The windows were not to be filled with stained glass. The vestments used at the altar were to be of coarse linen, and precious metals or jewels were not allowed for the sacred vessels; even the chalice and paten at the altar might be of no more costly material than silver-gilt. It is true that this twelfth-century Puritanism in time outgrew its fear of beauty, and its laws in this respect were not so strictly kept, yet simplicity and restraint remained characteristic of the Order and are very marked features of the architecture of its earlier abbey churches, such as Furness, Fountains, Kirkstall, and of this at Strata Florida.



The abbey of Strata Florida was founded on its present site (there had apparently been an earlier monastery at a spot about two miles off, still known as Hen Mynachlog) by RHYS AP CRUFFYDD, Prince of South Wales 1164-6. The precise date is not clear, but in 1184 a charter was given to the abbey by the same Prince, confirming previous gifts. The great church was in building when Archbishop BALDWIN of Canterbury stayed at the abbey on his tour through Wales in 1188 preaching the Crusade, and it seems to have been completed in 1201.

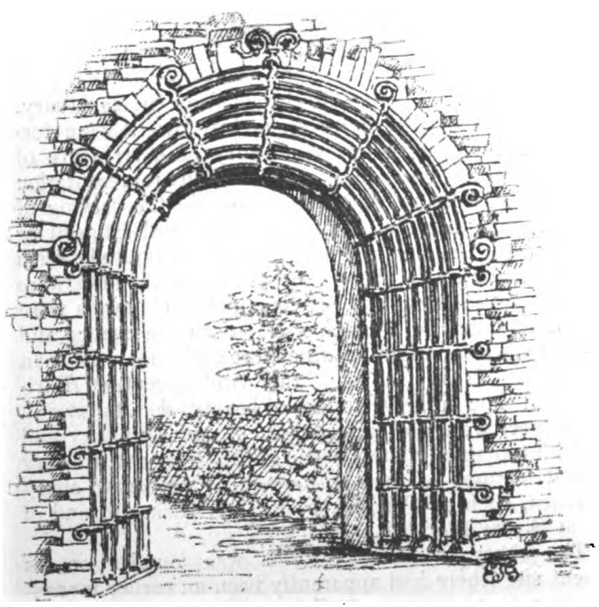
PLAN OF THE CHURCH.



The plan of Strata Florida shows a typical Cistercian abbey church, having all the striking peculiarities which marked the architecture of the Order.

(A)—*Rectangular and Aisleless Choir.*—While, like most of the greater churches of the time, the Cistercian abbey churches were cruciform, the choir was as a rule rather short in proportion to the rest of the building, rectangular in its termination at the east end, and a simple parallelogram on the plan, without aisles, projecting chapels, or procession path behind the high altar. Strata Florida furnishes an excellent example of this simple plan for the choir. The Romanesque builders of Western Europe generally used the apsidal chancel, as seen, *e.g.*, in some of the great Norman churches in England, such as Norwich and Peterborough cathedrals. This plan was often complicated in the greater churches by carrying the choir aisle all round the apse and by the addition of a number of radiating chapels at the east end. But Citeaux, the mother church of the Cistercian Order, was a church of a simple Burgundian Romanesque type, with rectangular choir, and this became the pattern plan for the abbey churches of the Order, to which there are few exceptions. The persistence of the rectangular east end in English architecture has often been remarked, and forms one of the obvious points of contrast between English and Continental church architecture, the apse (polygonal or semicircular on the plan) being on the Continent the usual termination for the choir. Amongst the causes which determined the English preference for the square-ended chancel it is likely enough that we ought to reckon the influence exercised upon our national style by the great Cistercian abbeys of the twelfth century.

WEST DOOR.

(B)—*Range of Chapels to the Transept.*—Another peculiarity of the Cistercian churches, well illustrated at Strata Florida, is the row of chapels, two, or more often three, in number, ranged along the east side of each transept, and separated from each other by solid walls of masonry. The transepts are without aisles (like the choir), and at Strata Florida each transept has three chapels on its eastern side. The remains discovered show that these chapels had stone vaults, and the altars and altar paces with their well-preserved tiles *in situ* form a most interesting feature in the ruins of the abbey. The tiles are thought to be of Shropshire manufacture, their patterns having been matched by examples found at Shrewsbury Abbey and at Tong and Cound (both in Shropshire). A date about the middle of the fourteenth century is indicated by the costume shown in the figure of a man borne by some of these tiles.

(C)—*Absence of Tower.*—Allusion has been made to the rule of the Cistercian Order by which stone bell-towers were excluded. One of the first reasons which led to the building of towers to churches was, of course, to provide a suitable structure for the bells, but it is equally clear that many early bell-towers are both taller and more ornate than was necessary for this purpose. It was often in the height and adornment of the tower that the power and influence of the founder of a church or the prosperity of a monastic corporation was indicated to the world. Thus bell-towers came to be looked upon as emblematic of pride and wealth, and they were therefore regarded by those who were responsible for the Cistercian rule as out of keeping with the simple austerity which should mark the Order. The builders of Strata Florida seem to have been true to their regulations. There are no traces of western towers observable, and if there was any structure rising above the level of the roof at the junction of nave, choir, and transepts it could only have been a low lantern, because the piers at the crossing, when compared with the piers of the nave arcade, give no evidence of that extra thickening which would have been necessary had they been intended to carry the weight of a central tower. It was only at a much later period than that to which the structure at Strata Florida belongs that, in violation of the doctrine and discipline of the Order, towers were added to some Cistercian abbey churches, as at Fountains and Kirkstall.

STYLE OF ARCHITECTURE.

It was in the latter half of the twelfth century that many of the great Cistercian abbeys were built, and this was a period of transition in architecture. It was at that time that the pointed arch began to be used by the builders of Western Europe, though the general character of their structures remained unchanged, together with most of the detail and ornament, so that between the Romanesque (or Norman, as we generally call it in this country) and the pointed styles there intervened a transition period when architectural style was still in its general character Romanesque, but the arch took the pointed shape, especially when used in construction, smaller arched openings such as doorways or windows

Digitized by Google

often remaining round-headed. Thus, both at Kirkstall and Fountains, the massive piers which divide the nave from the aisles bear pointed arches, while windows and doorways have semicircular arches, the doorways having deeply recessed and moulded arches quite in the Norman manner. The somewhat scanty remains at Strata Florida, oddly enough, contain in the west wall one arch of each kind, the semicircular arch of the great door and the pointed arch of the window to the south of it, thus showing that the church here was of the same transition style as the great churches of the Order named above, though built a little later.

A peculiarity of Cistercian churches (or at any rate of the earlier ones) was the absence of human heads or figures in the carved work. This was by rule of the Order. In the tympana of Norman doorways and in the richly moulded semicircular arches of the later Norman style figures of men, animals, and fearsome beasts often occur. In the numerous abbey churches of the Cistercians built during the first two centuries of the existence of the Order there are few, if any, exceptions to the rule which forbade decorative representations of the kind, while, on the contrary, human figures carved in stone abound in contemporaneous buildings belonging to other Orders. The capitals of pillars, for example, were often elaborately carved with illustrations of incidents from Scripture story, like the wonderful series in the richly adorned Romanesque church of St. Denis at Amboise. But the Cistercian churches had an air of solemn and severe grandeur, superfluous or ornate carving being as a rule excluded, and the capitals being ornamented only with a plain scallop (as at Fountains) or with simple mouldings (as at Tintern). The carved work at Strata Florida is exceptional. The capitals and other carved portions show a decided tendency to interlacing ornament, such as we see in Celtic manuscripts and in early Celtic crosses, such as the fine examples at Nevern and Carew in Pembrokeshire and at Llanbadarn Vawr in Cardiganshire. The same kind of interlacing ornament may be seen, too, on the crosses which mark the graves in the monks' cemetery at Strata Florida. Yet another feature at the abbey which suggests the influence of early Celtic art is the very peculiar adornment of the splendid west door to the nave, where the mouldings run all round without any capitals, as in some Irish examples, and the unique transverse bands terminate in scrolls or curls somewhat resembling a pastoral staff.

The fact that the rubble of the walls at Strata Florida has been very roughly put together renders it probable that the church was plastered on the outside, as it certainly was internally. The "putlog holes" are still plainly to be seen in the fragment of the west wall of the church that is standing. These holes go right through the wall, and into them logs of timber were inserted upon which planks were placed as a scaffold, the use of scaffold poles being thus avoided. The "putlog holes" were not closed up when the building was completed, but were left open so that the monks could at any time repair any portion of the wall without the trouble and expense of erecting an elaborate scaffold.

THE DOMESTIC AND OTHER BUILDINGS.

As was almost invariably the case in Cistercian houses, the domestic buildings at Strata Florida lay to the south of the church. Immediately to the south of the nave was the cloister, and from this a door in its north-east angle led into the church. The chapter house was entered from the east walk of the cloister. This was a rectangular building lighted from the east, with seats round the walls for the monks in chapter assembled. The space between the south transept of the church and the chapter house was divided into two parts by a partition wall: the eastern portion of this space was the sacristy and communicated with the church by a doorway in the south wall of the transept. The western part of the space seems to have been an unlighted cell. A similar cell occupies an analogous position in the plan of almost all Cistercian monasteries, and its use cannot be determined with anything like certainty; it is thought, however, that it may have been a punishment cell for monks who had been guilty of some breach of the rules of the Order. In the angle between the choir and the south transept was situated the monks' cemetery, and during the excavations conducted under Mr. STEPHEN WILLIAMS, F.R.I.B.A., in 1887-8 a most interesting series of graves of the monks was brought to light. These are covered with rather rough slabs of local stone, one of which has an incised cross. Some of the tombs have their carved head-stones still *in situ*: these take the form of small crosses and are adorned with interlacing patterns of a Celtic type.

On the west side of the cloister, and in line with the west front of the church, was the usual place for the Domus Conversorum, or house of the lay brethren, in a Cistercian monastery. The staircase near the west end of the south aisle, which led from the church to this building, may still be traced at Strata Florida.

While the position of the chapter house, sacristy, and cloister have, through the researches of Mr. STEPHEN WILLIAMS, been clearly defined, the domestic buildings at Strata Florida have not been thoroughly excavated, and are somewhat difficult to trace. This is probably due in some measure to the fact that the abbey suffered greatly, in the first place, through more than one fire—an accidental one through lightning in 1284, and again when burnt by the English soldiery in the Welsh wars of EDWARD I. (1294). The abbey suffered perhaps even more through being used as a military post, when, during and for some time after the troubles caused by the rising of OWEN GLYNDWR, it was occupied by a garrison of archers and men-at-arms in the reigns of HENRY IV. and HENRY V.

Long before the dissolution of the monasteries many of the buildings seem to have been in ruins. But, notwithstanding the devastation of fire and sword, in spite of the centuries of neglect and decay since the dissolution of the monastery, and although its stones must often have served as a quarry for farm and other buildings in the neighbourhood, enough still remains of the once stately church of Strata Florida to show that, like the other great churches of the same Order, its construction and decoration alike evidenced that ascetic ardour, that temperate good taste, that straightforward procedure and practical utility which characterised the Cistercian rule.

KEBLE COLLEGE, OXFORD.*

By D. J. MEDLEY, M.A.

KEBLE COLLEGE was opened in 1870. It was the outcome of a movement which had begun as early as 1845. In that year a memorial was presented to the Hebdomadal Board embodying the views of a number of influential persons that, in the interests of the Church, it was necessary to put the means of higher education within the reach of those who could not afford the expense of residence at the existing Colleges. Among the signatures to this memorial are those of Lord ASHLEY (afterwards Lord SHAFTESBURY), Mr. GLADSTONE, Dr. PUSEY, and A. C. TAIT, the future Primate. But it was twenty years before the matter took actual shape. In the interval, however, there had been growing a strong feeling of the need "for the extension of the University in some form or another." Ultimately a meeting was held on November 16, 1865, in the hall of Oriel College under the chairmanship of the Provost, "to consider the question of the extension of the University, with a view especially to the education of persons needing assistance and desirous of admission into the Christian ministry." It will be seen that the scope of the question had been somewhat enlarged in the twenty years since the presentation of the memorial. At the meeting six sub-committees were appointed to deal respectively with the subjects of the foundation of a new large College, the adaptation of the existing Colleges, residence in lodgings either with or without connection with the existing Colleges, the needs of poor medical students, the affiliation of other places of liberal education. Of these the first sub-committee alone concerns us. It con-

sisted of seven clergymen—Dr. SHIRLEY (the chairman), Dr. PUSEY, Professor MANSEL, and the Revs. R. GRESWELL, J. RIDDELL, J. W. BURGON and W. INCE, together with two laymen, Professors BERNARD and BURROWS. It is interesting to note the points in the scheme which they formulated. They considered that it would be practicable to found a new College or Hall and to conduct it on a scale of charges lower than was prevalent in the existing Colleges under the following conditions:—The rooms should be smaller than were usual in the other Colleges, and should be furnished at the expense of the College; they should be arranged along corridors instead of by staircases—a method which the committee believed "to be not only more economical, but intrinsically superior, more comfortable and better adapted to modern habits of life." Breakfast as well as dinner was to be served in the College Hall. Caution money and entrance-fees should be materially reduced if not abolished. Everything necessary to living in ordinary comfort should be included in one fixed terminal payment, and a limit "narrower than is usual in most Colleges" should be fixed to the amount of extra battels. The committee was, however, careful to remark that in their recommendations they did not contemplate the establishment of a "Poor Man's Hall"—that is, "of such an eleemosynary establishment as would be sought only by persons of inferior social position, less cultivated manners or attainments and intellect below the ordinary level of the University, but rather of one which is adapted to the natural habits and tastes of gentlemen who wish to live economically." All these suggestions were carried out in the arrangements of Keble College. The rooms are smaller than is usual in the older Colleges, they are furnished at the expense of the College and are arranged along corridors. Breakfast, lunch and dinner are all served in the Hall except for those who are on the sick-list. There is no caution money and only a small entrance-fee; but tuition, board and lodging are all paid for in one fixed terminal payment, and there are restrictions on such extra expenditure as may be incurred through the College kitchen. Time has no doubt produced certain modifications in the original arrangements. The formation of the building was found to lend itself to an undue amount of social intercourse, and yet while the partition of the corridors reproduced in a somewhat modified form the staircase system of the older Colleges, a small passage in the partition still made possible that ease of service on which the economical working of the College so largely depends. Again, although many fathers found it possible to send their sons to Oxford because of the reduced expense, the new College from the first contained an appreciable number of men who would have come to the University in any case. There are some critics of the new College who maintain that it is possible for an undergraduate to live as cheaply at several of the older Colleges as he can live at Keble. Possibly it is so; but one who knows the life at Keble both as undergraduate and as don is inclined to doubt whether equal social advantages are to be purchased elsewhere for the comparatively moderate sum which will carry a man comfortably through his time at Keble. Moreover, it cannot be denied that there is no College at which the *general* standard of expenditure is pitched so low.

ILLUSTRATIONS.

COMPETITION DESIGN FOR MIDDLESBROUGH PUBLIC LIBRARY. BY WILLIAM HAYWOOD.

IN this scheme the library is entirely isolated, the space at the side of the juveniles' library serving to isolate the building against risk of fire from adjoining property. The committee's requirements, although in some respects unusual and difficult, have been successfully embodied in a simple and straightforward plan: special attention is called to the cross ventilation of every room. *The Plan.*—The lending library is suitable for either open access or indicator systems. It is well lighted from opposite sides by windows which reach the ceiling, providing a total glass area of 480 square feet to 2,590 square feet of floor area. The shelving shown upon the plans accommodates 30,000 volumes, but 40,000 could be shelved without difficulty. The entrance to juveniles' library is well removed from the main entrance; the portions screened off for boys and girls are served from a common counter, the attendant being under supervision from, and within easy communication of, the lending service for adults. The shelves reserved for juvenile literature accommodate 5,000 volumes. The news room has windows on all sides; no top lights are considered necessary, although the roof is entirely available for that purpose as directed. The room and its entrance are under the direct supervision of the janitor. The janitor's room also controls the ladies' room and the main entrance. The service hall, book lift, and stairs (the stairs are in straight flights), the work room, staff room, lavatories, files room, and store rooms are all compactly and economically planned, yet in close touch with every department, and under the immediate control of the chief librarian. The reference library is entered directly from the upper hall: it is a room of considerable architectural importance, an importance largely due to the way in which the future extension has been provided for. The gain is not only in appearance, but the supervision is perfect, and an extended gallery also has been obtained. The lighting is from the top (single glass roof lighting as directed), with clerestory windows to give cross ventilation. The wall cases on floor and gallery combined will shelve 30,200 volumes. The librarian's room is in contact with the law library, reference library, main stairs, service stairs, and staff rooms. The files room is on the same level as gallery, and a large store is provided in the roof. The elevations have a classical and refined appearance. The design grows naturally out of the plan, which is clearly indicated in the external features of the building, and the proportions and relative values have been carefully adjusted by means of a clay model. It is proposed to use Portland stone for the frontages to Dunning Street and Grange Road, with local bricks elsewhere. *Estimate*:—Cubical contents, 303,528 cubic feet at 9½*d.*, 12,014*l.* 13*s.*; railings, &c., to Grange Road, 150*l.*; total, 12,164*l.* 13*s.*

COMPETITION DESIGN FOR MIDDLESBROUGH PUBLIC LIBRARY. BY JOHN H. MARKHAM, A.R.I.B.A.

THE cost of the building was stipulated to be not more than 12,000*l.*, and the particulars of accommodation required fixed the position of the three principal rooms in such a way as to greatly hamper the designer. The lending library and reference library over were to adjoin the old buildings at the north end of the site, and the general news room was to be a one-storey building with a separate entrance, and was to be at the corner of Grange Road and Poplar Street. These requirements left only a few smaller rooms to be arranged by the competitors, and the areas required were such that the space left for corridors and staircases was quite insufficient for a building of any importance. In the design submitted by Mr. JOHN H. MARKHAM, of 2 Gray's Inn Square, W.C., the elevations were kept very plain, as it was necessary to cube the building at 8½*d.* in order that it might be carried out for the sum allowed. Any attempt to obtain absolute symmetry would have meant forcing the plan somewhat, as it was distinctly stated that there were to be no windows in the reference library, and windows seemed very desirable in the corresponding rooms on the other side. The materials were red brick and stone.

EXHIBITION OF COTTAGE DESIGNS, MANCHESTER.

THE Royal Manchester Institution has promoted a very interesting and instructive exhibition of designs for cottages, and these are now on view in the City Art Gallery in Moseley Street. As the collection is free, it is clear that the scheme is purely for educational purposes, and as such it seems to be appreciated and should have a practical value and effect upon work done in the busy industrial district of which Manchester is the centre.

The designs show clearly that a practical point in cottage planning has been reached; no longer is the problem in the Lady Bountiful or model-village stage, for no matter how much praise is given to those landed proprietors whose desire for a pretty village often caused them to lay out capital in an unproductive way, practical builders know that the only true solution must be to produce buildings that not only exactly fit the requirements of the inhabitants, but also on a reasonable expenditure provide a fair return for the money spent.

In fitting the requirements there are certain essentials to be borne in mind, and as these essentials vary in different localities, either through custom or climate, it follows that any architect having received a commission to design such buildings should first of all make himself thoroughly familiar with the local notions, otherwise he will probably injure his client in not securing a fair return for his outlay. Three bedrooms should always be provided, but the question of the "parlour," so loved in many localities, seems to have been avoided in most of the plans. Experience shows that it is not an acceptable thing to put a good big living room at the front and a small parlour behind; the tenant will in most cases reverse the architect's notion and crowd his family into the small room, keeping the front room as the parlour. However foolish this notion may appear to those accustomed to larger houses, it is a real difficulty that must be met if the property is to let well. It is no good pointing out to them how much more cheerful, healthy and comfortable it is to have a big room at the front and no best room for very occasional use. The fact remains that such a room is ardently desired, and this desire ought certainly to be met.

To turn to the designs themselves, they are of great value to any student by reason of their being drawings of executed work, and the actual cost of many of them is given. No. 1 (J. Wornell, Slough) is a simple treatment in rough cast and tile, but the bedrooms are very small. No. 2 (A. W. Worrall, Wolverhampton) is a pleasing design, but the staircase is dark. No. 3 (Parker & Unwin) is more ambitious, and provides a bath-room, but again the stairs are dark. No. 4, by the same authors—a pair of parlour cottages at Fortune Hill, Hampstead—is a beautiful example of architectural draughtsmanship and is also a very pleasing design, but again the stairs are dark and the windows generally are too small; probably they comply with the minimum permitted by the by-laws in force in the locality, but in the North of England such small windows would act as a deterrent to letting.

No. 5, by the same authors, is an ingenious adaptation of two and three bedroom houses dovetailed into one another, but the effect suggests a tenement house. No. 6, by the same authors, has bedrooms 6 feet 1½ inches wide between walls, and these rooms would be little more than cupboards, and the grouping suggests a charitable institution, and this surely is the last thing to be aimed at. Ordinary folk want a house to look like a home.

No. 8—same authors—has a very small kitchen, about 7 feet by 8 feet, and lit only in one corner. This plan is not worthy of the authors.

No. 10—same architects—is a much more successful solution. The houses look like a home and not an institution, but the windows might be bigger. The cost is, however, somewhat high; 306*l.* without land cubes out at 6*d.*—rather high for industrial purposes.

No. 11, by Geoffrey Lucas, is a very pretty design, but really Mr. Lucas would not like to pass a few days on a sick bed in one of the bedrooms; he would find it the reverse of cheerful. The only practical place for the bed is 20 feet away from a small window, and that again is a dormer deeply set in the lean-to of the roof.

No. 13, by J. A. Hallam, is a single cottage at Letchworth. A photograph shows an exceedingly pretty living room interior, but the principal bedroom is just 20 feet long by 12 feet wide and is lit by two deeply recessed dormers, which cut up the room so much that the only place for the bed is in a dark corner against the slope of roof. If the furniture had been planned in the rooms, instead of trouble taken to show the stone or tile paving outside, such a grave fault as this would have been avoided.

No. 14 (Baillie Scott) is a stagey affectation and by no means to be taken as a serious solution of an ever-pressing problem.

No. 15 (Parker & Unwin), a pair of thatched cottages erected in a place where no by-laws exist, is an object-lesson of the necessity of such laws. Tiny windows and bedrooms whose sloping ceilings come to within 4 feet of the floor are not desirable, by-laws or no by-laws.

No. 17 (R. Bennett & W. Bidwell), a block of six cottages. A nice simple treatment, but the central cottages have very cramped entrances and the stairs are dark.

No. 21 (same authors) has three good square bedrooms, a living room and kitchen; but let the authors try to deliver the coals into the small door provided for that purpose, its sill being 4 feet from the ground. Such homely details require attention.

Nos. 27, 28 and 29 (Edgar Wood), a row of houses at Middleton. The doors, directly opposite one another at each end of side passage, ensure a very good draught in such an exposed situation, and the treatment of the shop in No. 29 is very fidgety. The simple treatment of No. 27 is much happier.

Exhibit No. 30 consists of two large sheets, and is an academical compilation by a committee of the Manchester Association of Architects to show how a certain locality could be laid out. It is a very praiseworthy attempt and reflects great credit upon the Association. It is suggested that so many Oriental domes would become a bit monotonous, and indeed are hardly suitable to the locality.

Nos. 31 and 32, four cottages at Earswick, would give trouble unless the coal cellar, earth closet, and entrance doors were clearly labelled.

Nos. 36 and 37 (by Spiers & Beavan, Cardiff) are well planned and picturesque in elevation, whilst the photograph of the actual building shows how very successful the authors have been.

Nos. 39, 40 and 41 (W. R. Mosley, Cardiff) are very pleasing. The rooms are of good size and square, the staircases have windows, and the cost is reasonable.

Nos. 42 and 43 (G. Fraser, Liverpool) are lodges, but as they cost 700*l.* each, with only cottage accommodation, do not really come into the problem. The elevations are carefully designed.

No. 48 (A. Randall Wells) is one of the most pleasing designs in the exhibition. It is good value for the money (305*l.*), and shows a long house, and there is much to say for such a plan if land is cheap, as all rooms get abundant lighting and there is a chance to avoid any dark places. Other designs by the same author are on the same lines, and all are pleasing.

No. 53, a group of cottages at Port Sunlight (Bradshaw & Gass, Bolton). These are only suitable for a millionaire's purse, and are cut up so unnecessarily that the result is a jumble, whilst the flashy colouring only serves to emphasise the defect of design. A far better rendering of this design is the coloured perspective hanging below it.

Nos. 54 and 55 (W. Owen, Warrington), another Port Sunlight group, is very restrained, magazine detail being carefully avoided, whilst the photograph of the executed work confirms the restful, quiet effect.

No. 59, Port Sunlight (Ormerod & Pomeroy, Bolton), a clever, up-to-date drawing such as would attract a competition committee; but the photograph of the actual work reveals how very different the real effect is from that suggested by the drawings.

Nos. 63, 64 and 65 are more Port Sunlight cottages, by Messrs. Ernest George & Yeates, and are delightful designs, full of restraint and good feeling; the only fault to be found is the dark staircases. No. 67, at same place, by Douglas & Minshull, is a masterly design, very homelike and quiet, but rather expensive.

Nos. 69 and 70 (T. T. Rees) are very nice and quiet and the cost reasonable, but the bedroom oriels in No. 70 are too small for their purpose.

No. 72 (H. B. Bare, Liverpool) is an actual working drawing, not a sketch for exhibition, and is therefore very interesting to architects. The accommodation is all that could be desired, but the cost per cottage—386*l.*—seems rather too much for the purpose.

In another part of the Art Gallery the Manchester Academy of Fine Arts are holding their jubilee exhibition, and amongst the pictures are some works by architects that are well worth examination.

No. 2, a design for the Manchester Town Hall by the late E. Salomans, is not a happy design; whilst No. 42, a water-

Digitized by Google

colour of Jumièges Abbey by the same hand, is a most delightful work, one that the visitor will return to with pleasure.

No. 7, a large perspective drawing of the Clock Tower, Manchester Town Hall, by the late A. Waterhouse, in his well-known and vigorous draughtsmanship. Its strong lines and characteristic brown tones seem just the thing to express an architectural design, and are well worthy the consideration of the younger generation of exhibitors of cottage plans. Here are no dodges, but good direct draughtsmanship.

No. 11, a brown wash detail study of the entrance to Ashby Folville Manor, by John Ely, is a beautiful design, most artistically drawn, and this again may be commended to the modern draughtsman as an example worth following.

No. 12 is a rather thin design for rebuilding Manchester Cathedral, by the late Isaac Holden. One cannot regret that it never came to fruition.

No. 18 is a sketch for the Manchester Town Hall by A. Waterhouse; probably an alternative design that certainly justifies the selection made by the Corporation.

No. 23, a rather hot drawing of Hulme Grammar School by A. H. Davies Colley. It was erected in 1886, and marks the progress made in such work since that time. It is doubtful whether it would be erected now.

No. 44, a sketch in Winchester Cathedral, by John Ely, is a beautiful work, evidently a labour of love on the author's part. Nos. 68 and 72 are sketches in Venice by W. H. Littlewood, and are both capitally rendered. Possibly the colour in No. 72 has faded since 1896, but allowing for that it is a fine work.

No. 83, by the late A. Darbyshire, is a brightly coloured drawing of Brereton Hall. The perspective is a trifle loose, but all the same it is a careful study of a delightful bit of old work.

TOWN PLANNING IN WIESBADEN.

THE National Housing Reform Council, it will be remembered, organised a party numbering eighty-six to visit and study examples of town planning in Germany in April last. Among the various municipalities represented was Birmingham, who sent a deputation of the housing committee. The deputation have just issued their report on Cologne, Düsseldorf, Wiesbaden, Frankfort-on-Main and Nuremberg. These towns had their own peculiar problems to solve, and the report indicates the different character of each. The account of the visit to Wiesbaden is of special interest. It is certainly true when the deputation remarks that "inasmuch as Wiesbaden is not an industrial town it is perhaps not very valuable for the purpose of comparison with Birmingham, but it is a splendid example of how a town can be made beautiful by foresight in planning." For this reason this part of the report will be specially interesting to our readers. Moreover, it includes an address by one of the best-known authorities on town planning, which deals with the subject as a whole.

Wiesbaden is a town of 104,522 inhabitants, with an area of 9,000 acres, 3,540 of which are owned by the municipality.

Wiesbaden started its town planning by planning a district at a time, but it was ultimately found that to do the work satisfactorily, a comprehensive scheme must be made for the whole town. This was done, and the town divided into a number of different districts for statistical and development purposes. Bye-laws were made to suit the likely requirements of each district, regard being had in particular to the price of land in each district. This was fully explained by Professor Eberstadt, a leading authority on town planning, who delivered the following address to the party:—

"In comparing Wiesbaden with the other towns which you have visited or will visit, the most important point to bear in mind is the extreme rapidity of its development into a large town, which has taken place within the last twenty-five years.

"Before a general building plan was drawn up for Wiesbaden, building plans had already been devised for smaller districts to meet the needs of the moment. At the beginning of the nineties, a building plan based upon a judgment delivered by Professor Baumeister, of Karlsruhe, was drawn up, comprehending the whole area of the town as far as the outside parishes.

"This judgment, with its general guiding principles, together with the experience gained in the meantime, and the rules based upon the science of town planning, served to indicate the lines to be followed in drawing up the special building plans, a task which is now nearly accomplished. The land round the nucleus of the town, before the building plans were drawn up, was agricultural land, such as we still see in the environs of Wiesbaden. This land was, for the most part, in the private possession of citizens of Wiesbaden. The owners on each side were compelled, in accordance with the Prussian Building Lines Act of July 2, 1875, to provide the land required for the laying down of streets up to a limit of 6 metres in width, without compensation.

"The width of the streets varies enormously, according to their position and importance, their gradients, and the traffic which they are intended to serve. New streets are, as a rule, laid down with breadth as follows:—Dwelling streets, 9.50 to 13.50 metres; secondary traffic streets, 13.50 to 24.00 metres; circular streets, 26.00 to 37.50 metres; chief traffic streets, 26 to 50 metres; show streets (?), over 50 metres.

"The town of Wiesbaden is divided into seven building areas. The distribution of buildings on the various areas is as follows:—

"A. In the three thickly-built building areas.—For the purpose of computing the amount of ground available for building, the building surface is divided into three zones. Zone 1, six metres parallel to the boundary line; zone 2, 26 metres parallel to zone 1; zone 3, the remainder of the building surface. The front garden is not included. Building is allowed as follows:—On building area No. 1 (thickly covered), zone 1, 100 per cent; zone 2, 60 per cent.; zone 3, 50 per cent. On building area No. 2 (moderately covered), zone 1, 100 per cent.; zone 2, 55 per cent.; zone 3, 40 per cent. On building area No. 3 (sparsely covered), zone 1, 100 per cent.; zone 2, 40 per cent.; zone 3, 30 per cent. The height of the buildings is equal to the breadth of the streets, but must be at least 11.00 metres. The buildings must not be higher than 19.00 metres in areas 1 and 2, and 15.00 metres in area 3, and may contain, in areas 1 and 2, not more than four, in area 3, not more than three habitable storeys. The height of each storey must be at least 3.00 metres.

"B. In the four open building areas (villa areas).—The whole building surface, inclusive of the front garden, is included in the computation. The height of the buildings is independent of the breadth of the streets. Building is allowed as follows:—Building area No. 4 (block buildings).—Not more than 40 per cent of the building plot and not more than 6.00 cubic metres of enclosed space to each q.m. of building plot. Distance of buildings from the boundary line of each plot at least 3.00 metres. Height of buildings not more than two and a half times distance from boundary line, and not more than 15.00 metres. Three habitable storeys exclusive of attics or loft. When different houses are joined in one block, the length of this may not exceed 50.00 metres. No buildings may be erected at the sides or behind. Building area No. 5 (fairly open), 3.33 per cent., 3.5 cubic metres. Distance of boundary line 4.00 metres. Height of buildings double this distance, not more than 15.00 metres. Three habitable storeys exclusive of attics or loft. Semi-detached houses and side buildings permitted. Building area No. 6 (moderately open), 25 per cent., 3.00 cubic metres. Distance of boundary line 5.00 metres. Height of buildings one and three-quarter times this distance, at most 15.00 metres. Three habitable storeys, exclusive of attics or loft. Semi-detached houses and side buildings permitted. Building area No. 7 (wide open), 20 per cent., 2.5 cubic metres. Distance of boundary line 5.00 metres. Height of house one and three-quarter times the distance, at most 19.00 metres, in three habitable storeys, exclusive of attics and loft. Semi-detached houses and side buildings permitted."

The party were afterwards driven to see the town planning features. Here again they saw miles of magnificent streets, all trees planted and laid out with the view of subsequent development. Every effort has been made by the municipality to preserve all possible amenities to their town, and large sums of money have been spent in its development, the Kurhaus alone costing about 300,000*l*.

As Professor Eberstadt is not altogether in agreement with the German system of housing the people, it may be interesting to point out that he is opposed to the tenement system, and much prefers the single house system of this country. He expressed the opinion that nothing costs a nation so much as the building of bad houses. Later on, Professor Eberstadt, in response to a request made by the party, delivered the following address and criticism upon the German town plan system:—

"Town planning, let me first say, like many other institutions of our country, is not native to Germany, but has been imported from France. I could trace in France instances of town planning in the sixteenth century. We find a cer-

Digitized by Google

tain building policy in Paris under Henry II., and a deliberate town extension under Henry IV. This French system of building towns and quarters was adopted by our German States in the seventeenth century, and has done marvels in our country. States and provinces which had been ransacked, burnt, and destroyed during the Thirty Years' War were awakened to life again, had population, industry, and towns restored, and if in this country you can discover no trace of the pillaging and the devastation that some of our neighbours have inflicted upon us, it is owing—some old castles excepted—to the town building policy of the State absolutely.

"This is the source of our competence in town building. For the nineteenth century the administration of town building was partly handed over to the self-governing bodies. The immediate supervision of building was reserved to the police, while the most weighty competence of town planning passed to our municipal self-government. They had to execute.

"It is said, 'You carried out your town planning, but you have done it by destroying home.' This, indeed, is the price we have paid for it. Why, we must ask, was it done in this way? Why did it come to this? A development which took fifteen years to investigate you will not expect me to explain to you in fifteen minutes. All I can do is to separate, to pick out a few features, and give you my opinion with reference to these rough items. I shall, then, just dwell upon one singularity. It is the training of our technical staff and the views on town building at the beginning of the new period of municipal development. The new rise in our modern towns began in Germany—twenty years later than in England—about 1860. One of the reasons why our towns were built in the manner which you see now is that our architects and officials were trained to the old tradition of town building. What this old tradition meant, and what should have been done in its place, I may explain in the shortest way by comparing the two systems, the requirements of old and modern town building.

"The first contrast between the old and the new is the inversion in the importance of the centre and the outskirt. In our old system the centre of the town is the best and most desirable residential district; the outskirts are for the lower and poorer class. In the modern town the centre is no more a residential district, and the outskirts are the most important part of town development. The old town system was centripetal, the modern one is centrifugal. A perfect rupture with the old system should have been necessary, as has indeed been effected in England. For our country the system of cutting up the land and guiding the streets that was traditional, and all right for the central parts, was preserved and adopted for the town extension.

"The second contrast is, and should be, the town of the preceding period was a town of burghers, tradespeople, craftsmen, with a certain mixture of small or poor people. The town of our days is a workmen's town—perhaps you may say a town of proletarians; at any rate, 92 per cent. in our country are wage-earners who want the small dwelling, and 8 per cent. only belong to the upper classes. The small dwelling should be the prominent feature of our modern towns. The structure of the population is altogether altered.

"The third contrast is, up to the beginning — in our country to the middle—of the last century our men of business used to reside in the house where their trade was carried on. In the modern town the upper classes live in residential districts, and the bulk of the people—the working people—naturally never knew it otherwise. The modern town has to provide for purely residential districts. So the new town had quite new requirements to meet. But none of these three great problems has been solved, not even faced, in our country. We have merely preserved the old system, enlarged it, and exaggerated it; and this is one of the reasons why a competence good and useful in itself, beneficial in former days, has not proved a success with us.

"Town building or constructing may be divided into three sets of competences in our country—town planning, by-laws with reference to buildings, and real credit for procuring capital. As for town planning, you now know our system, which is broad streets and expensive methods of paving. This is the starting-point; the first of the premises which follow each other without mercy to the conclusion. It means—according to our system—expensive streets for the ground owner, dearness of the land, accumulation of tenements, high-storeyed buildings and courtyard dwellings. Our town extension is handicapped by a powerful speculation, and is altogether defective.

"To avoid some of the mistakes in our town-planning, I advocate the construction of streets into traffic streets and residential streets; but I should rather call them non-traffic streets, because the most prominent feature would be to exclude traffic. It is hardly possible to give you an idea of the effect, and, I might say, of the fitness and the beauty of the non-traffic street. The old towns knew these streets and I have gathered some examples, reproduced in my handbook, 'Augsburg, Ulm, Danzig.' The by-laws must be made to conform with town planning This has been again mixed in most cases in our country. You are aware that our by-laws have the constructions by zones and districts. It is the most lovely domain of red-tapeism. There routine and uniformity, ordering about and giving directions, attain their highest triumph. But even if it be moderately done it is not always well done.

"We come now to a competence somewhat similar to what you call limiting the number of houses per acre. We limit, as you know, the percentage of area that may be built upon and the number of storeys. I think it is a mistake to single out absolutely certain districts and give rules of uniformity for them. There is nothing absolute in town building; you must observe and give in everywhere. The right principle to me seems to be inter-crossing of streets according to their use and construction.

"The great problem now is to keep down and regulate prices of land. Beyond doubt, there is a danger that town planning may act as a pacemaker for land speculation. For town planning does not change agricultural land into high-priced building ground, but at least it gives the expectation for this change. It says to the speculator, 'I show you the land where you may invest.'

"I do not think there is much to be feared if three things are provided:—1. Traffic streets and means of transport must first be made and precede the development of the land. 2. The type of house which is the most convenient for private enterprise and building trade must be preserved and protected in town planning and in by-laws. 3. Make it as safe and as profitable as you can to employ private capital in productive enterprise and production of houses, and make it as unsafe and unprofitable to invest in land speculation. A low ground-rent, a high income for personal activity and enterprise, that is what you are to aim at."

THE ELECTROLYTIC THEORY OF THE CORROSION OF IRON.*

(Concluded from last week.)

SINCE the presence of the polarising film of hydrogen arrests the further solution of the iron, it is obvious that in order for the reaction to proceed this hydrogen must be removed. The destruction of the hydrogen film in ordinary corrosion is accomplished by the oxygen of the atmosphere, which is dissolved in the water. The action here taking place is a simple union of the hydrogen on the iron and the oxygen dissolved from the air, with the re-formation of water. It follows from this that any substance which dissolves or reacts with hydrogen should accelerate corrosion. This is found to be in fact the case.

It was formerly thought that the action of oxygen as a factor necessary in corrosion was simply to oxidise the iron ions thrown into solution, and to precipitate them as rust. While it is true that this reaction does take place, and is indeed the most striking function that oxygen performs, it is in reality a secondary one, which is simply incidental to corrosion and not a necessary part of the action. Its real accelerating effect is due to the fact that it depolarises the hydrogen which is set free by the reaction, and separates out on the metallic iron.

That this is true may be seen from the consideration of a number of now well-known phenomena. When a piece of iron is placed in ordinary water exposed to the air it will dissolve or rust. If now there be placed in the water with this piece of iron a piece of platinum, the solvent or corroding action of the water will not be changed. The oxygen is present in the solution as before, and the iron ions as they separate from the metallic iron are being oxidised and precipitated as rust. If now the platinum and iron be electrically connected, a marked increase in the rate of the solution or corrosion of the iron is noticed. No chemical condition has been changed; the difference lies in the fact that there is now an electrical contact between the iron and the platinum, and the platinum furnishes a surface on which the hydrogen can deposit, and on which, by virtue of its catalysing action, the hydrogen will be rapidly oxidised by the dissolved oxygen and thus removed from the sphere of action.

* From a paper presented to the Iron and Steel Institute by William H. Walker, Boston, U.S.A.

Digitized by Google

Or if in two limbs of a U-tube separated at the bottom by a jelly plug there be placed two pieces of the same iron, electrically connected, and in a very dilute solution of any electrolyte, and both of these limbs be protected from the air, no action will be noticed. That is, there will be on both pieces of iron points at which iron has gone or tends to go into solution, and points at which a film of hydrogen has deposited, and owing to the resistance of this film of hydrogen no local currents can pass over the surface of the pieces of iron, and no current as a whole passes through the jelly plug at the bottom, or through the system as a whole. If now there be placed in one of the limbs a substance which will unite with hydrogen, such as potassium bichromate or alkaline hydroxylamine, still no action will be observed in that limb, but the iron in the other limb will pass into solution and a current of electricity will pass through the system.

A third example is found in the action of zinc in water containing an electrolyte. If a strip of zinc and a piece of iron be placed in water containing a very little salt, the iron will corrode rapidly, while the zinc will be but slightly attacked. The usual explanation for this phenomenon is that the zinc protects itself with an adherent film of zinc oxide or hydroxide, while the iron produces a non-adherent voluminous hydroxide which does not protect. If now instead of being separated the two strips of metal be placed so as to touch each other, the iron no longer corrodes, but the zinc rapidly passes into solution. A piece of zinc is seen at the centre, corroding slightly from the ends, and showing the red due to the separating hydrogen ions at the centre. Zinc ferricyanide is white, and hence the same reagent demonstrates the separation of zinc ions just as it does the iron ions in the plate already considered. The nail which has been connected to another piece of zinc is not corroding, but is protected by the separating hydrogen. The zinc thus connected, however, is seen to be rapidly dissolving. The presence of the iron cannot affect the nature of the coating of zinc hydroxide which in the previous case adhered thereto and protected, according to the old explanation, the sheet of zinc, nor can the presence of the zinc affect the oxidation and precipitation of the iron ions should they pass into solution as they are wont to do. The explanation consistent with the electrolytic theory is that the zinc in the first arrangement does not dissolve and corrode, not because there was formed an adherent and protecting layer of zinc hydroxide, but because the surface of the zinc does not catalyse the reaction $H_2+O=H_2O$ with sufficient rapidity to continually remove the hydrogen from the surface of the zinc. The film of hydrogen, therefore, forms on the zinc and protects it. Although the catalysing action of the iron surface is not so rapid as is the platinum surface, it has sufficient rapidity to depolarise the iron strip and to render continuous the solution, and therefore the corrosion of the iron. While the solution pressure, that is, the tendency to pass into solution, is much stronger in the case of the zinc than it is in the iron, the iron corrodes and the zinc does not, because the electrolytic double layer set up on the surface of the zinc cannot rapidly be destroyed by a flow of electric current. When the two are united, the greater solution pressure of the zinc forces a large number of zinc ions into the solution, and the next result of the flow of the current is that the zinc soon becomes anodic over its entire surface, while the iron becomes the cathode, and that no iron is then dissolved, but as a cathode furnishes a surface on which the hydrogen, set free by the solution of the zinc, may be deposited and catalysed and removed.

Having now a conception of the mechanism by which iron corrodes, some important conclusions may be drawn from a consideration of the factors involved. Since before the iron can form rust it must first pass into solution, and in so doing cause an electric current to flow from the iron at that point to the iron at some other point, any circumstance which will aid the flow of this current will accelerate the solution of the iron. In other words, any differences in potential which may exist upon the surface of the iron will in itself cause a flow of electricity which will result in a solvent action on the iron. Such differences of potential inevitably result from a segregation or uneven distribution of any impurities which the iron or steel may contain. Hence we should expect that the speed of corrosion would increase in accordance with the percentage of impurities present, and it should decrease in accordance with the care bestowed upon the iron or steel during its manufacture to prevent a segregation of these impurities. The simplest way, of course, to insure an absence of segregation is to eliminate altogether those materials not needed in the iron. It has been found that a steel made under such conditions that the total impurities are reduced to not over five hundredths of 1 per cent. (0.05 per cent.) resists corrosion to an extent equal to the iron of our forefathers. The steel companies have been slow to accept this general proposition, but it is gratifying to know that material of this purity may now be obtained on the open market.

Since iron can pass into solution only by assuming the ionic form, and having at the same time an equivalent amount of hydrogen pass from the ionic condition to the gaseous state, the speed of the reaction will depend upon the number of hydrogen ions present in the solution. The effect of free acids has already been noted; but the presence of any material, such as alum or magnesium chloride when subjected to pressure, or other materials which by hydrolysis will form an acid, will also accelerate corrosion.

If, on the other hand, the hydrogen concentration be reduced, the corrosion of the iron will also be decreased. Such a condition may be most easily realised by adding to the water a strong alkali, which, owing to the presence of a large number of hydroxyl ions, decreases thereby the number of the hydrogen ions. This is the probable explanation why the iron of Dr. Friend's experiment did not corrode in the presence of oxygen and hydrogen. It has been shown by conductivity experiments that it is impossible to remove all the caustic soda from iron and glass by a few rinsings. It is worthy of note that the only time when the iron was not soaked in caustic soda it rusted, notwithstanding the absence of any carbonic acid.

This fact has an important bearing upon the question which has lately been much discussed, as to whether concrete will protect iron from corrosion. Inasmuch as Portland cement, when it sets or hardens, liberates a large quantity of caustic lime, which is a strong alkali, and since good concrete is therefore saturated with this strong alkali, the answer to the question must be in the affirmative. Iron or steel will not corrode when embedded in concrete. But caustic lime is soluble in water, and poorly made concrete is not impervious to water. Therefore, if iron be embedded in concrete through which water at any time be allowed to percolate, this calcium hydrate will be slowly but surely dissolved and washed away, and with it will disappear the inhibiting action of the concrete, and iron embedded therein will surely rust. To insure absolute protection of the reinforcing members of concrete construction, therefore, such concrete must be sufficiently dense and carefully made to render it practically waterproof. This is not an impossible condition.

The fact that the presence of a metallic iron surface accelerates the corrosion of zinc has an important bearing upon the protection of such structure as barbed wire fencing, or any structure where both an iron and zinc surface are exposed. In making barbed wire fencing, for example, the wire is first galvanised and then wound into fencing, the cross wires forming the barbs being cut at an angle in order to make a pointed barb. This freshly cut surface of iron is thus exposed, and so furnishes just the surface required for depolarising the zinc surface, and thus greatly increases the rapidity with which the zinc coating will corrode. As the zinc coating recedes from the iron surface, the latter rusts on account of the low conductivity of the water film on the two, and hence the explanation of why deterioration of a barbed wire fence always starts at the barbs and travels from there along the strands. It also shows the necessity of protecting those places on a galvanised structure from which the zinc, from whatever cause, has been removed.

Since oxygen is necessary to insure the continuous removal of the hydrogen film, it is obvious that if no oxygen be allowed to reach the iron through the water, no corrosion can take place. This fact teaches us much regarding the corrosion of boiler shells and tubes. Pitting may be entirely avoided if the air be removed from the feed water before its introduction into the boiler. This may be best done by the employment of an open feed water heater, or, what is better still, a feed water heater connected to the dry vacuum pumps of the condenser. If such treatment is not possible, the air may be removed from the feed water by drawing the water through a closed box containing scrap iron; the oxygen in the water is used up in corroding the scrap iron instead of the boiler tubes. Or the oxygen in the water may be absorbed by feeding into the boiler with the water a very small quantity of an alkaline solution of a tannin material. Such a solution of alkaline tannate will break up under the pressure and temperature of the boiler, with a formation of a pyrogallate of the alkali, and this rapidly absorbs the oxygen. Soda ash, or rather alkali, is of course useful, but not because of its effect upon the oxygen content, but because,

Digitized by Google

as has already been explained, corrosion is inhibited by thus decreasing the hydrogen ion concentration of the water.

Tin is a metal which, like copper, accelerates the corrosion of iron by aiding in the oxidation of the hydrogen set free by the reaction. If, therefore, in the manufacture of the so-called tinplate, which is sheet iron or steel covered with a layer of metallic tin, there be imperfections or pinholes in the tin coating, these channels through the tin to the iron will become centres of corrosion which rapidly destroy the plate. It is impossible to detect these imperfections by a simple inspection, and hence users of tinplate have been unable to test the quality of their raw material from this point of view. Since the iron must pass into solution at these exposed points in the tin coating, their presence may be easily located by flowing upon the tin surface a solution of gelatine or glue in which is dissolved some potassium ferricyanide. When the jelly has stiffened the iron will pass into solution through the holes in the tin and, reacting with the ferricyanide, will leave a bright blue spot in the jelly. Variations in the quality of tinplate may thus be easily detected.

The author has already shown* that "mill scale" or magnetic oxide of iron is strongly electro-negative to iron. Since mill scale is insoluble in water and cannot of itself enter into the reaction, its only function must be analogous to that of platinum or other insoluble conductor of this kind, viz., to furnish a surface on which the hydrogen liberated by the dissolving iron can separate and be catalytically oxidised to water again. This is also true of the black oxide protective coatings sometimes used upon iron and steel, as, for example, that of the Bower-Barff process. Just as is the case in mill scale, these coatings are very serviceable so long as the whole coating is intact. But so soon as a portion of the metallic iron is exposed, this portion corrodes all the more rapidly on account of the presence of the surface of scale on which the oxidation of the hydrogen and consequent depolarisation can go on.

Many more examples of the application of the electrolytic theory to problems of corrosion could be given, but these will suffice to make clear the general applicability of the theory, and its usefulness in the investigation of a subject of such fundamental importance to manufacturers and users of iron and steel.

THE NATIONAL PORTRAIT GALLERY.

THE Trustees of the National Portrait Gallery in their fifty-second annual report state they are glad to be able to report that arrangements have been made with them by the First Commissioner of His Majesty's Works whereby a piece of land to the west of the Gallery, forming part of the site at present occupied by St. George's Barracks, has been definitely allotted to an extension of the National Portrait Gallery, as soon as the site shall have been vacated by the military authorities and the buildings at present occupying the site removed.

The Trustees look forward eagerly to this long-needed extension of the National Portrait Gallery, and express their hope that in the actual disposition of the site in question between this Gallery and the National Gallery an opportunity may arise for the simplification of certain complications in the construction of the National Portrait Gallery which at present give rise to unnecessary trouble and expense.

The list of 817 donations, loans, or bequests, as given in the former reports, may now be continued up to 835. Among them are Frederick Walker, A.R.A. (1840-75), painted in water-colours by himself; William Makepeace Thackeray (1811-63), a plaster cast from a mould of his face and right hand taken after death by Messrs. D. Brucciani & Co., and by whom it is presented; Benjamin Robert Haydon (1786-1846), the historical painter, drawn in pencil by Sir David Wilkie, R.A.; Sir Thomas Lawrence, P.R.A. (1769-1830), a bronze cast by S. Parker, after a medallion by E. H. Baily; Sir John Everett Millais, P.R.A. (1829-96), a plaster cast from a statuette modelled in 1863 by Sir J. E. Boehm, R.A.; and Dante Gabriel Rossetti (1828-82), a facsimile reproduction of a drawing by Simeon Solomon.

The number of purchases now amounts to 758. The twenty bought during the past year include a pencil sketch of Alfred Stevens made by himself when a student at Rome, and a painting of Matthew Boulton, F.R.S. (1728-1809), the eminent engineer and founder of the famous Soho Works at Birmingham, 1762, and who as partner of James Watt completed with him the invention of the steam-engine as an instrument of practical utility.

The number of portraits now on the register in the collection is 1,536, exclusive of engravings, photographs and other portraits of a supplementary nature, which bring the total number of portraits actually exhibited to 1,734.

In response to what was evidently a demand on the part of the public, the Trustees of the National Portrait Gallery say they have willingly agreed to a proposal that the Gallery should be opened to the public on Sunday afternoons throughout the year. At the same time the Trustees desire to record their opinion that in the absence of any artificial light in the Galleries the amount of light for the inspection of pictures and works of art on winter afternoons is very scanty, and hardly seems to justify the expense of opening the Gallery. The Trustees have communicated to His Majesty's Treasury their willingness that artificial light should be introduced into the exhibition galleries, but have received an unfavourable reply.

Owing to lack of funds for the payment of the staff, the Trustees were unable to open the National Portrait Gallery on Sunday afternoons from November 1908 to March 1909 inclusive. The Gallery will, however, in future, be opened to the public on Sunday afternoons throughout the year at the following hours:—January, February, November, December (light permitting), 2 P.M. to 4 P.M.; March to October, 2.30 P.M. to 5.30 P.M.

The total number of visitors admitted on Sunday afternoons during the summer of 1908 (April to October) was 13,306, giving an average of 443 per Sunday.

The number of visitors admitted to the National Portrait Gallery during the year 1908 amounted to 164,981. The total is made up as follows:—Visitors admitted free of charge on week days, 141,006; visitors admitted on payment of 6*d*., 10,669; visitors admitted on Sunday afternoons, 13,306.

For the three months January 1 to March 31, 1909, the total number of visitors was 26,909, of which number 1,495 were admitted on payment of 6*d*.

The total number of visitors admitted to the National Portrait Gallery since the opening of the new building in St. Martin's Place on April 4, 1896, to March 31, 1909, is 1,824,913.

THE LAYING OUT OF NEW STREETS.*

THERE has been much controversy as to whether the erection of buildings at the side of an existing road amounts to the laying out of a new street within the meaning of the by-laws usually in force in both rural and urban districts. All the cases which have been before the courts seem to lay it down that it is possible for an old highway to become a new street, but no rule is laid down to clearly define when such highway does in fact become a "new street," and the controversy cannot or will not be determined until fresh legislation definitely settles the point for us. All we can get from the decisions is, that the question is purely one of fact whether the building owner who is building on land abutting on a highway is making or laying out a new street. The decisions up to 1900 are clearly discussed in a leading article in Vol. 64 of the "Justice of the Peace," pp. 577 and 593. The Devonport case ("Devonport Corporation *v.* Tozer," 1903), some writers appear to think, has overthrown the doctrine that when a building owner erects houses by the side of an old lane he may be held to be laying out a new street, whilst others are of opinion that the question is one of fact for the Justices to determine in every particular case, a position of affairs which cannot be considered satisfactory by any means as the views and decisions of magistrates may be as widely different as the poles, especially where landowners constitute the majority of the bench.

It must not be forgotten by local authorities, if they take proceedings before Justices, that it may possibly be held that the road which the local authority declares to be a "new street" is already a "street." The precise moment therefore when a highway becomes a "new street" is most difficult to determine, and it is too much to hope for or expect a bench of county magistrates to see eye to eye with a local authority in this class of case.

The object of this short paper is to draw the attention of the Conference to a case in which the Leigh Rural District Council has recently been involved (simply as an illustration of what local authorities have to contend with and to make

* A paper read by Mr. E. Williams, clerk to the Leigh Rural District Council, at the annual conference of the Rural District Councils' Association last week.

Digitized by Google

clear the point I am raising), and to ask the Association to support the following resolution submitted by my Council and adopted by the Parliamentary Committee of the Executive Council of the Rural District Councils' Association:—

Resolution:—

"Resolved, on the motion of Mr. Battersby, seconded by Mr. Prescott, that the Local Government Board be urged to immediately promote legislation which shall provide that in all cases where a landowner lays out land for building purposes abutting on an existing highway, the local authority may require such highway to be widened by the landowner to the width prescribed by the bye-laws of such authority for new streets and buildings."

The facts of the Leigh Rural District Council v. B. case are as follows:—

On December 7, 1907, B. submitted to the Council's surveyor draft plans of a house and shop he intended to build on an existing highway. He was informed by the surveyor before complete plans were submitted that the Council would require him to add a strip of land fronting his proposed buildings to the highway, so as to provide for a 36-feet street in accordance with the Council's bye-laws. The surveyor had informed B. that in consequence of the number of buildings which had been erected on the opposite side of the road to the proposed premises (about forty in number), the Council would deem the lane or highway to be a "new street." This was a wise step to take, as B.'s was the first house to be built on the west side of the lane. B. submitted complete plans to the Council, with the following note endorsed thereon:—

"Note.—The new street line to be 18 feet from the present centre of X—— Lane as shown on plan, and marked proposed new fence line. The strip coloured brown between the present and proposed lines to be given to the roadway so as to provide for the half of a 36-feet street as required by the bye-laws."

The Council approved the plans, and B. erected his house and shop, but when he erected his fence wall he ignored the arrangement made with the Council and built the fence wall upon the old line of fence and enclosed the strip coloured brown. Proceedings were taken against B. for contravening the Council's bye-laws by erecting the "building" without depositing a plan showing the position of the wall, and contravening the bye-laws as to new streets. The case was partly heard by the Justices when a compromise was agreed upon on the following terms:—The Council to pay B. 5*l.* towards his costs (which must have been very considerable), and to rebuild his wall (which cost the Council 6*l.*) on the new fence line; B. to give the land coloured brown, and to admit that he was laying out a new street.

Thus ended a case which might have involved both parties in heavy costs. Similar cases will undoubtedly crop up again and again, and it is advisable that local authorities should bestir themselves to see that legislation is promoted to obviate the difficulties above referred to.

My Council have raised the question as to whether a bye-law could not be framed under Section 157 of the Public Health Act, 1875, to meet such cases, but the Local Government Board in a letter dated October 1, 1908, state "that it is beyond the scope of the bye-laws to determine when an existing highway becomes a new street. This would be a question of fact to be decided by the Justices according to the circumstances of each case." From this it would appear that until the legislature deals with the point, local authorities must fight each case on its merits, and probably spend large sums before they get a decision. Why a landowner should be compelled to make an entirely new street 36 feet wide and yet be allowed to build along an existing highway without any question being raised as to the width of the road, passes all understanding, and is quite unreasonable. It is absolutely essential that we should have wide roads to cope with the ever-increasing motor and other traffic, and it is for local authorities to see that roads in their districts are not crippled in width by landowners erecting or permitting buildings to be erected along existing fence lines in narrow lanes. Why should they not be compelled to widen a highway to a width prescribed by a bye-law? The condition of our roads has been considerably improved at the expense of the ratepayers, and the value of land abutting on them has been greatly enhanced for building purposes, yet local authorities, if they desire to widen an existing highway, must pay a "building land price" for the land they require to carry out such widening. Why should not the betterment system be adopted in such cases, or at the least the requisite land for widening the highway be given up by the landowner?

The question now is what shall local authorities do under existing conditions.

There appear to be only two ways in which to act: the first way is, to ask the building owner to convey to the Council the land required for widening to the roadway, before approving his plans of new buildings; and the second is, if he declines to convey the land, to refuse, on the authority of "Smith v. Chorley Rural District Council," to pass or sanction his plans and let him take whatever proceedings he may think fit.

If the building owner decides to erect buildings without the approval of his plans, the Council's remedy will be to take proceedings for the enforcement of the bye-law alleged to have been infringed. This line of action will in most instances restrain the building owner from proceeding with his building, and the landowner, who is the real sinner, will come to terms with the local authority.

It is a wise (and reasonable) plan to give notice to landowners when the local authority consider an existing highway in their district is taking the form of a new street. Much trouble and possibly litigation may be avoided thereby. Such, at any rate, is my experience.

The following is an extract from a private Act:—

"29. (1) When a road or lane within the borough becomes in consequence of building operations a new street within the meaning of the Public Health Act, 1875, but the land on only one side of such street has been or is in course of being built on, the Corporation may, instead of requiring the owner of the land built on, or in course of being built on, to widen such road or lane to a width prescribed by the bye-laws in force in the borough, require such owner to widen such road or lane so as to give a width not less than one-half of such prescribed width from the old centre line of such road or lane to the boundary thereof adjoining such land.

"(2) Provided that if and when the land on the opposite side of such road or lane shall be built on the Corporation shall require the owner of such land to complete the widening of such road or lane so as to give the complete width prescribed by the bye-laws of the Corporation."

It will be seen that some attempt has been made by a Corporation to ensure the widening of existing highways, but the all-important question under this clause is, "When does a road or lane become, in consequence of building operations, a new street?" Even this Corporation, with its Private Act, is precious little nearer the real root of the trouble than rural district councils are, and I submit it is only right and just that local authorities should themselves have the power to say that a road or lane shall be widened by the landowner to the width required by the bye-laws whenever he builds or lets land for building purposes along such road or lane.

It also seems desirable that County Councils should be empowered to make bye-laws with respect to the width of main and secondary roads where building operations are contemplated, so as to ensure that such roads are constructed of a uniform width, in view of the fact that the requirements as to the width of new streets under the bye-laws of various local authorities differ, and that even in adjoining districts.

I propose the resolution submitted by my Council to the Association.

GAS HEATING RESEARCH.*

Introduction.

WHEN coal gas is burned in an enclosed space, the amount of heat † communicated to that space depends only on the chemical composition of the gas and the amount of it that is burned, provided that in the end it is burned completely to carbon dioxide and water. No mechanical contrivance can increase the total output of heat.

If we suppose the gas to be burned in a naked flame, the heat is delivered to the surrounding space in three ways. In the first place, the hot products of combustion stream upwards, intermingling with the air, warming it and any surfaces with which they come in contact. In the second place, a certain amount of air is warmed by contact with the flame; and this also carries away heat. Heat distributed by hot currents of gases is said to be convected. In the third place, the flame parts with some of its heat by emitting rays through the air in every direction on to the

* Extract from report of the Gas Heating Research Committee appointed by the Institution of Gas Engineers in conjunction with the University of Leeds, and consisting of Messrs. John Bond, J. H. Brearley, and Charles Wood, in co-operation with Professors Arthur Smithells (Chairman), William A. Bone, and Julius B. Cohen, of the University of Leeds, and Mr. E. W. Smith (Research Chemist), to the Institution of Gas Engineers, at their Annual Meeting held in London during June 1909.

† To ensure clearness the word "heat" is used here, although it would be more scientifically accurate to substitute "energy."

Digitized by Google

objects in the room. Heat distributed in this way is said to be radiated.

If the utility of an appliance for heating by gas depended solely on the amount of heat that was given out, a simple burner giving a naked flame, whether luminous or atmospheric, would be as effective as any other appliance. But the utility of a gas-heating appliance such as a gas-stove must be considered in regard to a number of practical questions:—

1. If, for example, we desire not to introduce the products of combustion into the space we are heating, we must provide the stove with a flue sufficiently large to carry off these products. The flue may be so arranged as to its length and the conductivity of its material that it will drain off most of the heat of the gases passing through; so that if the flue, before opening into the outside air, is wound about inside the space that is being heated, the products of combustion may be got rid of without taking much heat with them.

2. Again, we may desire to avoid very hot currents of air, which rise at once to the ceiling; and in that case, instead of using a naked flame, we should cause it and its products to heat up metallic surfaces of some considerable extent. These heated surfaces would then cause much cooler and broader and more slowly moving upward currents of air, which would set up a more general circulation in the room.

3. We might desire to obtain as much heat as possible in the form of radiant energy sensible as heat. In that case we should cause the flame and its products to heat up some material of such a kind and in such a way that it drained a very large quantity of heat from the flame and emitted it again in the form of radiation.

4. Lastly, it may be supposed that a gas-stove is desired not only to heat, but to ventilate, a room. In that case it will have to be so used as to eject air in addition to its own products of combustion.

Other considerations might be named, but these are sufficient to emphasise the chief points that have to be considered in regard to the heating efficiency of gas-stoves. And gas-stoves might be relegated to one or other of three categories according as they heated a room mainly: (1) by direct diffusion of hot products of combustion, (2) by heating surfaces which caused convection currents of warm air, (3) by radiation. Stoves of the first type are to be found in the "reflecting stoves," which are not infrequently used to take the chill off the air of shops. Stoves of the second type include "radiators," "steam radiators," and "condensing" stoves. The use, or rather the misuse, of the word "radiator" in this connection is based on a similar misuse which has become common in connection with steam or hot-water heating coils. These appliances would be more correctly called "convectors," as their heat is almost entirely delivered by warming the surrounding air and so causing convection currents. Stoves of the third type include the normal gas-stove, where atmospheric flames are caused to heat up a refractory fuel to the highest possible temperature. Of course there are stoves of intermediate type, in which more than one of these methods plays an important part.

There can be no doubt that the form of heating most acceptable to the Englishman in a living room is radiation from a bright fire, and it is in the comparison of the brightness and radiant warmth of coal-fires and gas-fires that gas-fires (apart from questions of cost) are commonly disparaged. There is also a very widespread and deeply rooted belief that a gas-fire, even if satisfactory as a radiator, is necessarily attended by some hygienic disadvantage.

In taking up the study of gas-heating appliances and endeavouring to gain an accurate estimate of their efficiency, the Committee felt that they might best begin with a study of the radiating efficiency of gas-stoves, including, incidentally, a study of the hygienic conditions. If the radiating efficiency of gas-stoves can be materially improved, and if it can be shown that a gas-stove, when properly constructed and used, has no more deleterious influence than a coal-fire, a great advance will have been made towards the substitution of gaseous for solid fuel as a means of domestic heating. In the following report will be found details of the measurements of radiation from one of the prevailing types of gas-stove with fire-clay fuël. These measurements, it is believed, have been made with as much accuracy as is at present possible, and give for the first time a tolerably correct absolute measurement of the radiating power of a gas-stove.

Open Gas Fires, by E. W. SMITH, M.Sc.

This included the determination of:—(*a*) The total energy radiated as heat from the stove. (*b*) The effect on the radiation of changes in the volume of air passing through the room and up the flue. (*c*) The extent of the so-called "drying" of the room air where open gas-fires are used. (*d*) The extent of the vitiation of the room air caused by open gas-fires. (*e*) The amount of heat passing directly up the flue and not available for heating the room. (*f*) The amount of carbon dioxide found (1) in the room and (2) in the flue. (*g*) The amount of heat used in heating the air of the room. (*h*) The volume of air that might be raised from 45 degs. to 60 degs. Fahr. by the heat available in the stove. (*i*) The effect of using a reflector. (*j*) The effect on the heat lost to the room, of changes in the volume of air passing up the flue.

Description of the Experimenting Room.—It was very necessary in connection with this work that the varying conditions to be coped with should be completely under control. For this purpose a special chamber was built in one of the rooms of Woodhouse Lodge—a building adjacent to the Fuel Department of the University of Leeds. It consisted of a double-walled room built of tongued and grooved boards, the inner and outer walls being about 2½ inches apart. These were made as nearly as possible air-tight by lining the inside walls with calico, coated with asbestos paint, and the outside walls with a thin coating of pitch. The floor, which had to bear the weight of the stoves, &c., consisted of a layer of tongued and grooved boards made air-tight with painted calico. Over these asbestos board was laid, and on the top of this a sheet of asbestos-magnesia cement.

(*To be continued.*)

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *American Architect* continues its illustrations of the architecture of the Southern States with examples of schools at Atlanta, Georgia and Manning, South Carolina. It also contains a number of specimens of students' designs for the Society of Beaux-Arts architects.

La Construction Moderne illustrates a modern French country house, Cashel Bénerville, near Deauville, Calvados, a stone and half-timber house, with steep-pitched hipped and dormered tiled roofs. The architect is M. H. Goury. We may be prejudiced, but we prefer the country houses of our own native architects.

Deutsche Bauzeitung illustrates and describes the new Catholic parish church at Spandau, of which Professor Christoph Hehl of Charlottenburg is the architect, which both in plan and detail is based upon the national German Romanesque or round-arched Gothic. The chief feature of the plan is the decagonal central area surmounted by a dome, and from which project apses, transepts and short nave.

Dekorative Kunst illustrates a country house at Kruman, of which Herr Victor Kafka, of Prague, is the architect, which has some attractive points in its planning and grouping, and is treated with charming simplicity in its internal detail. A special feature of this issue is the work of two ladies, Clara Paster and Marie Sturm, in necklaces of old Venetian glass beads.

The *Engineering Record* (New York) is chiefly occupied with the proceedings of the American Waterworks Association, abstracts being given of papers read at the recent Milwaukee Convention of that body.

COMPETITION RESULTS.

THE successful architects in the competitions held for the two new schools about to be erected by Govan School Board, N.B., are:—For Hyndland School, Mr. H. E. Clifford, and for the Craigton School, Messrs. Watson & Salmond. The architects to whom premiums have been awarded are:—For the Hyndland School, Messrs. J. Thomson & R. D. Sandilands, Mr. William B. Whitie, and Mr. Alexander N. Knox; and for the Craigton School, Mr. H. E. Clifford, Mr. John Hamilton, and Mr. J. Gibb Morton.

NOTABILIA.

THE *Connoisseur* continues the account of the City and County of York, by Leonard Willoughby, the history of the city being sketched and various treasures of the Minster and the Mansion House being illustrated. An interesting feature is the series of illustrations of the Corporation plate of the city of York. Haldane Macfall continues the account of early Georgian furniture of "the years of mahogany."

The *Burlington Magazine* has a finely illustrated article showing some very remarkable examples of goldsmiths' work from the collection of drinking horns and silver plate in the National Museum at Copenhagen.

Digitized by Google

The *Art Journal* continues the series of articles by R. Ll. B. Rathbone on "The Artistic Training of a Jeweller," in which good principles are illustrated by reference to Anglo-Saxon, Byzantine and ancient Roman work. Kew Gardens and its architecture is described and illustrated by a number of excellent pencil drawings by Edward C. Clifford, R.I.

Correspondence

[The Editor will not be responsible for the opinions expressed by Correspondents.]

Influence of Material.

SIR,—As the idea of applying geometry to architectural design has been for long a vexed question, perhaps you will allow me space for a few remarks in reply to Mr. Percy L. Marks's letter, at least that part of it with which I have to do.

I do not suppose any architect would be so unwise as to found his design solely on a basis of geometry. He may use it as a corrective, but not as a substitute for imagination, which must hold the first place. And this is what I presume the architect of the Parthenon did, first putting his design together out of the accumulated material of his past, allowing refined imagination full play, and then correcting it by the application of geometry. Imagination and reason should work together in determining design. Imagination alone may lead to eccentricity, reason alone to uninspiration.

Mr. Marks states that if other Grecian buildings are examined, different proportions are found, and still they are good architecture. That is quite true. The Erechtheum is outlined by angles of 60° and 30°, and as instances of differently arranged schemes of 45° and 22½° triangulation there are the little temple of Nikè Apteros and the exquisite monument of Lysicrates which is so outlined from finial to base. But these instances do not invalidate my argument about the Parthenon, which, when compared with similar buildings of its style, holds the field for beauty of proportion; and if its architect did not avail himself of any geometrical system of revision, the result of the application as shown in my diagram is a remarkable instance of coincidences.

What special value these angles possess I cannot tell. It is a fact, however, that the equilateral triangle largely determined much Mediæval work, and it is reasonable to suppose that a similar system was employed in Classic work.

An architect cannot run riot in his design and succeed. He must submit to law as other creators of art have to do.

This theory of the part played by geometry is strengthened by the method that was apparently employed to fix the diameters of columns both Classic and Mediæval, as shown in the diagram.

If this also be the result of accident, then here we have another remarkable coincidence which fails to be accounted for.—I am, faithfully yours, G. S. AITKEN.

Edinburgh: July 5, 1909.

"The Arts Connected with Building."

SIR,—I have just noticed your review of "The Arts connected with Building" in to-day's issue of your paper, and desire to thank you for the same. I however hasten to point out that the illustrations were added in the book at the special wish of Mr. Raffles Davison and myself, and this is mentioned in the second paragraph of the third page of Mr. Davison's introductory note. It was generally the wish of the lecturers that their work should not be illustrated, but it seemed to Mr. Davison and me only right that the public should realise that the lecturers had carried into practice the principles they had laid down.—I am, yours faithfully, B. T. BATSFORD.

94 High Holborn, London: July 2, 1909.

Guild of Architects' Assistants.

SIR,—Having reference to the leaderette in your current number *re* the Guild of Architects' Assistants, would you kindly allow me some space to comment upon the same as a member of the Committee of the above Guild?

The article in question starts by asserting that "the Guild of Architects' Assistants is the result rather of the development of the practice of young architects of the present day of spending their whole life as assistants rather than as attempting to make an independent position as principals." In that particular may I point out that the present position of young architects is much more complicated than of former days, say, when our grandfathers were in practice for themselves. Competition in all forms is greater now than then, and together with the increased facilities for a scanty architectural education which enables a poorer class of men to style themselves architects, some of which turn out to be good assistants, and some, where the opportunities occur, if they have the business qualities more strongly marked may find themselves in the position of employing some of their less fortunate colleagues who may or may not be fairly treated, which makes the relation of principal to assistant become more and more acute. Consequently the assistants, realising that their chances of becoming principals are becoming more and more remote, and the possibility of unscrupulous men being able to call themselves architects becoming more and more a fact and a degradation to Art, have seen the necessity of forming a guild for the protection of assistants, and the furtherance of architecture as an art, much in the same manner as principals have felt the necessity of forming institutions to aid them in questions relating to differences that might occur between the architect and his employer, euphemistically called the client.

It is certainly easy to get assistants that will take thirty shillings a week, but there is no doubt that some if properly treated would be worth much more, for many architects fail to get the best out of their assistants by not offering them any hope or interest in their profession. Therefore it is hoped that by the influence of the Guild through the power of combination and the sympathy of practising gentlemen to enrol a superior class who, if they could not practice entirely for themselves, would make good managing assistants.

If the Guild can attain this it will certainly benefit both principal and assistant, and we are told at the end of the leaderette that "they will find that employers will be only too ready to give berths to this class and treat them fairly and generously as permanent members of their staff"; but this assertion does seem a little optimistic, for firstly, we must assume that the architects in question are not going to suffer by the increasing competition so as to interfere with their permanent supply of work, and secondly, that owing to the decreasing competition between assistants that principals will not be able to get good men at a less wage.

It has now become clear that unless a better understanding between principal and assistant is made that the position for both will become worse for the profession at large.

I venture to suggest that when the Guild has become sufficiently felt so as to improve the present educational position of architects, that something in the nature of co-partnership should come to their consideration as a solution to the outcry of those principals who say that they cannot get a good managing assistant worth 5*l.* per week.—I am, yours faithfully, HERBERT COX.

10 Mecklenburgh Street, Mecklenburgh Square, London, W.C.

P.S.—The Secretary of the Guild is E. J. Dixon, Esq., A.R.I.B.A., 60 Idmiston Road, Stratford, London, E.

July 6, 1909.

GENERAL.

The Bill promoted by the Institute of Architects of the Transvaal and supported by the Society of Architects providing for the registration of architects has passed both Houses of the Legislature of the Transvaal.

The Adjourned Special General Meeting of the Royal Institute of British Architects for the consideration of the revised by-laws, for the announcement of the results of the poll, and for the confirmation of the premises resolution, announced to be held Thursday, July 15, is postponed. Notice of the date of holding the meeting will be issued to members within a few days.

The British Fire Prevention Committee have continued their series of fire tests with doors by testing a large roller shutter to a 7-foot opening, the temperatures ranging up to 1,800 deg. F., followed by the application of water from a steam fire engine, the test lasting for 2½ hours. The members and visitors were received by Mr. Edwin O. Sachs, F.R.S.Ed. (chairman), Mr. Percy Collins, J.P., and other members of the Council and executive, and there were present among others the representatives of nearly all the Government departments concerned, as also a number of municipal officials. The report on the test will be issued in due course by the committee. The testing arrangements of the afternoon were in charge of a sub-committee comprising Mr. Ellis Marsland (directing member), Mr. J. Herbert Dyer, Mr. Fulkes, and others.

FORTHCOMING EVENTS.

Friday, July 16.

Architectural Association. Exhibition of work done in the School of Architecture, and Award of Prizes, 3 P.M.–6.30.

Saturday, July 17.

Bristol Society of Antiquaries visit Malmesbury and neighbourhood.
Society of Architects. Students' Sketching Excursion to Merstham and neighbourhood.
Leeds Health Congress, organised by the City and University of Leeds with the co-operation of the Royal Sanitary Institute and the Royal Institute of Public Health, July 17 to July 24.

Wednesday, July 21.

Egypt Exploration Fund: Lecture on the recent discoveries at Abydos and Mahasna, by Mr. E. R. Ayrton, at King's College, 160 Strand.

Thursday, July 22.

Society of Architects' visit to Messrs. Thomas Lawrence & Sons, works, Bracknell, Berks.

Friday, July 23.

Royal Archæological Institute. Annual Meeting at Lincoln, July 23 to July 30.

Saturday, July 24.

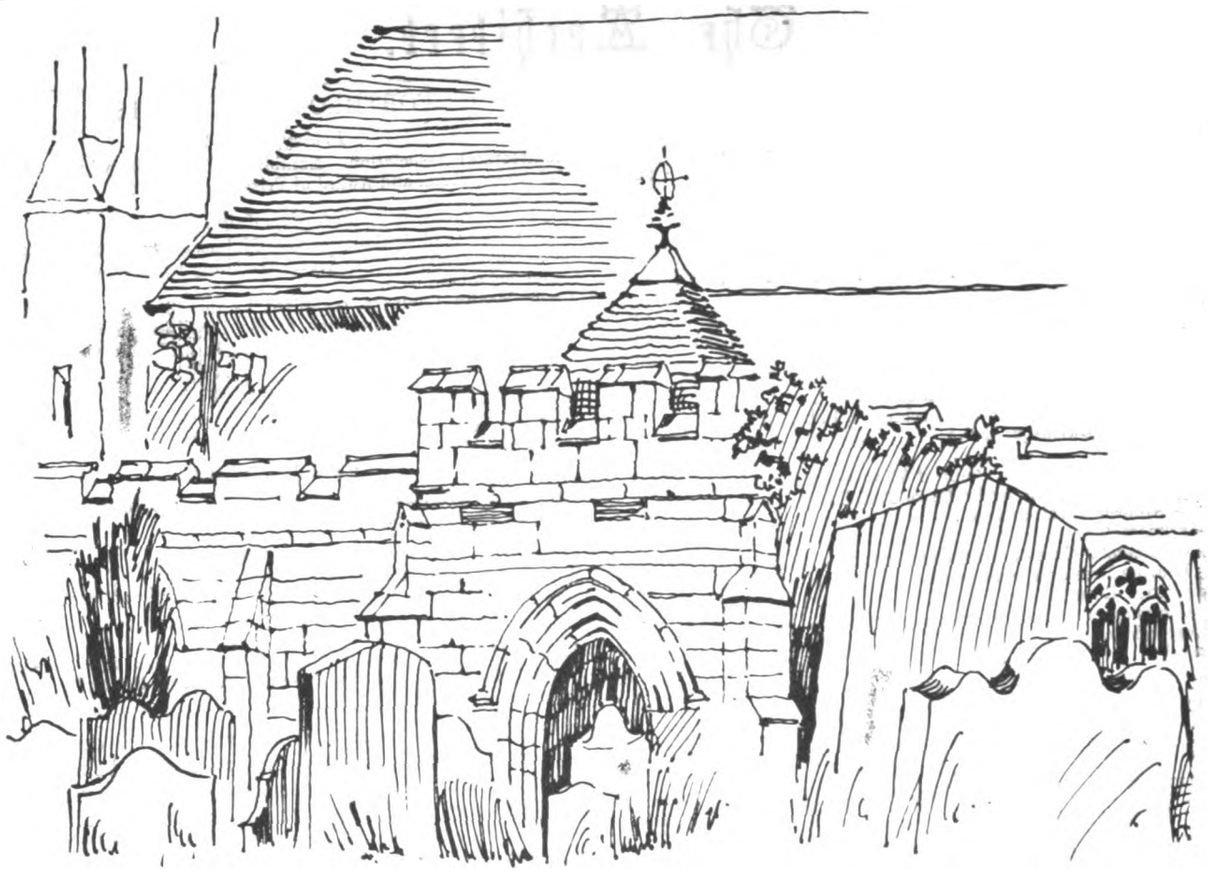
Architectural Association. Third Summer Visit to "Ardenrun," near Godstone, Surrey (a house by Mr. Ernest Newton).

SCHOOLS FOR ARCHITECTS.—I.

THE ROYAL ACADEMY.

THE Royal Academy of Arts does not exist only to furnish for the enlightenment or amusement of the public annual exhibitions of executed works by artists, present and past, nor to mark a high level of achievement by enrolment amongst its membership; it provides also instruction for art students of a very high quality, and that gratuitously. The architectural school, with which we are immediately concerned, is not for the tyro, but is open to all students of architecture sufficiently advanced to be able to profit by the instruction given, without limitation of age, creed, or nationality, and the object of the instruction is to educate the student in the most important of all the qualifications essential to an architect, the ability to design architecture. Design, and design only, is then the subject of study in the architectural school of the Royal Academy.

Although there is now no limitation of age for the architectural student desirous of entering the Royal Academy school, the best age at which to commence work therein is about twenty-one or twenty-two. The average student has at that age attained sufficient proficiency in draughtsmanship and adequate knowledge of construction and of the architectural work of the past to fit him for taking the fullest advantage of the opportunities that the Royal Academy offers. By entering at the age of twenty-one or twenty-two the Royal Academy student may hope also to gain one of the valuable travelling studentships at that period of his career when the opportunity for extended travel and study of old work would be most beneficial to him.



In order to gain admission to the Royal Academy school a student must prove that he has learnt to draw, and for that purpose must submit (1) a measured drawing (plan, sections, and elevation) from his own notes and measurements, with his original notes; (2) drawings of each of the three classical orders, the columns being 12 inches high on the paper; (3) an original perspective sketch; (4) a shaded drawing from a cast.

When these drawings are approved the student is admitted as a probationer, and as such is required to produce further drawings in the school by way of examination. For this purpose he has to make (1) a drawing from memory of one of the orders to half-inch scale, in two hours; (2) a shaded drawing from a cast, the same size as the original, in five hours; (3) the plan and elevation of a building from his own notes, the notes being also submitted, four hours; (4) an architectural design for a subject selected by the visitor for the time being, twelve hours. The probationer has also to pass an examination in the history of architecture and in perspective. Having passed his examination, the probationer is admitted as a student for a period of three years, and is then fairly launched on his career through the Royal Academy school.

It should be noted that the entrance examination is in no sense competitive, but qualitative, inasmuch as that, at present at any rate, the number of qualified entrants in each year does not exceed the number of places vacant. It might, of course, happen that more students might desire admission than the Royal Academy could accommodate, and in such a case the entrance examination would become competitive, but we believe the desire of the Council is to augment rather than to restrict the number of students in the architectural school, so that it would be only sheer necessity that would compel them to exclude any properly qualified student. But, as we have already said, the Royal Academy school is not for the tyro, so that the standard of draughtsmanship required is by no means low, though it is, on the other hand, not unduly high for those serious and able students who have reached the desirable age of entry.

The school year extends from October 1 to the end of the following July, and is divided into four terms, during each of which it is under the direction of one of the four distinguished architects who act as visitors, and who are at present Mr. T. G. JACKSON, R.A., Sir ASTON WEBB, R.A., Mr. JOHN BELCHER, R.A., and Mr. REGINALD BLOMFIELD, A.R.A. These visitors make a practice of attending one evening in each week during the term in which the school is under their direction. They set the subjects for design, and criticise, in the true sense of the word, the work of the students—that is, their criticism is not destructive or carping, but suggestive. In our inspection of the work done by the students under the direction of the present visitors, we were struck by the absence of any attempt on the part of the students to follow the manner of the particular visitor under whom they were working, showing that there is no danger or probability of a student's individuality being warped or crushed by academic instruction. It is, in fact, quite impossible to guess from the treatment of the designs who the visitor might be that superintended their production. Besides the four members of the Academy who act as visitors, students have the advantage of the guidance and instruction of a master of the architectural school, Mr. C. DE

Digitized by Google

SOUTH PORCH, BATTLE CHURCH, SUSSEX.—FROM A SKETCH BY BANISTER FLETCHER.

GRUCHY, a gentleman who has made his mark as one of the finest architectural draughtsmen of his day, and who is in attendance on every evening that the school is open.

Design is taught by the method of preparing a set of drawings, completely worked out, for one subject in each term, and besides drawings, students are encouraged to sketch out their designs in the solid by modelling them in clay, thus cultivating the faculty, so necessary to the real and capable architect, of thinking in three dimensions. Modelling of carved ornament from their own designs is also allowed to the students, and we have seen some very capable work in this direction. We think this branch of study might be further extended, and the students encouraged to model from each other's drawings, as well as to make drawings from each other's models. In this way they would learn one of the most difficult accomplishments of an architect, the representation in a drawing of carved ornament so as to adequately convey to a craftsman the intention of the designer.

Every student in the Academy school is encouraged to keep before him the goal of a travelling studentship, of which there are two, offered in alternate years, the one for travel in England and the other, carrying with it also the gold medal, for travel abroad. In order to qualify as a competitor for these prizes, the probationer who has been admitted as a student is required to do a certain minimum of work in each of the three years through which his membership of the school extends. During his first year he has to make three designs, one of which he must submit in competition for a 15*l.* premium. During this year he is also required to attend three courses of lectures (in all about twelve or fourteen) on painting, sculpture, and architecture respectively. One of the weak points of the Academy system is this question of lectures. Attendance only is necessary, and a student is not required in any way to show that he has benefited by the attendance. The lectures, which for the most part make excellent reading, have not always been delivered in such a manner as to make them readily comprehensible to the attendants, we cannot say listeners. Both lecturers and students seem to be obsessed with the feeling that delivery on the one part and attendance on the other are all that are required. The time at which the lectures are delivered is also not very convenient to young architects, who at the age of attendance at the Academy school are usually paid assistants, earning their living in the offices of employers whose business is apt to be somewhat disorganised by the attendance at lectures. Another weak point of the Academy system is the short time in each evening for which the school is open, two hours from 6 to 8 P.M. Out of this two hours the time required for preparation and settling down and for packing up has to be taken, so that the net time possible for steady work is quite small. Few students either work or live next door to the Academy, so that when the time of travelling to and from the school is added, the result is that an architectural student spends some 3½ or 4 hours in an evening for not more than 1½ hours solid work.

Having complied with the stipulations for his first year's work, our student aims in his second year at competing for the 25*l.* premium by submitting one of at least five complete designs prepared during the two years. Thus in this period the student may, if industrious, have completed eight designs; but he must have completed five in order to be eligible as a competitor for the 25*l.* premium. Similarly by the end of his third year he may have made twelve designs but must have completed six, if he desires to compete for a travelling studentship. Thus having during his three years studentship attended the lectures, completed six designs, and competed for the premium of 15*l.* in his first year, and of 25*l.* in his second year, not necessarily successfully, the student may apply to the Council for permission to compete for a travelling studentship, this permission being almost invariably granted.

At the end of his three years' studentship a student may apply to the Council for permission to renew his studentship for a further period of two years, to obtain which he must have completed seven designs, have attended the lectures, and must submit three of the designs done in the school.

Digitized by Google

The extension is usually granted, and the student then has further opportunities of competing for the travelling studentships.

The drawings for the travelling studentships and gold medal are not made in the school, but in the student's own home or office, and, in addition to the studentships and the premiums already mentioned, there are prizes open to him for modelling, colour decoration, perspective, and measured drawings.

Thus it will be seen that the advantages offered by the Royal Academy in its architectural school are very great and valuable—gratuitous instruction of the highest possible quality in design, sympathetic encouragement of the development of personal individuality and ability, many and valuable prizes, and the companionship of the crème de la crème of a student's contemporaries.

NOTES AND COMMENTS.

THE decision of the Select Committee of the House of Commons that had under consideration the provisions of Part V. of the London County Council (General Powers) Bill, in finding the preamble of the Bill proved, practically ensures the proposed modification of the thicknesses of external walls in the case of steel framed buildings, but is a slap in the face of the Council of the Royal Institute of British Architects, whose opposition to the proposal of the County Council to make regulations respecting the internal structure is swept away. As we have said before, we cannot see that the external parts of a steel frame structure can be considered and judged as to their adequacy or otherwise without reference to the internal framework to which they are connected, and by which they are in part supported. The question of appeal seems to be a little complicated, and to our mind illogical as now arranged by the Committee. Why an appeal from the decision of a district surveyor should be made to a police magistrate, except for the sake of analogy with other procedure under the London Building Act, and an appeal against a decision of the County Council relating to modifications of Clause 30 of the Bill should be made to the Tribunal of Appeal, we are unable to understand, inasmuch as in both cases the appeal is likely to be upon points of scientific construction rather than of law.

THE letter in our correspondence column on the subject of the Middlesbrough Library Competition shows once more the weakness of the single-assessor system of deciding competitions, and also how strongly is maintained in the present government of the Royal Institute "the right divine of kings to govern wrong." When an assessor has been appointed, has made his award, and his award has been accepted by the promoters, it has been proved repeatedly that even if the assessor makes a flagrantly unjust or incorrect award, the position of the aggrieved competitors is practically hopeless, though we hope that this will not prevent the competitors in this particular instance from taking counsel's opinion, and, if necessary, testing the point in a court of law. It is really a very important question for the many architects who take part in competitions whether a wrongful decision of an assessor is binding upon everybody in any event, and in our opinion it would be quite justifiable for the Committee of Defence of the Royal Institute to arrange, and the Council to sanction, a friendly action as a test case on the legal aspect of the question. We are perfectly aware that under the present government of the Royal Institute such a thing is incredible, and that the aggrieved competitors will have to fight their own battle. The one firm article of creed with the present rulers of the Royal Institute is that the President, like the King or the Master of a masonic lodge, can do no wrong, and the Council may be trusted to uphold the decision of an assessor appointed by the President through thick and thin. The Institute regulations for competitions declare that it is the duty of an assessor to determine whether designs comply with the conditions, and if not to exclude them. In this case the assessor has decided that the design he placed first complied with the conditions, and as far as the President and Council of the Royal Institute are concerned, there is an end of it. Whether the assessor is right or wrong makes no difference.

THE article on the sanitation of Winnipeg, which we publish in this issue, should be of interest to those of our readers who contemplate taking part in the meeting on August 25 of the British Association for the Advancement of Science, which is to be held in the Gateway City of the Canadian North-West. Few cities even in Canada have made so remarkable an advancement in recent years as Winnipeg, whose population, which in 1901 was 42,000, had at the end of 1907 increased to 118,000, and there is therefore a fitness in the meeting of the British body that has for its aim the advancement of science in a city of the Empire that has made, and is still making, such great progress in material wealth and resources.

FOR a specimen of the extent to which some members of local governing bodies will carry their principle of haggling into their dealings with professional men the recent proceedings of the Guardians of the Southampton Union would be hard to beat. On a recommendation by the Workhouse Committee that Mr. A. F. GUTTERIDGE should be appointed architect for two new pavilions and an extension of the nurses' home, an endeavour was made to carry a resolution "that applications be invited by public advertisement for the position of architect of such buildings." The attempt was, however, not successful, and the hagglers were forced to be content with an amendment that Mr. GUTTERIDGE's terms should be accepted "unless the phthisical pavilion be on the same lines as the present pavilion, with only balcony and French windows added, when it be suggested that Mr. GUTTERIDGE should accept 4 per cent. for that purpose, and no commission be paid on the heating apparatus." We wonder whether the Southampton Guardians would expect their tailors to make them new coats for ten shillings less than the old ones because they were to be the same pattern, except that the new ones were to have a velvet collar and three more buttons.

THE British Constitution Association having done good work already in promoting a conference of representatives of organisations connected with land, and impressing upon the Government the matured views of those best qualified to judge as to the effect of the Budget proposals on property in land, will hold a second meeting of the Conference at St. James's Hall, Great Portland Street, on Tuesday next, to consider the reply of the Government to their deputation.

TAXING the land is killing the goose that lays the golden eggs. It is not a means of robbing the rich to pay the poor, for land is of no value to its possessor till he has in some way or other paid someone else to help him to get something out of it, and hence the general consensus of opinion amongst experts on land valuation, that if the Government by taxation practically makes it impossible for the landowner to employ others the whole nation suffers.

THE report of Dr. HOUSTON's investigations on the effect of storage in the purification of London's water supply, of which we published an abstract some time ago, has been supplemented by a further report on the ability of the cholera microbe to survive under the conditions fatal to the typhoid microbe, from which we are rejoiced to learn that in this case also, against one of the most dreaded of our epidemic diseases, we are practically safeguarded by the simple and easily applied precaution of storage of our drinking water.

WE trust that there was something more than polite after-dinner gratitude influencing the remarks of the President of the Board of Education when he extolled the

Digitized by Google

work done by the Carpenters' Company in the cause of technical education. It is refreshing to find a member of a Liberal Government admitting that there is anything good in a City Company, but the work done by the Carpenters, the Leather-sellers, and other even less wealthy Companies like the Blacksmiths, must convince the most sceptical that there is some good in the Corporation and its Companies.

A CONSIDERABLE amount of feeling appears to have been aroused in Birmingham by the recommendation of the General Purposes Committee to the City Council that the tender of Messrs. WARING & WHITE, LTD., at 128,744*l.*, should be accepted for the superstructure of the Council House extension, and some of the members of the Council were prepared to support the acceptance of a tender higher by 5,500*l.* from a local firm of builders. The great argument, however, that appears to have influenced the majority was that Messrs. WARING & WHITE were prepared to undertake the completion of the work in two years, as against the three years required by other tenderers. It was urged by the opponents of the committee's recommendation that Messrs. WARING & WHITE were a firm of Anglo-American financiers and not builders. Rather a dangerous and two-edged argument to use, as it is tantamount to an admission that our English builders can be beaten out of the field, both for cost and efficiency, by an organisation of smart individuals who are men of business rather than builders. The old-fashioned builder, even in Birmingham, whose citizens usually pride themselves on their smartness, evidently requires to learn more about business, as well as building, before he can hope to stand as a contractor alongside the American trained man who studies the science of business.

THE new St. Paul's Bridge is not to be carried through without opposition. The advocates of Blackfriars and Southwark Bridges are up in arms. Naturally, every new bridge or other avenue of communication that tends to reduce congestion on existing lines of traffic threatens the vested interests of those who benefit by their proximity to such existing lines; but if these vested interests are always to be respected, improvements for the benefit of the general public can never be brought to completion.

ONCE again the "unco guid" is up in arms against the study of the nude. In this case a councillor of York City has fallen foul of the life class for lady students at the York School of Art, but it seems that every care is taken at this school to avoid, we will not say undesirable features, but even the wounding of the feelings of all but those whose pruriency is evidence against themselves. It is quite unnecessary to urge on any healthy minded person the advisability—nay, the necessity—of study from the nude for all who desire to be painters or sculptors.

COMPETITION FOR TRAINING COLLEGE AT HULL.

THE City of Hull Education Committee invite architects to take part in a competition for a proposed College for the Training of Teachers for Elementary Schools, and as the instructions issued bear the names of both Dr. J. T. RILEY, the secretary of education, and Mr. JOHN W. SIMPSON, F.R.I.B.A., the assessor appointed, it may be presumed that, in this case, the fiasco of Middlesbrough will not be repeated, and that intending competitors may feel confident that the instructions and conditions are approved by the City of Hull Education Committee and the assessor, and will not be disapproved by the Council of the Royal Institute of British Architects.

They are also entitled to expect that the assessor will exact compliance with the instructions he has signed, but, on the other hand, competitors ought to be careful to distinguish between those clauses in which "must" and those in which "should" is used.

The proposed training college is to provide accommodation for (1) a hostel for fifty men students, (2) a hostel for 100 women students, (3) a hall and lecture rooms, (4) refectory and kitchens, (5) a principal's house, (6) a gymnasium, (7) a porter's lodge and entrance gates. The detailed requirements for each of these units are clearly described in the instructions, though they are not so fully given as to render unnecessary individual study or experience on the part of competitors.

No definite sum is fixed as a limit of cost, but it is stipulated that "all designs submitted must be of such a character as not to exceed in cost" 5*d.* per cubic foot for the gymnasium, and 7*d.* per cubic foot for the other units, a low enough figure seeing that fire-resisting materials are required for floors, partitions, and staircases.

The site is an irregular one of trapezoidal shape, with a frontage on its shortest side of 445 feet to a road. It is practically level, and contains 15 acres, so that there is ample space for the college and playing fields, &c.

The drawings required are block plan, to scale 40 feet to an inch, plan of each floor, sections and elevations as necessary to fully illustrate the design to one-eighth scale, and an outline perspective and drawings have to be sent in on or before September 20 next.

ARCHITECTURE: ITS TRUE PRINCIPLES.—XIV.

By R. OWEN ALLSOP.

BREADTH.

IMAGINE a small country house composed as follows:—Patches of red brick and of stock brickwork, a patch of tiles, of rubble stone, of weather-tiling, of sham half-timber work; a brick bay, a stone bay, a wooden bay, and roofs broken into senseless masses. Such a building may have some qualities; the one that it certainly has not is *breadth*.

The opposite to breadth of effect is meanness. A building characterised by breadth is the outcome of a broad mind; the petty patchwork is born of the mean mind. Either of that or of ignorance.

A dozen rooms arranged in one rectangular block would be a broad treatment; the same "stuck" together anywhere and anyhow, as first they occurred to the "designer," would be petty and mean. The term "breadth of effect" seems variously employed, but it most correctly designates a liberal broadness of act, kind, or manner. The term is good and expressive. We see too much of small-minded design—ideas not only cribb'd and confined, but having quite an expression of grasping meanness. No amount of wealth of work in detail can give breadth to a design not conceived in a broad spirit.

Breadth implies purity of style—using the term style to signify rather a mode or manner than some special antique, bygone method of design. It assumes something the antithesis of a museum-like collection of architectural devices worked into a general plan and grouped into a building. It does not follow that a much-broken composition lacks breadth as a direct result of the great multiplicity of parts. Our first example well indicates what breadth is not, and it therefore follows that restraint and simplicity and oneness of method are the means of obtaining broad effects. A picture lacking in the quality of breadth is "patchy," full of restless, ill-judged effects of light and shade, or perhaps crammed full of diverse and incongruous objects. A very little will spoil an effect of breadth just as a very small wrongful action will destroy a whole effort that is otherwise commendable. Fig. 34 is an example.

Consistency or constancy, even, are terms somewhat equal in expressiveness of the attribute of breadth. If a design be conceived in a certain antique style, the style should be respected and maintained throughout, otherwise the breadth of effect is missed, and petty changefulness will be apparent. Certain needs of practical service in the art

Digitized by Google

of the architect may bring about a grouping of features not of itself broad; his skill then will be shown by so arranging matters that the evil appearance is amended, or at least mitigated. Such, however, is not often the case, a petty, mean, paltry design being rather the outcome of a mind similarly attuned, or of gross ignorance of all art principles. The careful use of materials—the fewest consistent with the effects intended—assists in getting a broad, generous, noble appearance. Possibly the term most expressive of the opposite of breadth is "patchiness." Economy—as distinct from meanness—cannot affect the value of breadth obtained; indeed, it will lead to it by avoiding the adoption of over-elaboration.

We find many painful examples of otherwise imposing stone monumental edifices ruined as to breadth by *patches* of red brickwork. This seems to be essentially a modern vice. No monumental building primarily and in the major portion built of stone is improved by a brickwork patch—which does not say that monumental brick-and-stone buildings cannot be produced. Variation when it destroys breadth is bad, yet variation is the essence of novel effects; hence it must be a very undesirable kind

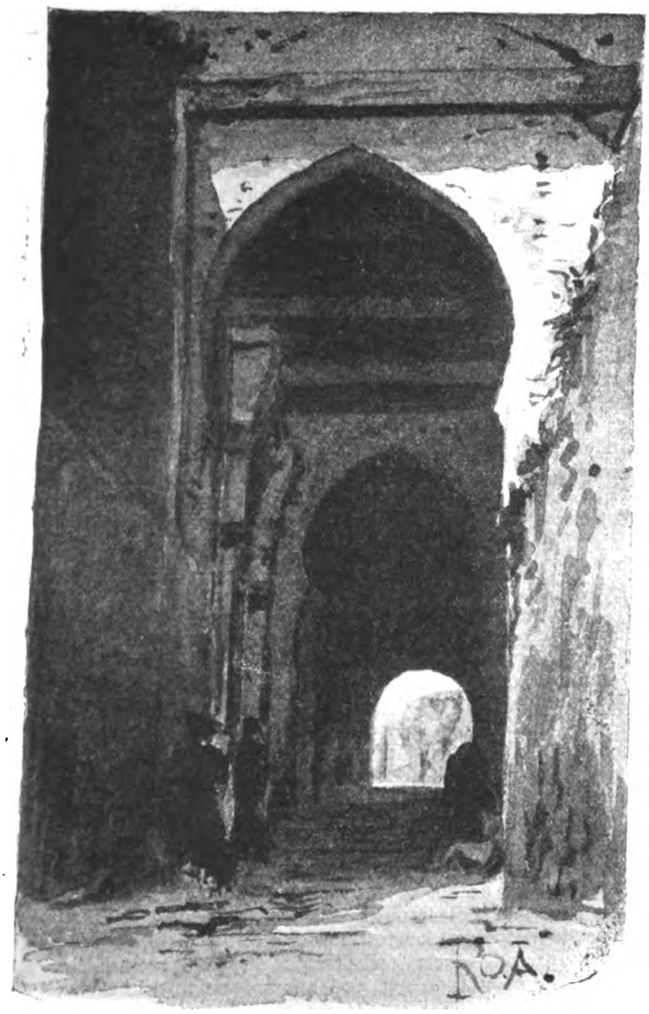


FIG. 34.—GOVERNOR'S PALACE, TANGIER.

of variation indeed that is prejudicial to general composition.

Breadth is best assured by reticence in the matter of enrichment and of what may be termed minor composition—the arrangement of subsidiary masses. The term "breadth of effect" is rather a result than a principle. It is an ultimate aim, and is closely associated with the idea of unity or oneness of effect. Due consideration of the great law of domination and subordination—or, more correctly, the law of subordination—will therefore be the guide to obtaining broad massing of parts. If patchiness were not aggressive it would simply result in variety, but the greatest evil of patchwork is that each patch becomes insubordinate and tends to intrude, to thrust itself (for itself) on the notice of the spectator. The effect of time is to harmonise patches; therefore, if time be given, we get breadth in some respects; but as the idea of architecture is to produce something at once of itself pleasing, it cannot be allowed that the effects of age in improving a building composition is any kind of credit to the architect.

The endeavour to obtain breadth of effect often results in barren monotony, as when a tall building commences with storeys of absolute plainness, and—with some vague idea of obtaining breadth—the designer carries up the rest of the façade in this manner. The result is merely a painful exhibition of the shame of the nakedness of the designer's mind. We may see examples of this. It was not lack of money to pay for "work," but that the architect, vaguely aware that in some way simplicity and dignity go together, had mistaken baldness for simplicity. It is quite evident that elaborate richness is not of itself detrimental to breadth of effect. No one would complain of lack of breadth in the west front of Amiens. It is to be supposed that the production of rich architecture that on all points satisfies the most exacting critics, constitutes a most difficult part of an architect's work; and it is to be noted that the simplicity of the British Museum front and that of a barracks stand on a different plane. The first has resulted in an effect of dignity not easy to parallel; the latter is mere baldness. For an effect of open-handed, generous broadness, combined with relative plainness, it may be difficult to find any better example than the main façade of the Goldsmiths' Hall.

Consistency of style—as a mode of design rather than a variety of bygone architecture—seems a fundamental necessity for breadth. We feel that the round arch in fig. 34 has quite destroyed the general breadth by providing a jarring note; and that this evil effect would remain even if the temporary obstruction in the passage-way—creating a piece of intrinsically ugly form—were removed. The artist appears to regard "breadth" as a result primarily of massing of light and shade, and the careful avoidance of spottiness. In matters architectural, light and shade effects must be considered as secondary—brought about by, and arising from, *form*. Hence consistency in form—as square-headed or arched voids—gives breadth, where intermingling of such leads to the loss of this highly desirable quality. (*To be continued.*)

TOWN PLANNING.*

Ancient and Modern Capitals—Improvement of Existing Towns—The New Towns of Greater Britain—Need of Education for us in Town Planning—Enlargement of present Scheme of Professional Education—Town Planning a New Enthusiasm.

THE creation of a city has a new-world sound about it. The Englishman first, perhaps, thinks of America, where everything civilised has had to be created in the space of a recent epoch, and where there must be a most extensive assortment of experimental town-planning schemes available for European statesmen to consider, digest and appropriate. America has the only modern capital of any account hitherto built on plan, and our great daughter nation, without the glamour of historical association or of style or site, has built with a foresight and design worthy of the great name of Washington. To-day also the opportunity has come to Australia. Wealth, dignity and a fame second to none among the daughters of her mother have grown to be hers in the swiftly passing century of her development. From among the capitals of her provinces, great as they are, she now moves forth to seek a federal metropolis with intention and power to accomplish, we hope and trust, the greatest stride the modern world has witnessed of town planning on the grand scale. It is Australia's to embody in a complete and new continent the wisdom of her government with, we seriously but nervously trust, an architecture competent and noble, characteristic and graceful, the fruit of the ages and as vivid with artistic life as the Commonwealth is with intelligence and power. This is a day indeed for such a subject as ours.

The modern conception, infused with the spirit of ordered

* A lecture by Professor A. Beresford Pite, delivered at Hampstead on July 14 in connection with the Town Planning and Housing Exhibition.

Digitized by Google

arrangement, planned with spacious dignity and architectural resource, has to create its own interest and maintain national dignity without the serener charms—why call them adventitious?—such as yielded by the Golden Horn, the yellow Tiber, or our nut-brown Thames to their respective metropolitan cities. The equally precious traditionary blessings of Justinian's building fever, Michel Angelo's tremendous scale, or Wren's capacious genius, attach to the glory of these ancient capitals; but the provision of such equivalent virtue may yet be buried in our race waiting to be evolved by circumstances of education, environment and opportunity. To this end we speak of it to-day. The castle must be designed, be imagined, in the air before it can be drawn or erected upon the earth. The complete idea of a modern city is not, like a historic capital, the product of the mysteries of unrevealed history, but grows by the application of geometry to the courses of traffic, the areas of business or residence and of recreative perambulation, not forgetting the monumental value of spaciousness rather than of compression. One generation, or at most two, is required to realise for this what the laborious tides of time and accident have effected for them. The results are, of course, wholly different and not comparable. The ancient capital has been perforce the shuttlecock and plaything of time and chance, and therefore as well the creation as the creature of natural forces, while the modern city is the deliberate and concrete expression of the work and hope of either an association or an architect.

The full extent of the subject of town planning has certainly as yet barely dawned upon the minds either of legislators or architects. Garden and ideal cities, new suburbs, parks and open spaces, are each extensive subjects and fall within a similar group of ideas. Total effect, architectural grouping, regularity of plan and "lay out," completeness and balance govern the ideal and create the plan to be evolved by the ordered building of the nucleus that shall grow into a great city without distortion or waste of power. This subject, though large, is capable of discussion, and helpful principles can be elucidated to guide and stimulate the formation of an ideal town-development scheme.

The improvement of existing towns is, on the other hand, not so easy of useful theorising. A primary factor will exist in each town which may bear little or no illustration by or application of the principles laid down for an ideal town plan. Towns are more irregular and various in their characteristics and possibilities than even men or women, and an abstract doctrine which might avail for street improvement, say, in a university city like Oxford, would be hopelessly inapplicable at Birmingham. London, Edinburgh, Dublin, or Cardiff would each obviously demand different management on the basis alone of natural configuration, to say nothing of the almost equally urgent considerations of national and local historical monuments and character. The great towns which are almost purely commercial or manufacturing in purpose will vary further, while the class represented by Cheltenham, Harrogate, or Tunbridge Wells and Brighton is governed by quite other hopes and purposes. Local improvements will illustrate how completely circumstances alter cases, and the attempt will be futile to lay down principles that would be adaptable for the guidance of unintelligent boards or officials. A cultivated acquaintance with the beauties of famous streets, public places and groups of buildings will provide a useful standard of ideas, and may lead to that quickened perception of advantage of position and directness of access which is the asset of a good military general. Rigidity of idea or the application of the principles, for instance, that underlie the geometric setting out of a model city plan may provide an engine for destroying the local interests and character of a town. Let old bottle municipalities beware of the new wine of modern doctrine, and cultivate an earnest local enthusiasm, it may be even for a precinct, a close, or a buttery lane, rather than conclude that because electric tramways are the fashion in London suburbs they will prove the importers of fresh vigour into a delightfully crooked old-world city. The wide differences that affect any consideration of the improvement of existing towns, inland or centrally planned, riverside or riparial in system (as London), or seashore with a wide unlimited front extending fan-like from the point of landward approach, prevent any attempt to deal with town-improvement schemes now. It must suffice to say with what interest the architectural profession have viewed the preparation and promotion of Mr. John Burns's Town-planning Bill, and how they are convinced that the ultimate success of its proposals for the general preparation of town development schemes depends upon a wise and educated acquaintance with the great subject of town architecture as a whole. This conviction becomes an anxious prepossession when the possibilities of misconception and failure in the design of schemes which are to acquire a legislative fixedness are contemplated. The need for a proper course of training for the work of designing and preparing town-planning schemes therefore becomes the most anxious question of the day to architects, and one to which it is not too soon to give immediate attention.

Happy is the nation that points to her completed cities, perfect in their orderliness and having the special and rare quality of fulfilled design, where foresight has conquered accident and civilisation is conveniently expressed in geometry of plan and by rapidity of transit. The joys of such cities are like those of a Tantalus to Englishmen; our architects describe this blessedness and incite enthusiastic statesmen to recreate such Elysian fields at home, here in poor, unkempt, untidily free Britain; for if Paris or Washington, why not in Piccadilly, merry Islington, Edmonton, or Ware?

To Greater Britain, however, the subject is a present and urgent one. The world renews its youth and replants itself in sheds of corrugated iron, roughly grouped on pegged-out claims, which ere long shuffle out of their caterpillar and chrysalis coils and solidify with amazing rapidity into vigorous and powerful municipalities and capitals which should also be dignified and beautiful.

To-day, while we at home are gardening the suburbs of our old incorrigible cities, the Empire is town-building in earnest, perforce from the impulse of development and heartily moved by the fresh vigour and renewed naturalness of those humane instincts of building and gregariousness which are wider than either the building trade or architectural profession. This town-planning instinct—for it is nothing less in man than in ant, bee, or beaver—has up to the present received no recognition from its proper foster-fathers, the authorities of building education and practice. Empire building, I speak literally, not figuratively, of the incessant daily processes of foundation digging, walling and roofing, without the aid of any ordered system of mental exercise, without the specialised instruction afforded by study and experience, in every fresh extension or renewal of town life is laboriously and disastrously repeating huge blunders and petrifying stupidities and ignorances which are a reproach to any people.

For much and all of this a sound and simple architectural education would be something more than a palliative; this evil is wrought more by want of thought than want of heart in willingness to do the best; and the best is the wisest both economically and delightfully.

You may note how incessantly the so-called orders of Classic architecture are reproduced as an alphabet of design more or less correctly and studiously in the various classes of modern buildings in all climes. These forms have been laboriously acquired, drawn and reproduced. Were half the time and space so devoted by instructors and handbooks afforded to a broader view of what makes for the architectural dignity and beauty of buildings, streets and cities, the modern world would have more clearly revealed in its current monuments the wisdom of its makers.

There is indeed room in all our centres of architectural life and education for a constant attention to the subject of the proper design of towns. All of us have to do with town life, and are actually in these constitutionally democratic days the paymasters and collective dictators of our own municipal officers, who build, regulate and plan our streets, or should do so; and apart from any infusion of architectural thought into a general scheme of educational reform, which is greatly to be desired, for works of art and nature should not be divorced or unequally yoked in the education of a just mental balance. The specialised training in architecture of its own practitioners ignores this subject gloriously.

The recognition of the problems of our own Colonial life, which are more extensive, interesting and beneficial than most, if not all, of the stock historical and ornamental exercises of the architectural student, urgently claim attention at headquarters. The stock properties of professional education are exercises in purely local architectural limitations both in æsthetic history and in constructional practice. An English architect practising in India questioned me the other day as to suitable precedents for the case of a clergyman who had instructed him to design a church in the Norman style for an Indian station. It is surely bad enough to put the hands of the clock back eight centuries at home in ecclesiastical building, but to employ local English time, and that eight centuries late, where sunshine, seasons and

Digitized by Google

simoons all differ is a marvel of the refined perception of the intelligent mission of architectural expression. The practical art of building construction is, moreover, not as yet taught as an exact science the principles of which are capable of universal application, as indeed they are on every spot on this habitable globe where the law of gravitation works. All materials and climates yield obedience to principles of design which are not more abstruse or difficult of perception than those which govern British standard bricks or Baltic scantlings. The chemist, naturalist and engineer go forth into the wider world of Britain beyond the seas equipped for varying conditions and relationships to nature. Why should not the builder and architect, upon whom devolves the conception and construction of multitudinous buildings, be equally furnished by education with a ready knowledge of how to employ his present opportunity and its characteristic materials and purposes?

But such an education, if confined to architectural candidates—that is, to intending professional men—may entirely miss the class of energetic prospectors, probably the most miscellaneous of all classifications. Though it certainly is reasonable and necessary, it would be an amazement out of Wonderland if the necessity of having a proper architectural member of the staff was recognised in the public prospectus of any of those companies which by the development of gold and diamond mines, or coal or otherwise, incessantly create embryo townships which ere long become provincial centres and perhaps capitals. In a general education syllabus should not some practical application of geographical particulars lead to the formation of ideals as to situation, lay-out and growth in the great cities of the world? Lantern-slide excursions would very rapidly involve actual acquaintance with satisfactory examples for criticism and instruction. How to build a town—what comes first—the inevitableness of widenings—the certain increment of values near the meeting place of routes—rapid temporary building as of a camp, with illustrations of how the exigencies of the Roman military castra have until to-day fixed up the facts in dozens of living English townships. All this and much more of vital work could be most profitably sown into the youthful English mind for certain fruitfulness both at home and overseas in the short course of a rising generation. Happily there is more educational elasticity both of outlook and method in all classes now, and one can foresee a new and happy mingling of the Classic and modern sides of the present much-debated school curricula in a study of Greek and Roman civic law and practice applied to the most progressive ideas and facts of the day.

But our point of view as specially educated architects is terribly limited. The present-day architect is not in any true sense a survival of mediævalism or follower of the cathedral builders; he is not even an intelligent archæological product, for you will look in vain among mediæval builders for any trace of the modern delusive vision of the beauty of all that is nearly 200 years old, or of the necessary evil of modern matter. The progressive ancient architect spurned to follow not only the work of his immediate predecessor—the present day does that too, and with marvellous and unfathomable self-complacency—but he refused any undue respect to precedent, and incessantly moved onward gathering momentum each generation from the eleventh century until the sixteenth; the progress of civilisation, craftsmanship and science evidenced in the building arts of England between the times of William the Conqueror and the Tudors—that is, from St. John's Chapel in the Tower of London to Henry VII.'s Chapel at Westminster—is probably unparalleled in Europe. The modern architect moans at the progressive age in which he is cast, and lacking the spirit, imitates the letters and spelling of the builders of Chaucer's day. So the Empire has to grow without his sympathy and aid, lacking a true architectural flavour in the pottage of its common life.

In the new interest of town planning one may foresee and hope for a new enthusiasm for the progressive humane science of building and buildings that will liberate us from the narrowness of our very limited antiquarianism. The history of the world lies most evidently in that of its towns, not merely that they are the physical embodiment of varying epochs of character and power, but are the expression of intellectual forces and character. The architect of a town has a special and vital interest in the civic life of ancient Hellas, and finds in the municipal legislation of Rome, as well as in the pathetic crookedness of the Via Sacra amidst all the grandeurs of the Forums, more secrets of town planning than he has yet suspected. Palmyra, queen of the desert, the still evident greatness of the cities of the southern shore of the Mediterranean, all have secrets to give up of the greatness and science of the world's greatest building empire. Spalato and the later Byzantine greatness of Justinian's school of building, all and each varying and wonderful, are fields yet undetailed for the student of this subject. Here archæology becomes dry-as-dust antiquarianism, but vitally intelligent archæology is a practical training in architecture unrivalled in its mental discipline and opening power. The road building, aqueduct bringing, the permanence of the Cloaca Maxima, are all subjects waiting for inclusion in this branch of architectural study, where the ancient and modern world will unite in the bond of sympathetic pursuit of sanitation and order. In a later period of petty warring States, but of ecclesiastical unity, the Mediæval vision begins to fill the eye, and has strangely attracted modern fancy. Sentiment, properly ordered, is one of the strongest elements in architectural beauty, but let loose upon romantic Mediævalism it has usurped more than its proportion or measure. Modern artists, jaded in their conflict with engineering progress and philistinism, experience with refreshing excitement the historic thrill of a decaying city, and marvel at the playfulness of Time with the garments of a sleeping city; their happy souls number the scars of time, trace with patriotic but artistic fervour the storm marks, assaults, demolitions and recoveries of the almost vanished ancient life. The grass-grown street, the grey oak, the sunken lathings, the faded whitewash, the decaying brickwork and weather-worn masonry are the tonics that art and affection minister to recovery from the fog-laden air of this uncared-for brutally modern age. And they make what use they can of these invigorations, and the semblances of irregularity are imparted not only to plans but to buildings and groups; and this art, creating its own atmosphere, breathes in petty quaintness the romantic air of the past. This humour, this antiquarian hypocrisy, superstition and credulity may be lawfully exercised in private at the expense of those it amuses, but the practical earnestness of town planning forbids such sentimental pantomime. What would a poor motor-'bus do if the texture of Mediæval romance were imparted to the pavement or gradients of the high street, or its pointed acuteness to the angles of the market square? What civil or sanitary authority would tolerate genuine active exsumatory gargoyles in a summer storm? And what use are the symbols of Mediæval fortification, the fruit of blood-bought experiments redolent of feudal oppression and municipal dependence as means of an artistic expression of modern life? All this can be left to become the whim-food of the private client, attesting like the Gibeonitish mouldy bread, clouted garments and rent wine-skins the distance of the journey from the facts of to-day.

In town planning the ancient and the modern divide sharply. We are here in the living present and cannot stay to quarrel longer with the private practice of architects, but preach again the new mission to educate in the essentials of great and noble architecture the race that is building cities around the world to-day and every day without adequate guidance from those who should be entitled to lead.

THE PROPOSED LAND TAXES.

THE Surveyors' Association has followed the lead of the Surveyors' Institution, and has issued a memorandum in which the opinion of many of our leading land surveyors is thus expressed:—

1. *Increment Value Duty.*

The imposition of this duty will seriously affect the value of land of every description, agricultural and otherwise, throughout the country, as investors will naturally prefer to place their capital in securities where they will not run the risk of losing one-fifth of any increased value. The increment value in the majority of cases merely represents deferred interest on the original purchase money, and a duty on that value will tend to retard rather than assist development, for which, even on estates of moderate size, considerable capital is required in the formation of roads and erection of houses. This capital the greater number of owners and builders do not possess, and they obtain it by means of mortgages which the imposition of a duty will make it increasingly difficult to secure. The present depression in the building trade is consequently certain to be aggravated, and unemployment increased. Properties which have been purchased for development have frequently been found on a resale to have decreased considerably in value, and if an increment duty is imposed it is only just that in the event of depreciation a return of that duty should be allowed.

Digitized by Google

2. *Reversion Duty.*

This duty will work most unfairly upon owners who have purchased ground-rents on the faith of the stability of the land laws of the country, the reversionary annual income to be received on the expiration of the existing lease having been carefully calculated in determining the purchase price. Many private owners of ground-rents have purchased with a view to providing, after their death, an income for the support of their families, and the proposed duty will diminish the capital value of that provision. Trustees, life insurance companies, with whom policies are taken out by all classes, building, and land companies, friendly societies and others who have purchased this class of security, will find their investments seriously depreciated, and on realisation will suffer considerable loss of capital.

3. *Duty on Undeveloped Land and Mineral Rights.*

A duty on undeveloped land is calculated to injure building development even more seriously than the increment duty, for the reasons set out above. If the imposition of a duty has the effect of forcing land not ripe for development into the market for building purposes, disaster will follow, as experience has shown. To place a special duty on the grounds of a house, where they exceed one acre in extent, would certainly result in the reduction of the air spaces in and around the great towns, to the general detriment. The "Mineral Rights" duty will cause great hardship to owners of areas already under lease, and in many instances it will be equal to an additional shilling in the pound on the income tax, which is already collected on the capital value of minerals as well as on the income. Minerals generally, but particularly in undeveloped areas, are so uncertain in value that the taking of capital value as the basis for the assessment of a yearly duty is inequitable unless full provision is made for repayment in cases where the valuation shall have been proved by the event to have been wrong.

4. *Generally.*

The proposal that the decision of the Commissioners shall be final is an undesirable and drastic change from the practice now in force in assessing death duties, where an appeal to the High Court is allowed. At the present time, owing to the great decrease in the value of property, the margin on many mortgages has been reduced below the statutory one-third, and the imposition of the proposed duties will cause a still further reduction, so that trustees and others who have hitherto regarded mortgages as one of the soundest forms of investment will be compelled to call in their capital and invest it in other securities; the result being great hardship on, and expense to, the owners of property, and restriction of the capital available for investment in land. The Finance Bill has already had a deterrent effect on the letting of building land, and some of the signatories have experienced instances where contracts, which were on the eve of completion, have been annulled on account of the cumulative taxes proposed, and the cancelling of these agreements will cause an enormous amount of unemployment in the building and allied trades.

LIVING ARCHITECTS.—NO. 12, MR. R. NORMAN SHAW, R.A.

MR. NORMAN SHAW has so far outlived the other leading architects of his day that he is now the *doyen* of the profession, and although virtually retired from practice is still an influence for good in our modern architecture.

NO. 13, PROFESSOR BERESFORD PITE, F.R.I.B.A.

PROFESSOR BERESFORD PITE is not only a professor, but one of the virile architects of the day, and his work, from the appearance of his notable Soane medallion design, is always of piquant interest.

COMPETITION DESIGN FOR MIDDLESBROUGH PUBLIC LIBRARY, BY MESSRS. HALL-JONES & CUMMINGS.

THE plan and design of this building were largely governed by the conditions which fixed the positions of the important parts, and also the nature of windows, height of sills, &c.

It will be seen that the boys' and girls' reading rooms are placed next to the general news room, thereby enabling the janitor to have complete supervision. The general lending library is in the northern part of the site, with the principal entrance and stairs leading to the first floor; and the ladies' reading room adjoins same at the northern extremity. The upper floor is given up to the reference and patents libraries, forming a simple arrangement with the other required rooms.

With regard to the general lending library it appeared that the arrangement shown on plan would be best in order to give light between the book stacks as well as greater convenience to the public.

It was proposed to face the buildings with red bricks and stone dressings, the diaper work in frieze being formed with dark coloured brickwork, and to cover the roof with red tiles.

COMPETITION DESIGN FOR MIDDLESBROUGH PUBLIC LIBRARY, BY T. GERARD DAVIDSON, M.S.A.

THE schedule of requirements was followed closely, and every effort made to yield the largest accommodation from the awkward L-shaped site.

The plan shows the "indicator" system to the lending department but the "open access" could be applied without difficulty.

A broad and somewhat severe treatment in red brick and stone, with a green slate roof, was proposed, and the windows cast their light down the length and not across reading tables and stands. Top lights are used in the reference department.

The departments being on two floors, the librarian's room affords additional supervision over the reference and law libraries, while below the janitor controls the boys' as well as the general reading room.

PELHAM SCHOOL, WIMBLEDON.—NORTH-EAST VIEW FROM SOUTHEY ROAD—AN ENTRANCE DOORWAY—AN ENTRANCE GATEWAY.

THESE schools are to accommodate 1,000 pupils, nearly equally divided among the three departments of boys on the second floor, girls on the first, and infants on the ground floor. The site is about three-quarters of an acre in area. The general arrangement of all the floors is similar. On each there is an ample assembly hall. The east side of the building (securing the best light) is wholly occupied by classrooms. The assembly hall looks to the west, and additional classrooms are placed at either end of the hall. The windows of every classroom are carried to the full height, and each scholar has a left-hand light. With the exception of two rooms in the infants' school no classroom is for more than forty pupils. Each department has two entrances to the playground, with cloakrooms and lavatories ranged round them. The bell tower rises to 100 feet, and contains a supply cistern for 1,000 gallons. The schools are warmed by a low-pressure hot-water system from the basement, and in addition opening fireplaces are in the teachers' rooms and infants' classrooms. The ventilation, besides that of the windows, is combined with the heating system by the use of ventilating radiators for the supply of fresh air. The schools have electric light throughout. Two electric fire-alarm bells are in the corridors of each floor. The elevations are of picked dark brown Crowborough bricks and LAWRENCE'S hand-made red bricks, while the dressings are of Portland stone. The floors are of steel and concrete construction, fire-resisting and sound-proof. The assembly halls are panelled in green stained wood up to 7 feet. The classrooms and corridors have antique glazed tiled dadoes. The style of the building is based upon Early Georgian, which adapts itself readily to requirements of light, ventilation, and arrangement, and, without lack of dignity, has a very suitable domestic character. The contract was made on April 29, 1908, with Messrs. ALLEN FAIRHEAD & SON, of Enfield, for 15,920*l.*, and was completed in fourteen months. The total cost of the building has been 16,457*l.* 15*s.* 9*d.* Among the other contractors were:—Modelled Plasterwork, The Veronese Co., Ltd.; asphalte, The Seyssel and Metallic Lava Asphalte Co., Ltd.; grates, BRATT, COLBRAN & Co.; lift, ARCHIBALD SMITH & STEVENS. The design was obtained by a limited competition, to take part in which there were 172 applications. The competitors were limited to fifteen, with Mr. J. W. SIMPSON as assessor. His award gave first place to Mr. H. P. BURKE DOWNING, F.R.I.B.A., of 12 Little College Street, Westminster, S.W., who has carried out the work; and the buildings were opened on Wednesday last by the Right Hon. Lord ALVERSTONE, Lord Chief Justice of England.

CARLISLE CASTLE.

QUEEN MARY'S TOWER, so called from having been the place where the Queen of SCOTS was confined by order of ELIZABETH in 1568, is situated in the south-east angle of the inner ward. This is a conspicuous feature, and above the entrance can still be seen a very fine piece of thirteenth-century work. The tower is tall and narrow, having very thick walls, and the windows admit very little light into the interior. The tracery and cornice are now very much worn owing to the inclemency of the weather. The exact date of erection is not known. Our illustration is from a sketch by Mr. H. SCOTT-SAWYER, 12 Howard Place, Carlisle.

· CARLISLE · CASTLE ·

WINNIPEG, FROM A SANITARY POINT OF VIEW.

By WILLIAM BRUCE, of Winnipeg.

HISTORY always repeats itself, and it has done so since the world began and will continue to do so until the end of time; consequently Winnipeg will soon require to thoroughly overhaul its defective sanitary work, as some older cities have done owing to the want of foresight in past years.

Winnipeg is the centre of the principal railway lines running through Canada, and it has justly been described as the gateway to the great north-west, with its rich lands, extensive minerals and oils, &c., to be found all over the country and only waiting for capital to develop its wonderful wealth. It is not only the principal railroads that lead to Winnipeg, but the city is built at the junction of two rivers, and the Red River will at least become a great summer waterway for passengers and traffic, as we can see at the present day in other parts of the British Empire.

It is a doubtful policy to go on spending large sums of money, digging wells, erecting pumping machinery, and after the water is brought to the surface to proceed to put it through a softening process, at great expense, when a good supply of water can be got to supply the city by gravitation from one of the lakes north of the city.

The newly elected Council are progressive business men, and it is hoped that they will stop the spending of large sums of money for the digging of wells, and they may with advantage recall to mind the past experience of the city of Glasgow, Scotland. When the City Council of Glasgow took its splendid supply of water from the western highlands of Scotland, it was I think clearly proved that the citizens saved in their soap bill every year as much money as paid the interest on the capital invested in the water supply. Another point in favour of taking a good supply from one of the lakes is the fact that the fire insurance companies must reduce their rates, otherwise local companies will be formed that can cut the rates in two and still retain a large margin of profits to cover all risks. At the present time the fire insurance companies have the defective electric wiring to contend with and take the risk arising from that source, also the risks in connection with the hot air heating in so many buildings, but these are small details that some of the citizens should bring under the notice of the City Council and show the necessity of a new by-law, modern and up-to-date in all its details, to rectify all the defective work in new buildings, so far as the fire risks exist.

It is needless to add that the City Council will with pleasure take the matter up as soon as a case is put before the members.

The most expensive problem in front of the citizens is the sewage question, arising from the want of foresight in the management of this very important question, as the necessary changes will cost the taxpayers an enormous amount of money.

The city as it now exists is built at the junction of two rivers, and both rivers have a splendid fall for all drainage purposes. Both rivers have been used as outlets for the sewers when only one should have been used for that purpose, and only on the north side of the city, that is down stream, past the city. The present city is erected on an area of ground possessing a fall, and all the advantages that are required for good drainage. In other words, nature has provided the water shed of the Red River with a sufficient fall for all the sewage of a very large city, and it only remains for the City Council to take advantage of what nature has provided.

Let us consider what has been done by the civic rulers in the past.

We find that they have not taken advantage of the natural fall of the ground on which the city is built, they have not skilfully arranged the sewers in such a way as to take advantage of the fall of the Red River to keep the banks of the two rivers clean where they pass through the city. In place of taking advantage of what nature has provided, the mistaken policy has been adopted of discharging the sewers into the rivers at the nearest point, polluting the water and leaving the banks dirty, where the rivers pass through the best residential districts and through the business parts of the city. During the summer months one of the rivers is in the condition of an open sewer, very offensive and dirty. The sewers are discharging their contents in a most objectionable manner where large commercial establishments will be erected on the banks of the rivers as the city

Digitized by Google

increases in size. This is the want of capable management and foresight on the part of those responsible for the plan of the city sewers, and it will become a very expensive proposition for the taxpayer when the mistakes must be rectified, and at no distant date, if Winnipeg is to become a large city.

The rivers running through the city should be kept free from the city's sewerage, and now that can only be done by the construction of large intercepting sewers, skilfully planned and of sufficient size to convey all the sewerage from Silver Heights and River Park district.

One of the first duties of the new Council should be to construct all the new sewers to fall in the right direction, that is leading down the Red River past the city, as the day is not far distant when Winnipeg will purify its sewerage, and that time will be hastened forward when cheap power is supplied and various classes of manufacturers have taken up positions within the city limits.

It is not only the general plan of the sewers that is defective, but the want of proper sewer ventilation is a disgrace to the city of Winnipeg, as nearly every manhole grate shows at the present time. A little skill and foresight on the part of those responsible for the present condition of the sewers and house drainage would have resulted in some modern sewer ventilation at all the high buildings erected in the city. This arrangement could have been carried out at very little expense to the city and the nuisance completely removed from the surface of the streets, and prevent the dangerous and disagreeable sewer air from entering all dwelling-houses and business premises that are situated near the manholes.

It is carelessness, the want of knowledge and foresight that has brought on this state of matters, and the question now arises, how is the evil to be overcome?

Under present conditions at the City Hall, all improvement and progress in sanitary work is at a complete standstill. A new sanitary by-law is required accompanied by skilful administration of any new regulation that the Council may adopt. If this important matter is placed in the hands of experienced sanitary experts a scheme can be arranged and the evils removed by adopting a system of sewer ventilation that experience has proved to be very successful in older and much larger cities, that is, to connect to every house drain, outside of the house trap, a four, five, or six inch pipe as a sewer ventilator, carried up through the roof at the side of a smoke flue if possible, so that the heat from the flue will induce a stronger current. In warm climates the sewer ventilators are fixed outside, but that plan will not work in this climate of Manitoba and the north-west of Canada. If it is not convenient to fix the ventilation pipes near the smoke flues, they should not be erected in a cold position, and where iron is used for ventilating purposes, care should be taken to avoid bends at the foot of the pipes, liable to stoppage by rust that falls from the inside of iron pipes. Lead is the most suitable material for sewer ventilators, with long easy bends where necessary, and fixed with cast lead ears, soldered to the pipes, about every three feet apart and well fixed to the walls.

As some people may question the efficiency of this system of pipe ventilation in Winnipeg, the following facts may remove any doubts in relation to the good work accomplished by pipes when used as sewer ventilators. The writer has made a careful study of this important detail of sanitation, and carefully conducted numerous practical tests under all weather conditions, with accurate instruments for testing the air currents discharged at the top of ventilation pipes.

At a low building near a high building the upward current of air extracted from the sewers will average about 60 feet lineal per minute. At a three-storey building from 250 feet to 450 feet lineal per minute. Much depends on the position of the pipes, the manner in which they are fixed, and the height of the building in its relation to other buildings adjoining.

Last December some tests were made in Winnipeg at the following buildings:—

South Fire Hall, 100 cubic feet per minute, or 6,000 per hour.

Crump Block, 65 cubic feet per minute, or 3,900 per hour.

Codville Georgeson, 37 cubic feet per minute, or 2,220 per hour.

Mr. Boyd's residence, 20 cubic feet per minute, or 1,200 per hour.

Sterling Block, local drainage, 33 cubic feet per minute, or 1,980 per hour.

This may be taken as reliable evidence that the sewers of Winnipeg can be thoroughly ventilated by means of sewer pipe ventilators, as in other cities.

The holes in the manhole covers are more than double the size of what they should have been in this climate; but that is a very simple matter, and the area of inlet to the sewers can be reduced by means of sheet iron plates placed below the grates.

If the system of pipe ventilators is adopted at all new buildings and at the rebuilding of property in the centre of the city, the discharge from the manhole grates will soon disappear.

The ventilation of the sewers is only one of many important details in connection with the sanitation of the city that should be improved upon, as the house drainage and internal plumbing requires to be thoroughly modernised for the protection of the health of the citizens. The defects of the present system of house drainage and plumbing are too numerous to describe.

In all large cities where the civic work is conducted on modern principles, the architects show on their plans all the drains, pipes and fittings, and when the building inspector grants a permit to execute the work according to plans approved of, that permit covers all that is shown on the drawings; and the building inspector's staff of assistants includes some practical and trained plumbers, whose work it is to test the drains, soil and vent pipes, and test by pressure, at a station provided for the purpose, all the cocks and valves used by the plumbers for the water fittings of the city. It is usual to charge a small fee of about two cents for testing and stamping each article, and the same men inspect the water fittings before the water is turned on in any building.

In Winnipeg the work is divided into sections. The building inspector has a part, the inspector of plumbing, acting under the city engineer, has another part, and then follows the electric engineer, and his part not only includes his own work, but he also has a say in certain details of construction. In the face of all this divided responsibility, the building by-law plainly reads that the drawings are to show construction and *equipment*. It would be much more satisfactory to owners, architects and the contractors if the city officials agreed among themselves on all the details shown on a set of drawings, and have everything complete before a permit is granted.

What Winnipeg requires at the present day is a complete building by-law to cover all details of a building, and in addition to the printed clauses a number of illustrations should be attached to show two or three different ways of executing work that cannot be well described in print, especially house drainage and plumber work.

The owners of high-class residential property would willingly have all their sanitary work executed in the best and most up-to-date manner. It is to be hoped that the day is not far distant when first class property will have all the drains outside the buildings, all with proper manholes, intercepting traps, all properly ventilated, as it is only a question of care and protection from frost. Of course, all soil and vent pipes must be placed inside in this cold climate.

The British Association meeting this year is to be held at Winnipeg, under the presidency of Professor Sir J. J. Thomson, F.R.S., and it promises to be one of the most interesting of the long series of gatherings held under the auspices of the Association. The inaugural meeting will take place on August 25, when Professor Thomson will assume the presidency in succession to Mr. Francis Darwin, and will deliver an address. The following day the sectional meetings will commence, and the sitting will extend to September 1. Professor E. Rutherford will preside over the mathematical and physical science section. The other presidents of sections are:—Chemistry, Professor H. E. Armstrong; geology, Mr. A. Smith Woodward; zoology, Mr. A. E. Shipley; geography, Colonel Sir Duncan Johnston; economic science and statistics, Professor S. J. Chapman; engineering, Sir W. H. White; anthropology, Professor J. L. Myres; physiology, Professor E. H. Starling; botany, Lieutenant-Colonel D. Prain; agriculture, Major P. G. Craigie; educational science, Rev. H. B. Gray.

Mr. Thomas Mellard Reade, of South Blundellsands and Liverpool, architect and civil engineer, author of more than 200 pamphlets, Fellow of the Royal Institute of British Architects, who died on May 26, aged 77, left estate valued at 8,717*l.* gross, with net personalty, 7,247*l.* The testator left his geological and scientific pamphlets and specimens to the Liverpool University, free of duty.

MECHANICAL VENTILATION.*

THE ventilation of buildings and other enclosed spaces has passed the experimental stage long ago, but the different opinions that exist and the frequent failures to obtain satisfactory results are sufficient to show that there is still much to learn regarding the general principles upon which the various methods rely for their efficiency.

No hard and fast lines can be drawn, and no system can be generally adopted in regard to ventilation, as the conditions vary so greatly. Even the strongest advocate of natural ventilation must acknowledge that the forces upon which he relies for efficiency are uncertain in their action and often quite beyond his control, even if he disregards the constantly varying amount of dust and moisture held in suspension in the outer air. The supporter of mechanical ventilation has also many difficulties to overcome, and failure often results, though he may have a free hand and almost unlimited means at his disposal. The amount of prejudice against mechanical ventilation is very great; this is due chiefly to the numerous failures to secure a perfect change of air and complete removal of objectionable atmospheric impurities. There is a wide field open for the expert who is able to secure perfect ventilation under all conditions.

It is now well known that for a healthy existence a man must have, amongst other things, a sufficient supply of pure air, but only by breathing in the open, away from all sources of contamination, can a perfect supply be assured. In densely populated areas it is impossible to obtain (under normal conditions) air free from impurities. The composition of pure air may be taken as:—Oxygen, 209.04 parts per 1,000 vols.; nitrogen, 790.6 parts per 1,000 vols.; carbonic acid or carbon dioxide, 0.36 parts per 1,000 vols. A quantity of water vapour is also present, but the volume varies with the temperature of the atmosphere. Minute dust is an invariable constituent of natural air, and some micro-organisms are held in suspension even under the best conditions. In the respiration of animals the air on entering the lungs comes in contact with the capillary blood-vessels of the lungs, diffusion takes place, heat is generated, oxygen unites with carbon, and carbon dioxide is formed; the latter along with the surplus quantity of air, and a considerable quantity of water vapour is expired.

The expired air is deficient in oxygen, is rich in carbon dioxide and in moisture. Organic matter is also present, partly in the form of vapour and partly in suspension in the solid state. The character of the organic matter is not definitely understood, but its presence is indicated by the peculiar unpleasant odour noticeable on entering an overcrowded room directly from the outer air. The offensive nature of the atmosphere of an unventilated room may be, to some extent, due to certain disorders of the digestive organs, the excretions of the skin and the soiled clothing of the occupants.

An adult man at rest consumes in twenty-four hours about 820 grams of oxygen; the quantity required for the same period is increased to 860 grams during ordinary occupations; thus a man exhausts and renders absolutely irrespirable 5 cubic feet of air per hour.

There are other agencies tending to pollute the atmosphere of enclosed spaces—namely, the use of gas and oil for illuminating and other purposes, the decomposition of organic matter, and the dust arising from many sources, frequently of a dangerous character.

The above brief statement clearly shows that provision must be made for the removal of foul air from all occupied rooms if the atmosphere is to be maintained in a normal condition.

A perfect system of ventilation should constantly provide:—(1) A sufficient quantity of air, equal in quality to external air under the best conditions; (2) freedom from draughts; (3) freedom from dust; (4) an even temperature sufficient to prevent discomfort during ordinary occupation of the room (the air must not be stagnant); (5) an even percentage humidity. In business premises special conditions, such as an abnormal temperature and a high percentage of moisture, may be required. No system in use to-day entirely satisfies the ideal conditions.

The supply of air by mechanical means to enclosed spaces occupied by human beings may be divided into numerous sections, but it will be sufficient at the present time to refer to the following:—The extraction of foul air, the propulsion of fresh air, the supply of air without artificial heating, the supply of hot air, the extraction of dust, the regulation of humidity, and the general distribution of air from one or more centres.

In the preparation of a scheme for the ventilation of a building it is necessary to adopt a standard of purity. The maximum accommodation of each room must be accurately determined. All sources of impurity must be ascertained and carefully considered, so that the volume of air required may be provided (though it may not be constantly required). The standard can be varied to suit the conditions of each case.

It has been clearly shown that when the temperature is normal the smell of organic matter is imperceptible when the carbon dioxide due to respiratory impurity does not exceed 0.2 parts per 1,000 parts of air in excess of that contained in fresh air; but above that quantity, especially if the temperature is raised, vitiation is perceptible; 0.6 per 1,000 is therefore taken as the maximum amount of carbon dioxide admissible in a properly ventilated room.

The possibility of an increase of the temperature and an additional percentage humidity resulting from the occupation of the rooms must not escape attention.

In every case the mechanical means employed (fan or air propeller) must be sufficiently powerful to move the quantity of air necessary to maintain the standard adopted.

If the change of air is to be effected by the extraction of the vitiated atmosphere from the premises, the openings provided for the admission of air must be sufficiently numerous and situated in positions that will secure proper distribution of the incoming air. The openings should be large enough to supply the volume required at a low velocity, to prevent draughts. The air may be heated by radiators and screened by sieves at the point of entry if necessary.

The areas of the openings nearest to the extractors should be capable of adjustment, so that the volume flowing to the outlet may be drawn from all parts of the room. The retarding influence of friction must never be overlooked. In large rooms the provision of inlets and mechanical extractors in the outer walls only does not give satisfactory results; arrangements must therefore be made by the introduction of ducts to prevent the accumulation of stagnant air about the centre of the apartment.

The systematic propulsion of fresh air into enclosed spaces from one or more centres offers better means for thorough ventilation. The air being distributed through ducts and discharged at suitable positions through openings of the required size, tends to greater efficiency than results from the adoption of simple exhausting appliances. If the air is to be heated before it enters the room the ducts must be doubled, each one being sufficient separately to supply the required volume of air. This may seem to be a costly arrangement, but in large buildings it is impossible to supply air of even temperature to a number of rooms situated at varying distances from the heating centre from a single duct. The loss of heat during the transit of the air will be sufficient to prevent uniform heating of the various rooms.

In buildings ventilated and heated from single ducts the rooms near the source of heat are supplied with air at high temperature and frequently become too hot. The occupants entirely or partially close the openings, and thus interfere with the efficiency of the ventilation arrangements. In rooms a considerable distance from the heating chamber the air supplied is too cold, and the opening from the duct is closed on that account.

The double-duct system has overcome the difficulties mentioned. Each duct should be fully charged with air under the pressure required to supply the full volume to each room, so that the occupants may draw hot or cold air to maintain a desired temperature, but no interference should be possible with the regular volume discharged into the room. The occupants of apartments near the heating chamber require a small quantity from the hot-air duct and a large volume from the cold-air duct. In other rooms the opposite may be necessary, as the hot air available will be at a lower temperature if the distance from the source of heat is increased.

In almost all systems which combine mechanical propulsion with heating, serious difficulties arise regarding the delivery of air into the rooms. In all cases the size of the ducts is reduced to a minimum on account of cost; the pressure and velocity of the air which they contain is greater than would be necessary if larger ducts were provided. That causes the air to flow through the openings into each room at a high velocity.

In a well designed and properly managed system for ventilating by propulsion, the impure air of our manufac-

* Abstract of a paper by Prof. J. Radcliffe, Municipal School of Technology, Manchester, read at the summer meeting of the Institution of Heating and Ventilating Engineers at Manchester, June 22.

Digitized by Google

turing towns may be freed from a large percentage of the solid impurities it contains by screening or washing, but washing is not sufficient to entirely free the air from suspended matter. The removal of fog from the incoming air may be effected by careful management of the appliances.

In this country there is a constant variation in the quantity of moisture contained in the atmosphere. No serious attempt has yet been made to regulate the moisture in air for ventilating purposes. The percentage of saturation of the incoming air does not remain the same when the air has passed the heating chamber of a mechanically ventilated building; there is therefore a strong tendency by the heated air to take up moisture from all available sources unless some provision is made regarding it. Experiments have shown that a standard of moisture may be as easily fixed as a standard of temperature. Though the moisture added by the occupants of each room should be taken into account, reliable wet and dry bulb thermometers in each room materially assist in judging the atmospheric condition.

Unless the appliances (of all kinds) used for the ventilation of any building are intelligently designed and managed, failure is sure to be the result.

Mechanical ventilation requires a sufficiently powerful plant and careful attention by men who know the object in view, and with an interest in the success of the effort to secure a sufficient supply of pure air for those housed in the building.

Natural ventilation is desirable whenever possible, and it is suitable for many kinds of premises; but there are often occasions when the atmospheric conditions are unkindly disposed toward it, and the assistance of mechanical appliances would be very acceptable.

SURREY ARCHÆOLOGICAL SOCIETY.

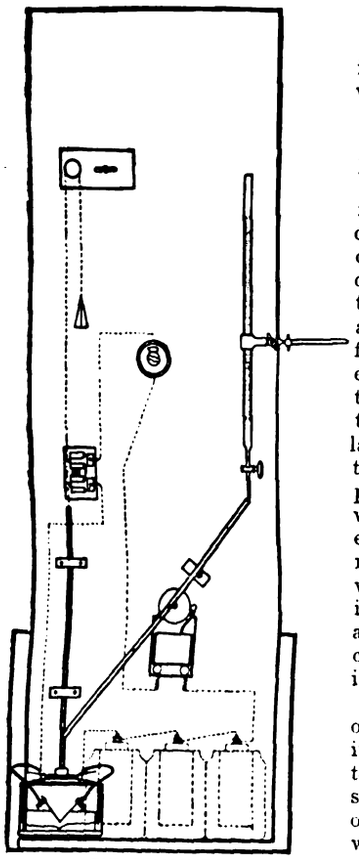
THE annual excursion of this Society for the present year was to Godalming, Dunsfold and Chiddingfold, and took place on Thursday, July 15. The members and friends assembled at Godalming railway station at 11.30 A.M., where vehicles were in waiting. As the excursion was largely attended on this occasion we would mention that this neighbourhood had been visited by the Society on several occasions formerly, and papers descriptive of Godalming will be found in the "Surrey Archæological Collections" published by the Society in Volumes IV. and VI. by the late Major Heales, F.S.A., on Godalming Church illustrated, and in Vol. VI. Mr. Ralph Nevill, F.S.A., gives an illustration of a mason's mark (quarter full size) in this church resembling a fish and a ring, very similar to that on an old tombstone in Stepney Church, which is said to be the origin of a legend in that locality called the "Fish and the Ring," and by a local tavern sign board misconstrued into the "Salmon and Ball." In Vol. III. of the "Surrey Collections" will be found an interesting article on "Richard Wyatt and his Almshouses" at Godalming, illustrated by the late Mr. Edward Basil Jupp; and in the "Herald and Genealogist" of June 1866, page 498, will also be found a still more detailed paper on "Richard Wyatt, Citizen and Carpenter," and his almshouses, by the editor of that magazine, Mr. John Gough Nichols, F.S.A. Some further "Notes on Godalming Church" will be found by Mr. Ralph Nevill, F.S.A., illustrated in Vol. VII. Also on "The Church Lands of Godalming," by Mr. S. W. Kershaw, M.A., and a list of the monuments in this church from "Manning and Bray" in this same volume, page 284. Leaving Godalming station at 11.40, carriages conveyed the members and friends to Dunsfold Church, where this building was further described by Mr. P. M. Johnston, F.S.A., architect; for a former excellent description of this interesting church by the late Mr. J. Lewis André, F.S.A., see "Surrey Collections," Vol. XIII., beautifully illustrated. The party, after luncheon at the Bricklayers' Arms Inn, Dunsfold, proceeded on foot (five minutes walk from the inn) to "Willards," an interesting half-timbered house, which was inspected by kind permission of Miss Bovill. Carriages were then resumed from Dunsfold Green to Burningfold. Here by kind permission of Mr. C. T. A. Robertson, his mansion, which still retains its early newel staircase and other features of interest were inspected, and a short sketch of its history given by Mr. H. E. Malden, M.A. Chiddingfold Church was next visited and described by the Rev. T. S. Cooper, F.S.A., the recent late hon. secretary. This extremely interesting church was visited by the Society many years ago, when a paper was read in it by the late Major Alfred Heales, F.S.A., which will be found published and printed in extenso in Vol. V. of the "Surrey Collections," and well illustrated. In his description the Major says:—"We next observe that the chancel arch is not in the middle of the east end of the nave, but on the south side; and next we shall remark the fact that the united width of the nave and aisles is within a fraction of the length of the nave, and consequently the ground occupied by the nave and aisles together is very nearly a square." In the same volume is also a paper by the Rev. L. M. Humbert, M.A., Rector, on "Notices of Chiddingfold and its Registers and Rectors." In it he says, "The marriages and burials commence with the date 1563, and the baptisms from 1573. The earliest marriage was that of Harry Peyto and Sybill Bradford, October 27, 1563."

Major Heales in his paper concludes, "The church contains no monuments whatever worth mentioning," and adds:—"Since the above was written and the locality was visited by this Society the church has been restored at great cost (chiefly by the munificence of a parishioner and member of this Society). So large a sum could scarcely have been expended without very considerable alteration in the structure, and consequently it has become doubly important to place its previous state upon record." At 4 P.M. the members and friends adjourned to the Crown Inn, Chiddingfold. This building, which dates from the fourteenth century, and is probably the oldest inn in the county, was visited and inspected, by kind permission of the proprietor. The Rev. T. S. Cooper here read a short paper on its history. After leaving the inn the party inspected, by kind permission of Dr. Nicholas F. Kendall, his house on Chiddingfold Green, which possesses some curious frescoes and other very interesting features, and permission was also obtained to visit the ancient house at the top of the Green, which was known in the fourteenth century as "Hanedmans." By the kindness of the Rev. T. S. and Mrs. Cooper, an afternoon tea was provided at Chiddingfold. At 5.50 P.M. carriages left Chiddingfold Green for Whitley railway station.

THE FILMOMETER.

AT a recent meeting of the Paint and Varnish Society at Painters' Hall, Little Trinity Lane, E.C. a description was given of the filmometer—an apparatus for testing the strength and elasticity of paint films. Mr. Cruickshank Smith, the President, mentioned the facts that led up to the presentation of the filmometer to the Society. There is an association in America known as the American Society for Testing Materials, one section of which is greatly interested in the testing of varnish films. Affiliated with the American Society for Testing Materials there is a technical and scientific society composed of members drawn from the paint manufacturers of the United States. In course of correspondence with the officials of this body some time ago, the technical director, Mr. R. S. Perry, offered to present to the Paint and Varnish Society an instrument which he has recently devised for the purpose of testing paint or varnish films in a practical way. The committee gratefully accepted the offer, and the instrument has been sent over.

There are two factors which enter into the question of the mechanical testing of paint films, namely, the strength of the film and the elasticity of the film, but as to the exact relations of these two factors and their respective influences on the durability of the paint film in service, the scientific work accomplished so far is not sufficient to enable one to express a very definite opinion. The results which Mr. Perry has been able to obtain have done something towards elucidating the problem, but before we can say much about the practical utility of the filmometer in testing paint films some practical work with it will have to be done.



Members of the Paint and Varnish Society will be able to use the filmometer after it has been properly adjusted and put in working order, in accordance with rules which the committee will frame from time to time.

The following is an illustration and brief description of the filmometer as given by Mr. Cruickshank Smith:—The instrument consists essentially of a graduated upright tube seen on the left hand of the illustration. This tube is fixed by means of sealing wax to two circular brass plates between which the film to be tested is placed, and which are clamped together while the test is being conducted. These plates are bored with a hole vertically under the orifice of the upright graduated tube. This hole measures exactly one square centimètre in area, and is circular. The upright tube is graduated in lineal centimètres, and is called the pressure tube. The burette shown on the right of the illustration is also graduated in centimètres and contains mercury, which is conveyed by the side limb of the pressure tube to the latter,

Digitized by Google

and is the means by which pressure is brought to bear upon the film under test. Above the pressure tube is fixed a wheel over which runs a thread terminating at one end in a metal rod with a float at the end. The metal rod and float extend to near the bottom of the pressure tube. To the other end of the thread is attached a counterpoise. Immediately under the openings of the metallic plates which carry the films are arranged two pieces of iron inclined at an angle of 90, and insulated by a thin piece of india-rubber. These two plates are connected up by wires with a pair of electro magnets shown above the pressure tube, the circuit being completed through an electric bell shown behind the side limb of the pressure tube and switch, shown in the centre of the diagram.

The film to be tested having been placed between the brass plates underneath the pressure tube, mercury is run into the pressure tube from the burette. As the mercury rises in the pressure tube it pushes the float upwards. When the weight of mercury in the pressure tube ruptures the paint film, the mercury falling on to the two insulated iron plates completes the electric circuit. The two small coils above the pressure tube become magnetised, and hold the metal rod firmly in position, thus enabling a reading to be taken of the height of the mercury accumulated in the pressure tube when rupture took place. At the moment when the coils become electrified, the bell rings, and the operator who is carefully watching the burette immediately turns off the stop-cock and takes the reading on the burette.

THE FILMOMETER.

Two readings are thus obtained, (1) the reading on the burette, (2) the reading on the pressure tube. The reading on the burette gives the weight of mercury necessary to rupture the film under the conditions of the experiment, while the difference between the readings of the burette and the pressure tube gives the volume due to the "sag" of the film, which is taken as a measure of its elasticity. In the case of perfectly non-elastic substances the readings of the burette and the pressure tube would, of course, always bear the same relations. Temperature is a most important factor in film testing experiments, and the experiments should be conducted at a uniform temperature. In America 70 deg. F. is the temperature that is usually adopted.

THE COMMERCIAL USES OF QUEENSLAND TIMBERS.

THE commercial uses to which the principal timbers of the colony of Queensland are put are many and various. Four varieties of ironbark—viz. white or grey, narrow-leaved, broad-leaved and red—are largely used for public works, preference being given to the white and narrow-leaved varieties. These timbers are used extensively in the building of bridges and culverts, for railway sleepers and fencing posts, and for framing, naves, spokes, poles and shafts in carriage and waggon building. Ironbark beams are of great strength, and are largely used for girders and joists of upper floors, especially in stores for heavy goods. Ironbark girders do not burn rapidly, and often stand fire when iron girders yield through the effects of the heat. Tallow-wood is strong, heavy, very durable, not easily split, and turns and planes well. It is used for bridge decking, house flooring, being peculiarly suitable for ballrooms, girders, piles and fencing posts, and especially for paving-blocks, giving even and regular wear under heavy traffic. Even better in this regard is blackbutt, a fine hardwood for house and ship building, as well as street paving. Grey gum makes excellent railway sleepers, and is used for felloes and spokes in coachbuilding. White mahogany and red mahogany are suitable for general building work, street paving, fencing and weather boards. It is exceedingly durable, and hardens greatly with age. Grey box is durable in contact with the ground, and when used for railway sleepers lasts from thirty to thirty-five years in the track. Woolly butt is used for house building, fencing and wheelwrights' purposes, and, being durable in contact with the ground and resistent to heavy traffic, is used for street paving. Spotted gum is one of the best hardwoods for bending, even when cold, and is therefore specially valuable in shipwrights' and coachbuilders' work, ship planking, decking of bridges and wood paving. Turpentine is of great durability in the ground or under water, being used for piles of jetties, &c. Blue gum is a valuable timber, with straight, symmetrical bole, and is used for upper timbers and decking in bridge work, vehicles and buildings. Messmate is largely sawn by mills for weather boards, &c., and string bark is sawn for ordinary building timber.

The Moreton Bay or hoop pine is used for the interior work of buildings, butter-boxes and packing-cases. Brown pine is also used for interior work and also for bridge, jetty and pier piles. The red cedar is a timber of great beauty; it is easily worked and very durable, and is used for furniture and cabinet-making, doors, panelling and interior fittings generally. Rosewood is also easily wrought, and is used for furniture, turnery, carving, cabinet work, mouldings, planes, window joints, house fittings and wine casks. Red bean has a finely figured grain, and is an excellent furniture wood. White beech is durable and easily worked, and is in great request for decks of vessels, furniture, picture frames, carving, flooring, house fittings, vats, casks and general coopers' work. Silky oak is also in demand for coopers' work, and it also makes handsome furniture and wainscotting. This timber is also used for butter-kegs, buckets, churns, &c., and makes good butter-boxes for the local markets. Black bean or Moreton Bay chestnut is used for furniture, cabinet-making and gunstocks. Tulipwood is highly esteemed for cabinet work, being used for door panels, dadoes and billiard tables.

GAS HEATING RESEARCH.*

(Continued from last week.)

THE room was as large as the available space allowed—viz., 9 feet by 9 feet by 9 feet, with an internal capacity, after allowing for the various articles in the room, of 710 cubic feet. Only one side was easily accessible, and in this side double doors connected with an air-tight passage gave access to the interior without danger of cold air suddenly entering. The rest of this side was fitted with shelves, both inside and outside, on which apparatus could be placed. There were two windows (14½ inches by 10 inches) immediately above the shelves, so that the apparatus could be watched from outside.

Air was admitted through movable panels 10 inches square at the top and back of the room; and the products of combustion were carried away through a square flue placed at the opposite side of the room near the ceiling. This flue was connected with the chimney of the outer room—an ordinary kitchen chimney. As it was important that this flue should be quite air-tight, the inner lining was made of galvanised sheet iron. So that the combustion products might be drawn away if required at a uniform rate a small electric fan was used and fitted exactly into the outer end of the flue. This could be run at either a high or low speed. This, as well as the electric lights within the room, was controlled by switches from outside.

The gas supply pipe passed into the room through a panel, and was directly connected to the test-meter, standing on a shelf outside the room. This in its turn was connected through a Stott's governor with the house supply meter.

The flue inside the room was made of sheet copper, wrapped with asbestos board in order that there should be as little loss of heat as possible from the flue gases before

* Extract from report of the Gas Heating Research Committee appointed by the Institution of Gas Engineers in conjunction with the University of Leeds, and consisting of Messrs. John Bond, J. H. Brearley, and Charles Wood, in co-operation with Professors Arthur Smithells (Chairman), William A. Bone, and Julius B. Cohen, of the University of Leeds, and Mr. E. W. Smith (Research Chemist), to the Institution of Gas Engineers, at their Annual Meeting held in London during June 1909.

Digitized by Google

they passed into the kitchen flue, outside the experimenting room. The flue left the room by means of a hole 8½ inches square, 8 feet 4 inches from the ground. Its cross section dimensions were 6 inches by 4 inches, and at the point where it left the room its cross-sectional area might be reduced either to 4 inches by 4 inches or 3 inches by 3 inches. At this point, too, an electrical resistance thermometer was brought into use—this being connected with a Callendar recorder, erected in the main buildings. Arrangements were made that samples of gases might be drawn from the room from immediately above the stove, and from the flue near to the thermometer. This was done by means of aspirators, in which the volume of gas abstracted could be measured.

Method of Estimating the Rate of Air Change in the Room.—The chemical method was adopted for the estimation of the rate of air change in the room as being likely to prove the most accurate for the work in hand. The mode of procedure was as follows:—

1. A determination was made of the carbon dioxide contents of the outside air in parts per 10,000 (Pettenkofer method, modified).

2. A sample was taken extending over the whole time occupied in doing the ventilation experiments (fifteen to twenty hours) of the gases passing up the flue, and the carbon dioxide contents determined in parts per 10,000.

3. The gas-rate in cubic feet per hour was accurately determined and reduced to 0 degs. C. and 760 mm. pressure, dry.

4. A sample of the gas burnt was abstracted from the main before entering the test meter, during the whole experiment. This was exploded with oxygen in a "Bone and Wheeler" gas analysis apparatus, and the amount of carbon dioxide formed from the combustion of a cubic foot of the consumed coal gas estimated.

From (4) and (3) was estimated the volume of carbon dioxide (at 0 deg. C. 760 mm. dry) passing into the flue per hour. Then if (1) = x; (2) = y; (4) = z; and if the volume of air passing up the flue per hour equals "v," then

$$v = \frac{z}{y-x} \times 10{,}000.$$

Carbon Dioxide Determinations.—Pettenkofer's method was employed with the modifications proposed by Letts and Blake.* These consisted (1) in coating the inside of the sampling vessels with paraffin wax to prevent the glass being attacked by baryta solution, and (2) carrying out the titration in a vacuum. A further modification consisted in having a soda lime tube fitted to one of the holes in the corks of the sampling bottles, and also a three-way glass tap. The same was done with the titration flask. By this means atmospheric carbon dioxide was prevented from entering these vessels should the gases contained contract owing to a fall of temperature in taking them into the laboratory, which remained fairly constant between 56 degs. Fahr. and 60 degs. Fahr. The results obtained by this method were checked by a gravimetric determination, by drawing a sample over calcium chloride, sulphuric acid, caustic potash, and soda lime. They were not found to differ seriously. The samples of flue gases were always analysed gravimetrically.

Carbon Monoxide Determination.—The flue gases were also analysed for carbon monoxide in most experiments, as were also the gases abstracted from immediately over the stove. The method depending on the liberation of iodine from iodine pentoxide by means of carbon monoxide, and the formation of carbon dioxide, was adopted.

$$5\,CO + I_2O_5 = I_2 + 5\,CO_2.$$

The amount of change was estimated colormetrically by absorbing the iodine in chloroform and comparing the solution with equal volumes of standard solution. This method was open to slight error, as the iodine pentoxide was liable to be reduced by other constituents in the sample than carbon monoxide, as, for example, by formaldehyde, the presence of which in the products of combustion was most probable. The quantities of carbon monoxide found in all cases were so small that, assuming the whole of the change was caused by this gas, the figures are sufficiently convincing to show that during the course of these experiments only negligible quantities were formed, if any at all.

Hygrometric Measurements.—Wet and dry bulb thermometers, previously tested, were placed inside and outside the room in order that the percentage saturation of the inner and outer air might be determined. Glaisher's tables were used. Both hygrometers could be read from outside the room.

Sulphur Determinations.—The Gas Referee's apparatus was open to two likely sources of error—firstly, in the incomplete oxidation of the sulphur, and, secondly, by contact of the hot parts with rubber containing sulphur. An apparatus was designed in which all the connections were ground glass joints, and in which the combustion products were led over hydrogen peroxide solution and cooled by passing through a water-cooled condenser tube. The results obtained were higher than those got by the Gas Referee's apparatus.

(To be continued.)

* Cf. *Proceedings of the Royal Society of Dublin*, 1900, p. 107.

COMPETITION RESULTS.

THE Bootle Town Council at their last meeting approved the education committee's recommendation that the plans selected for the proposed new Balliol Road Council school should be provisionally adopted. On the sealed envelope being opened the successful architects were announced to be Messrs. Medcalfe & Medcalfe, Moorfields, Liverpool.

The plans of Messrs. Thos. Bower & Edleston, Bank Chambers, Nantwich, have been selected for the Nantwich cottage hospital to be erected at Henhill. The hospital will, it is estimated, cost 2,142*l.*

Mr. F. Q. Farmer, architect, Stalybridge, has been awarded the first premium of 15*l.* 15*s.* in a competition for a Council school to accommodate 850 children at Mossley, Lancs. The second premium of 5*l.* 5*s.* goes to Messrs. J. Gunson & Son, architects, Manchester.

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *American Architect*, continuing its account of architecture in the Southern States, gives an account of "a day at Williamsburg," an old town of Virginia, "whose whisperings of a mildly frivolous yet intense past have not been drowned in the roar of modern progress," whose courthouse is ascribed to Sir Christopher Wren, and whose buildings are practically all of the "Colonial" period. As a contrast, and a not altogether pleasing one, is illustrated a modern house in Atlanta, which for incorrectness of grammar without force of diction would be hard to beat. A luxuriously enriched alteration to a New York house for E. F. Whitney, Esq., is also illustrated.

La Construction Moderne illustrates details of the interior of the Bureau de Poste of the Maison Dorée at Paris, of which Mr. R. Binet is the architect, and which is a curious mixture of modern Parisian architecture and reminiscences of French Gothic. It is amusing to note that the sculptors, MM. Moreau-Vauthier & Guillot, symbolise London in the guise of a modern lady habited in winter walking costume on a windy day, with muff and boa and a "Merry Widow" hat.

Deutsche Bauzeitung is occupied with a burning question, the erection of a new police building on the site of the old Augustinian church in Munich, and the competition designs for this new building are illustrated, with a discussion for and against the retention in whole or in part of the old buildings. The first prize design is by Messrs. Delisle & Ingwersen, of Munich; the second by Messrs. Hessemer & Schmidt; and two third prizes are awarded to Professor Dr. Theodor Fischer, of Munich, and to Messrs. Scholer and Professor Bonatz, of Stuttgart.

Innen-Dekoration illustrates the exterior as well as the interior of the Märkische Museum at Berlin, designed by Stadtbaurat Ludwig Hoffmann, in which archæological correctness is adopted with the view of fitting the casket to the jewels it contains. This leaves little room for a residence at Grunewald and for furniture designed by de Feure, of Paris, in which latter simple forms with varied inlays are excellently treated.

Der Architekt gives a continuation of Professor Adolf Hölzel's article on the use of the executive arts in connection with architecture, and now treats of wall painting with special reference to the decorations of the so-called "Pfullinger Hallen," a building comprising concert rooms and theatre. The remarkable Karl Borromäus fountain at Vienna is excellently illustrated, the architect being Josef Plecnik, and the sculptor Josef Engelhart. Two designs by Franz Matouschek, of Budapest, are noteworthy, the one for a Jewish synagogue at Trieste, the other for an artist's house at Budapest.

Digitized by Google

Der Profanbau brings before us some of the modern castles erected from the designs of Professor Bodo Ebhardt, of Grunewald, Berlin—namely, Gröditzberg, Landonvillers, Die Marksburg am Rhein, Altenburg, which are admirable reproductions of the spirit and forms of old German fortified houses.

The *Engineering Record* (New York) describes the construction of the Boston Safe Deposit and Trust Company's building, a new "steel-cage" structure occupying an approximately rectangular area about 122 feet by 125 feet, with ten floors above the street level and two below. An account is given of a difficult piece of underpinning work to a leaning chimney of reinforced concrete 108 feet high in Jersey City.

Correspondence

[*The Editor will not be responsible for the opinions expressed by Correspondents.*]

Architectural and Topographical Society.

SIR,—May we venture through your columns to appeal for help in a work which has been described as one of national interest—namely, that of making complete historical records of the ancient buildings of these islands, from the introduction of civilisation to the year 1800, which has been undertaken by the Architectural and Topographical Society?

The need for such a work has been admitted on all sides, and ought to have been undertaken long ago, for it is now almost impossible, after a century or more of destructive so-called "restoration," to obtain exact information as to the previous condition of much of our historic architecture.

Although this Society is unable to act in any manner directly calculated to prevent such destruction, yet by recording precisely and in detail the present state and the nature of the buildings and the monuments, it is able to some extent to counteract the effects of such vandalism, and owing to the low rate of our subscription (*i.e.*, 10*s.* 6*d.* per annum), and the consequent accessibility of our publications to all, there is a potential educational value in our work.

These considerations form an overwhelming argument in favour of so low a subscription, but it is obvious that the expenses of printing and publishing records of buildings with sufficient illustrations fully to explain the text must be practically the same whether the circulation be 200 or 1,000; therefore the ratio of revenue to expenses must, until the subscription list approaches the latter figure, be too low to make the Society self-supporting.

On these grounds alone we might venture to trouble you, and through you the public, but we would at the same time lay additional stress on the following points, *i.e.*:—

1. Since the foundation of the Society, rather more than twelve months ago, complete accounts of the buildings in seventeen parishes have been published.

2. The value of the work has been endorsed by the fact that many of the leading societies interested in this subject are now subscribing.

3. There are at present some twenty parishes partly completed, in addition to those already published, and several more are definitely promised. The fact that the Society can obtain work of this nature entirely gratuitously shows how greatly the need for such records is felt by those who have expert knowledge of the subject.

4. The recent appointment of Royal Commissions to make an inventory of the ancient monuments of England, Scotland and Wales shows that the State appreciates the need for such work; and by its terms of reference the Commission is only intended to make an inventory, and does not in any way cover the ground of this Society's labours.

5. The other part of the Society's work, which includes the collection of carefully made record drawings, notes and photographs, &c., is progressing, and a considerable number of such records are now either promised or are already in our possession.

6. All the work done for the Society is purely honorary, therefore its funds are expended entirely on the work and not in any way upon the workers.

7. A large sum of money is subscribed annually towards the furtherance of similar work in the ancient world of Egypt and Rome, and it would be unworthy of our national traditions should researches into the history of our own country fail for want of funds.

The minimum sum of 500*l.* is required to ensure the effective continuation of the work of the Society until such time as the annual subscription list shall be equal to the necessary disbursements; a further contribution would enable the rate of progress to be made more consonant with the amount of the work to be done.

In conclusion, we would appeal to all who take an interest in the history of their country to help the work in some degree. Subscriptions and donations should be made payable to the Society, and crossed "London and County Bank."

All communications should be addressed to the offices of the Society at 33 Old Queen Street, Westminster, S.W.

Donations will be treated as subscriptions, and donors of half a guinea or more will receive the record for the current year, whilst those of seven guineas and upwards will be entered on the Society's list of life members.

Coal Smoke Nuisance.

SIR,—Your report of the meeting of the Institution of Gas Engineers is lying before me, in which reference is made to the great influence that improved types of gas cooking and heating stoves are likely to have in the near future upon the purifying of the air. As mentioned in your summary of the address, all gas companies produce coke, but it is sometimes seen that these gas companies have difficulty in disposing of their coke productions at a remunerative figure. Undoubtedly it is in the interest of all gas companies to increase the market for their gas rather than seek markets for their by-products, such as coke, but several gas companies have, with praiseworthy foresightedness, introduced in their towns stoves constructed specially to burn coke, and it has been found that many people who have objections to the use of gas stoves have used with readiness stoves to burn coke, because of the well-known fact that coke is cheaper than coal.

During last winter I had a stove which I kept burning night and day continuously through six months. It was heating a room of about 3,000 cubic feet at an average cost of 1*s.* 6*d.* per week, and required replenishing with broken coke not oftener than twice every twenty-four hours.

I think if the public were educated to appreciate the advantages of burning coke in a closed stove, the open-fire grate would soon be a thing of the past.—Yours faithfully,

HERBERT TEELING.

Heriot Hill House, Canonmills, Edinburgh:
July 8, 1909.

Influence of Material.

SIR,—Whilst interested in reading Mr. Aitken's reply to my letter on proportion in architecture, I find nothing in it to modify my views. Is it not, in the first place, apparent that it is possible to triangulate every façade after some fashion, and that the mere fact of so triangulating does not connote studied proportions? Further, the idea as to "correcting imagination by the application of geometry" presupposes a fundamental artistic value in the latter science—a supposition that is absurd. Mr. Aitken continues:—"Imagination alone may lead to eccentricity." *Good* imagination may be safely trusted to its own guidance; and feeble imagination, even conjoined with geometrical rules, will never produce fine art.

Again, we are told that of two Ionic buildings one is triangulated with 60° and 30° and the other with 45°, both of them admittedly fine buildings. How does this help Mr. Aitken's argument as to the Parthenon, "which, *when compared with similar buildings of its style*, holds the field for beauty of proportion?" The italics are mine.

Mr. Aitken's suggestion as to coincidences and accidents deserves comment. When you do not obtain two buildings in a style agreeing in triangulation, there is no coincidence; and it is only on obtaining numerous according "accidents" that the latter become coincidences and may merit consideration as rules. The "method that was apparently employed

Digitized by Google

to fix the diameters of columns both Classic and Mediæval" does *not* merit serious consideration, being one that, in the language of triangulation, is equivalent to going two sides of a triangle to reach the further point, instead of negotiating the hypothenuse.—Faithfully yours,

49 Queen Victoria Street, E.C. PERCY L. MARKS.

Middlesbrough Library Competition.

SIR,—We have now received the following reply to our letter of the 30th ult. from the Royal Institute of British Architects in regard to the above competition:—

"July 9, 1909.

"Middlesbrough Library Competition.

"Dear Sirs,—I am desired by the Council of the Royal Institute to inform you that your letter of June 30, addressed to the President of the Royal Institute, has been laid before them by the President, and as a result of their inquiry into the subject of your letter I am to inform you that the decision of the competitions committee has the approval of the Council.—Faithfully yours,

(Signed) "IAN MACALISTER,
"*Secretary.*

"Messrs. Hoskins & Brown, Kitching & Lee, and W. H. Bourne, Houndgate Chambers, Darlington."

We now propose taking counsel's opinion as to the position of the competitors in this competition.

Would those architects who signed the memorial, who have not yet forwarded the 5*s.* asked for, for preliminary expenses, kindly do so at once.

We should also be pleased to receive subscriptions from any other architect who sympathises with the object in view.

Any future action, after counsel's opinion is obtained, will be left to the subscribers.

Whatever counsel's opinion may be, architects will at least have the opportunity of knowing their legal position in future competitions.—Yours faithfully,

HOSKINS & BROWN,
KITCHING & LEE,
W. H. BOURNE, A.R.I.B.A.

Houndgate Chambers, Darlington: July 12, 1909.

The Improvement of London.

SIR,—The very interesting accounts which have just been published of the enterprise of Mr. Charlton Humphreys, in acquiring the freehold of the Knightsbridge estate, must cause those who have an eye for the improvement of London to see visions. One of the first possibilities to suggest itself is the transfer of St. George's Hospital from its extremely valuable, but, for the purposes of a hospital, most unsuitable site, to the quiet situation of Trevor Square.

Such a change would, at one stroke, advantage a great public charity and make available the unique site at Hyde Park Corner, in many ways the most conspicuous in the metropolis, for an opera house, or other building of like character.

London is indebted to the private enterprise of her great landlords for the squares, which are some of her chief adornments. May the private enterprise of Mr. Charlton Humphreys be equally beneficent.—I am Sir, yours faithfully, MARK H. JUDGE.

7 Pall Mall: July 10, 1909.

Guild of Architects' Assistants.

SIR,—Many thanks for the publication of my letter *re* the Guild of Architects' Assistants, but I should like to point out what appears to be a printer's error. In the third paragraph from the bottom the word "decreasing" competition appears instead of "increasing," which spoils the sense of the sentence.

I hope that in my letter I had not made that mistake.

In any case, perhaps you would kindly draw attention to this in your columns, and oblige, yours faithfully,

HERBERT COX.

10 Mecklenburgh Street, Mecklenburgh Square, London, W.C.: July 14, 1909.

SIR,—The letter from Mr. Herbert Cox in your issue of the 9th inst. is, if I may say so, admirable good sense. But in the third paragraph from the end the logic seems somewhat at sixes and sevens, unless, as I surmise, there is an error in one word. Surely Mr. Cox meant to say "increasing competition between assistants," not "decreasing." Unless this be so, the paragraph seems to be perilously near nonsense. Perhaps you or Mr. Cox will clear this up.

The Guild appears to be a successful attempt to do what has been tried many times before without success, and if assistants realise that their interests are clearly served by joining, and thus supporting each other, its success is assured. At the same time there is no reason for thinking that the interests of principals are opposed to those of assistants who are members of the Guild, and nothing but value to both should accrue when the Guild is on the high road to success if its management keep the common interest in view.—Yours faithfully,

E. GODFREY PAGE, A.R.I.B.A.

2 Old Serjeants' Inn, Chancery Lane, E.C.

[We have looked up Mr. Cox's letter, and find that he wrote "increasing," and the printer has made it "decreasing."—ED.]

GENERAL.

The Wolverhampton Town Council have decided to confer the freedom of the borough upon Sir George Hayter Chubb.

Stoke Park, the former home of the Penn family, has been altered to form the club house of the Stoke Poges Golf Club, and it was formally opened on Monday last. The house was originally a square red-brick eighteenth-century building, the successor to the old Tudor manor house still standing in the park, but it has been enlarged from time to time, and some fine reception-rooms, quite suitable for the purposes of a club, have been added. The present alterations have been confined mainly to the bedroom floors and the basement, and to the building of a caddie master's house, the exterior with its symmetrical wings and central dome, and the long columned loggia facing the terrace being left quite unchanged. The gardens, which are of the landscape type, are very fine of their kind, and the park forms an ideal golf course. The general contract has been carried out by Messrs. Shoolbred & Co., the hot water and cooking apparatus by Messrs. Wilson & Smith, the drainage and other sanitary work by Messrs. Fleming & Co., and the electrical plant and wiring by Messrs. F. A. Glover & Co. The architect for the work was Mr. Arthur Keen, F.R.I.B.A.

The West Riding Finance Committee have arrived at the conclusion that the work under the Education Acts is sufficient to absorb the entire time and attention of a competent architect. They therefore recommend that the West Riding architect's department be reorganised and divided into two sections, each to be under a competent architect, one to take charge of the work of the education committee, the other to take the rest of the work; that the salary of Mr. J. Vickers Edwards, the West Riding architect, be reduced from 1,500*l.* to 1,000*l.* per annum as from January 1, 1910, provided he agrees that he will not make any claim for compensation by reason of such reduction, and that an architect be appointed to carry out the work of the education committee at a salary not exceeding 500*l.* a year. The above recommendations were discussed for two hours on Wednesday, and the County Council finally decided that Mr. Vickers Edwards should be asked to retire, and that the finance committee should be authorised to fill up the vacancy at a salary of 700*l.* a year.

The Royal Institute of Painters in Water-Colours at a general meeting held last week elected Sir James D. Linton president in place of the late Mr. E. J. Gregory, R.A.

The Volunteer Workers who are excavating on the site of the ancient abbey at Bardney, near Lincoln, have made further interesting discoveries. The west front of the church, including the west door, with beautiful carving, is now bared, and a stone in memory of the twenty-seventh abbot of Bardney has been brought to light. This measures 8 feet 4 inches by 3 feet 8 inches, and is in splendid preservation. A figure of the abbot is delicately carved in the centre, and there is an inscription stating the time of death, October 1, 1508, &c. The members of the Royal Archæological Society are to visit the abbey in the latter part of this month.

The London County Council in March 1908 decided to award annually three scholarships tenable for three years at the School of Art Woodcarving, South Kensington, subject to regulations which provided that the scholarships should not be awarded upon a competitive examination, but by nomination upon consideration of the candidate's general capacity and manual and artistic skill. The number of candidates has increased this year, and it seems probable that in future years it will still further increase. In order to limit the number of candidates to be interviewed, it is recommended that they shall be required to take an examination in drawing and modelling, either from common objects, plant form, or from ornament, flat copy or cast, and, if thought advisable, only those candidates who attain a certain standard in the examination need be interviewed.

FORTHCOMING EVENTS.

Saturday, July 24.

Architectural Association. Third Summer Visit to "Ardenrun," near Godstone, Surrey (a house by Mr. Ernest Newton).

Royal Archæological Institute. Annual Meeting at Lincoln, July 23 to July 30.

Town Planning and Housing Exhibition, Hampstead. Lecture on "The Conditions of City Development," by Professor Patrick Geddes.

Monday, July 26.

Builders' Benevolent Institution: Annual General Meeting and Committee Meeting.

Tuesday, July 27.

Kent Archæological Society: Annual Meeting at Museum Buildings, Maidstone, July 27 and 28.

Wednesday, July 28.

Town Planning and Housing Exhibition: Lecture on "Architecture and Town Planning," by Mr. W. Woodward, F.R.I.B.A.

Saturday, July 31.

Architectural Association Camera and Sketching Club Summe Continental Excursions: Caudenbec and District, July 31 to August 7.

STUDENTS' DRAWINGS AT THE ARCHITECTURAL ASSOCIATION.

THE drawings now on view at the Architectural Association, Tufton Street, Westminster, are illustrative of part only of that body's teaching, being practically a sample of the work that is done in the studio, whether in the day school or in the evening school. It is a pity, and it reflects discredit on the Association, that the drawings are not more carefully hung, particularly with regard to the work of the evening school. No sort of system is adopted, and it is most irritating to a visitor who wants to follow the progress of the students during their year's work to find drawings hung in a haphazard fashion. To begin with, it is a matter of the utmost difficulty to find out who is the author of any particular drawing. Nine times out of ten the author's name is covered up, drawings being pinned over one another as if the A. A. could not afford an extra eighteenpence for another gross of drawing pins. Then one finds that one man's drawings for a particular subject are interspersed with somebody else's, not necessarily even of the same subject. It looks as if the masters had selected a certain number of drawings and left it to the most junior clerk in the office to hang them, which he did haphazard and as they came.

Obviously there are two systems either of which might have been satisfactorily adopted for arranging the drawings. We might have had each student's work by itself shown chronologically in the order of its production. Then we should have been able to see the value of the instruction given, and observed how each man had made progress during the session, a useful criterion of the value of the instruction and the receptivity of the individual for that instruction. On the other hand, the drawings might have been arranged under subjects, then we might have estimated the comparative merit of each student's work in the treatment of each particular problem, and we might have expressed our personal opinion as to the correctness or otherwise of the awards of the prizes. We trust that the award of prizes was made before the drawings were hung, for we defy anyone to make a just estimate of the work done by the students from the drawings as exhibited. Accordingly we decline to express any opinion as to the justness of the awards beyond this, that in several instances in particular subjects we have seen better designs submitted than those of the prize-winners. We quite recognise that in awarding prizes for a session's work in a school, quantity counts to some extent as well as quality, so that a student who has made six designs worth five marks each stands higher than one who has done three designs worth nine marks each, although the latter is far the better man.

The predominant impression that we gather from a very careful inspection of the drawings exhibited is that effective prettiness in draughtsmanship is the chief aim in the A. A. studios. It looks as if the students were encouraged tacitly, if not openly, to think more of tricky drawing than of excellence in the real qualities of design. In a school of architecture this is wrong, albeit it may turn out men who although not great architects may catch clients, especially lady clients. The A. A. students, unless they advance beyond what they are now learning in the studios, will not win competitions, but with a good connection and a plausible manner they may make a decent practice, for there are plenty of people in Great Britain who cannot appreciate good design but may be caught by a pretty drawing. Hence the A. A., on its present lines, is turning out those who with luck and sufficient opportunities, may become successful practitioners, but will never be great architects.

In the work of the day school, which is classed under first year and second year, we have presumably that produced by the best students from amongst those who have come straight from school to professional study. The method of instruction is well arranged: first, the embryo architect is taught to make measured drawings of the studio in which he works, and freehand drawings of its furniture; then he makes a complete set of drawings from buildings already carried out by good architects of our own time, and studies of some of the great works of antiquity. In his vacations he is encouraged to make measured drawings of old work. We were pleased to see an isometric drawing of a Greek Ionic cap; such an exercise is worth dozens of reproductions of elevations of the orders from MAUCH or SPIERS. But even in the work of first-year students, the merest tyros in architecture, there is a striving after the pretty drawing, after tricks of draughtsmanship whether in pencil or in colour. Perspectives do not correctly show the building as it is in the plans and elevations, but they are pretty. In the second year a day school student begins to design and exercises himself on such academic subjects as a Greek Agora in Doric style and a Roman bath in Ionic, as well as more modern subjects, as a group of labourers' cottages. A Roman hall and a domed church were also set for design, the latter rather an ambitious subject, though well tackled by Mr. F. A. CROUCH in particular. Still the fatal prettiness of draughtsmanship is more evident than solid excellence of design. Details

Digitized by Google

of construction are also studied partly from actual observation.

The end of session test, a "Study for a Country Cemetery Entrance Lodge," affords a means of judging how far the students have learnt to design and what they can effect when left to their own devices and deprived of the criticism, suggestions and assistance of a master, which we understand goes so far as the inclusion of actual handiwork by the instructor on a student's drawing. The result is not very satisfactory. The study placed first, that by Mr. H. B. CHISHOLM, is modest and not a very remarkable production for five days' work. It is, however, the best. The study placed second, which is by Mr. S. J. H. PRYNNE, is more ambitious but less successful. Ambition is not a bad fault in a young aspirant. "Who aims the sky, although he do not hit his mark, shoots higher far than he who aims a tree." Of the studies receiving honourable mention we can but say that the drawing is better than the design.

Coming to the work of the evening school, whose students are presumably those engaged in architects' offices, either as pupils or assistants during the day, and possibly of more experience than those in the day school, we cannot fail to notice a better quality than in the work of the latter, noticeably in the second year, where we find at least in one instance the same subject treated. As we have already said, owing to the unsatisfactory manner in which the drawings are hung it is hopeless to attempt any fair comparison of the work of various students, or to estimate the advance they have made during the session. All that we can do is to point out some of the good work shown. In the second year the drawings for a village church, by Mr. H. D. KIDD and Mr. A. T. HARDMAN, are both deserving of mention. In the third year work there are designs for the re-arrangement of the Marble Arch and its surroundings that put to shame the scheme actually executed. The work of Mr. P. D. HEPWORTH, who wins the scholarship, is good, particularly his design for a country house, whilst Mr. O. F. HILL'S school memorial hall is well worthy of notice, although that gentleman's name does not appear in the prize list, even to the extent of honourable mention. Similarly in the fourth year, although the work of Mr. C. A. FAREY, who is placed first, is distinctly excellent, Mr. SWINDELL, who is unmentioned in the list of awards, has produced commendable designs for a music room and for a riverside factory and warehouse. Draughtsmanship being as we have pointed out the goal of the A. A. studios, we should mention as striking examples Mr. A. D. ROBINSON'S detail of an Ionic cap, Mr. GORDON HAKE'S coloured perspective of the riverside warehouse, and Mr. PRYNNE'S drawing of a stone panel.

The list of awards in the schools is as follows:—

DAY SCHOOL.

FIRST YEAR AWARDS.—Book prize for first place in history test paper and general excellence in this subject, E. L. Apperly. Book prize for first place in construction test paper and general excellence in this subject, E. L. Apperly and R. C. Stevenson, equal. Geometry, first place T. F. Ford. Physics, first place C. Rowntree. A.A. sketch book for first place in freehand drawing, A. E. Maxwell. Prize for first place in perspective drawing test, E. L. Apperly. *The Studio Prize.*—Best portfolio of drawings made during session, R. C. Stevenson. Recommended for special prize for excellence, A. E. Maxwell. Hon. mention, E. L. Apperly, T. F. H. White, F. P. Spooner, C. Rowntree, L. M. Yetts and T. F. Ford. Authors of drawings selected for school portfolio, R. C. Stevenson, A. E. Maxwell, T. F. H. White, L. M. Yetts, E. L. Apperly, and T. F. Ford.

SECOND YEAR AWARDS.—Travelling studentship 15*l.*, for studio and lecture work during session 1908-09, holiday work and general progress, F. A. Crouch; specially commended, A. G. Butler; hon. mention for general progress during session, E. S. A. Baynes, C. W. Rogers, J. O. B. Hitch, B. P. Gaymer, J. A. Cheston, E. W. Mountford. *End of Session Test.*—Subject, "Study for a country cemetery entrance lodge," award made by Mr. Henry Tanner, President A.A. Study placed first, No. 5, H. B. Chisholm; study placed second, No. 17, S. J. H. Prynne; hon. mention, No. 14, L. D. Martyn; Nos. 21 and 20 equal, C. W. Rogers and B. Gaymer. Drawings selected for presentation to school portfolio, F. A. Crouch, A. G. Butler, E. S. A. Baynes, C. W. Rogers, J. O. B. Hitch and H. B. Chisholm. Students recommended for the Association two years' course certificate, E. S. A. Baynes, A. G. Butler, J. A. Cheston, H. B. Chisholm, F. A. Crouch, B. P. Gaymer, J. O. B. Hitch, L. D. Martyn, E. W. Mountford, C. W. Rogers, S. E. Shurmur and R. Talvalker.

EVENING SCHOOL.

SECOND YEAR.—1, D. J. S. Dawson, scholarship, 15*l.* 15*s.*; 2. H. D. Kidd, book prize, 2*l.* 2*s.*; 3. H. V. C. Curtis, master's prize for hardest worker; hon. mention, G. F. Rowe and A. T. Hardman.

THIRD YEAR.—1, P. D. Hepworth, scholarship, 15*l.* 15*s.*; 2. H. E. Moss, book prize, 2*l.* 2*s.*; 3. C. Castelow, master's prize for hardest worker; hon. mention, E. J. Hatherall, H. A. Thomerson, B. P. Collin, P. M. Andrews and H. A. Gold.

FOURTH YEAR.—1, C. A. Farey, scholarship, 15*l.* 15*s.*; 2, B. F. Matthews, book prize, 2*l.* 2*s.*; 3, R. M. Pigott, master's prize for hardest worker; hon. mention, L. K. Hett, G. D. G. Hake, A. D. Robinson, G. F. Clarkson and R. W. Cable.

LECTURES.

FIRST YEAR.—*Elementary Construction.*—1, Norman Keep, book prize; 2, R. Topham; 3, C. J. McCausland. *Plane and Solid Geometry.*—1, G. H. N. Inman, book prize; 2, C. J. McCausland; 3, Norman Keep. *Preparatory Physics.*—1, D. J. S. Dawson, book prize; 2, R. Topham; 3, A. L. Lucas.

SECOND YEAR.—*Intermediate Physics.*—1, F. A. Crouch, book prize; 2, R. Talvalker; 3, H. Burch. *Grecian and Roman Architecture.*—1, G. M. Eaton and R. N. Jackson, book prize; 2, F. A. Crouch; 3, C. W. Rogers. *Early Christian and Gothic Architecture.*—1, C. W. Rogers, book prize; 2, F. A. Crouch; 3, J. A. Cheston. *Renaissance Architecture.*—1, R. N. Jackson, book prize; 2, C. W. Rogers; 3, J. O. B. Hitch.

THIRD YEAR.—*English Architecture.*—1, P. J. Adams, book prize; 2, W. J. Durnford; 3, B. P. Collin. *Advanced Physics.*—1, W. J. Durnford, book prize; 2, R. A. Walter; 3, W. Roberts. *Materials.*—1, P. J. Adams, book prize; 2, W. J. Durnford; 3, R. A. Walter. *Drainage and Water Supply.*—1, H. A. Thomerson, book prize; 2, W. J. Durnford; 3, C. J. Newberry.

FOURTH YEAR.—*Ventilation, Lighting, and Heating.*—1, G. F. Clarkson, book prize; 2, H. A. Ross; 3, R. M. Pigott. *Iron and Steel Construction.*—1, G. F. Clarkson, book prize; 2, W. C. Rhodes; 3, C. F. Butt. *Advanced Construction.*—1, G. F. Clarkson, book prize; 2, B. F. Matthews; 3, R. M. Pigott. *Architectural Features.*—1, G. F. Clarkson, book prize; 2, R. A. Duckett; 3, L. K. Hett. *Professional Practice.*—1, G. F. Clarkson, book prize; 2, W. C. Rhodes; 3, A. R. Gunn.

NOTES AND COMMENTS.

ON Wednesday last the Royal Institute at a special general meeting confirmed the resolution empowering the Council to acquire the interest in the galleries at the rear of its present premises, an important step that will be beneficial undoubtedly to the work of the Institute and the comfort of its members. These premises are not ideal, but it is worth while sacrificing some of the ideal for the advantage of remaining at 9 Conduit Street, and the difficulties of finding better premises or the opportunity of erecting better premises anywhere near the present centre are inconceivable to anyone who has not had experience in trying to solve the problem.

ON the same evening the Royal Institute completed its task of revising the bye-laws to suit the new Charter and the new conditions. The poll, as was to be expected on the point of limiting the period of service of ordinary members of the Council, confirmed the resolution of the meeting of June 11. The remaining bye-laws, referred back to the Council, were passed after some discussion practically as printed, the only important amendment being that the period within which, after a resolution has been carried at a special general meeting, a poll can be demanded has been extended from seven to fourteen days, with the avowed object of allowing provincial mem-

Digitized by Google

bers of the Royal Institute to demand a poll, if they should so desire. It says much for the willingness and desire of London members that provincial members should not be debarred more than is inevitable from the affairs of the Institute that such a resolution should have been unanimously carried in a meeting of London members. In truth, the Londoners would like the provincials to be enabled as far as possible to take not only an interest but a share in the decisions of the Royal Institute.

THE Forms of Declaration were fully discussed, and some of the practical difficulties in the alterations proposed by the Council with the very laudable intention of setting a higher standard of professional ethics were so strongly appreciated that by a succession of whittling amendments the declarations now remain practically as they were before the new Charter. Nothing therefore now remains but the formal confirmation of the bye-laws as passed and their approval by the Privy Council for the new Charter and bye-laws to come into operation.

THE proposed St. Paul's Bridge has met with too great an opposition for the present in the Court of Common Council, and the recommendation of the Bridge House Estates Committee has, by a small majority, been referred back for reconsideration. We cannot see that the opponents of the new bridge have any very strong arguments on their side, their main contention being that the City ought to wait to see what will be the effect of widening Blackfriars Bridge and should improve the gradients and approaches to Southwark Bridge. But the widening of Blackfriars will only suffice to enable it to carry the tramway lines, and we know from the position of our office that there is often far more traffic trying to get to Blackfriars Bridge than it can conveniently carry. It seems to us, too, that an improvement in Southwark Bridge, if effectual in attracting traffic, will only bring that traffic into contact with the east and west stream, augment these, and congest still more than at present the western part of Cannon Street.

THE opposition to the proposed removal of Sir ROBERT GEFFERY'S almshouses in Shoreditch has little ground of support from any architectural interest in the old buildings, but as a matter of preserving an open area of about an acre in a crowded district there is much to be said in favour of the retention of the present establishment.

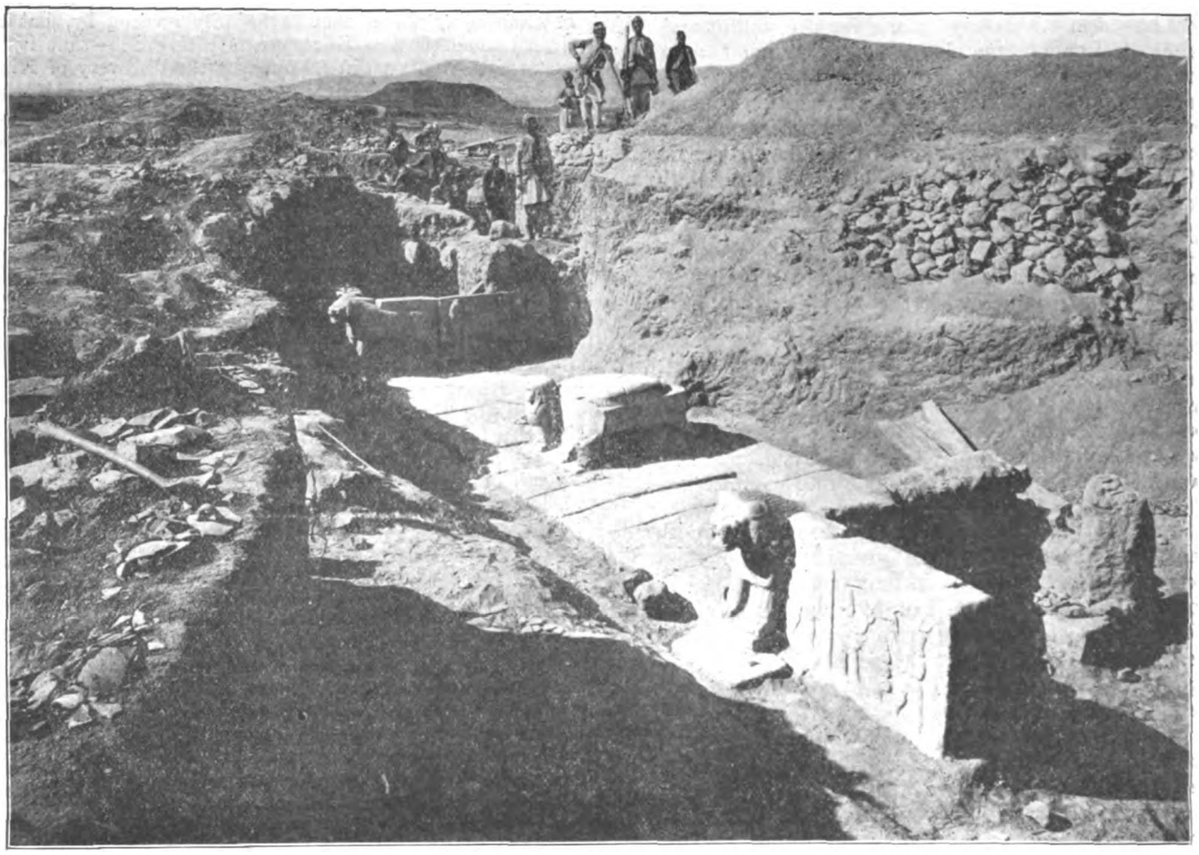
THE HITTITES.*

AT the outset of his first lecture Professor Garstang asked for that indulgence which he felt would be readily accorded to the treatment of a new science dealing with an unknown people using an unknown script and language. The subject, however, was not altogether new, so that a lengthy introduction was unnecessary; but inasmuch as it seemed to be ten years ago since the problem of the Hittites was last dealt with before the Royal Institution by Dr. Wright, the lecturer briefly reviewed the circumstances under which that problem arose, as a preparation for what was to follow.

There were four sources of evidence:—(1) The monuments and archives of the Pharaohs recounting their warfare with the Kheta and their allies in the North of Syria; (2) the references to the Hittites in the Old Testament, vague at all times, particularly in the Book of Genesis, but more readily intelligible after the settlement of the Israelites in Canaan; (3) the later records of Assyria, giving glimpses of the final overthrow of the Hatti; and (4) a series of prehistoric and unexplained monuments associated with peculiar hieroglyphic inscriptions in the North of Syria. It was in pondering upon these materials that Professor Sayce came to the natural conclusion that the unexplained monuments in question must be those of the Hittites, and finding the same hieroglyphs even in the west of Asia Minor, was led, in 1876, to his dramatic inference of a forgotten empire, an Oriental Power rivalling those of Egypt and Assyria. It was a brilliant hypothesis, imaginative and scholarly, smiled upon indulgently by the age of over-cautious and easier destructive criticism that is happily passing by, but confirmed none the less thirty years afterwards—that is, two years ago—in its main features by the discovery of Hittite archives at Boghaz Keui, in the north centre of Asia Minor, archives including diplomatic correspondence with the Courts of Babylon and of Thebes. The discoveries of Layard and Schliemann, Mariette and even of Champollion have not had effects more reaching than will these.

As Professor Sayce has published the results of his reasonings, and the main features of the problem are well known, the lecturer selected for illustration from this preliminary material only some few details of history and archæology of special interest in the course of his inquiry.

Historically, the first reference to the Kheta in the eighteenth dynasty is in the twenty-third year of Thothmes III., B.C. 1474, when they are referred to as the great Kheta, or Kheta the great, possibly as being chief among the Hittite peoples. They were then seated in the North of Syria; but looking back, there are earlier traces of the gathering and oncoming of the various tribes in the North of Syria, who later together formed the Hittite confederacy, under the leadership of the Kheta chieftain. (It is in this sense, by the way, that we use the word Hittite.) Thus in his twenty-third year the same king, addressing his army before Megiddo, says:—"That (vile) enemy of Kadesh has come and entered Megiddo, having associated with himself other chiefs of all the lands previously obedient to Egypt as far as Naharina."



The last-named country, seemingly somewhere on the plains between Aleppo or Aintabb and the Euphrates, is mentioned several times previously, even as far back as the reign of Thothmes, about B.C. 1550; for in the biography of Aahmes at El Kab there is an account of an expedition to repress a rising there, when the narrative says, "We found that enemy who had plotted conspiracy." So that the land had been conquered earlier, though no Egyptian record of the fact has come down to us.

Whoever "that enemy" may have been, the Hittite presence is felt, even upon the frontiers of Egypt, at a much earlier date—namely, in the twelfth dynasty. The reading Kheta on Stela C 1 in the Louvre has not been explained away, in spite of the wrigglings of philologists. And the strangers immigrant into Egypt depicted on the tomb walls at Beni Hassan are witness to the presence in southern Syria of a culture influence which has one peculiarity in common with that which typifies the Hittites—*e.g.*, the turning-up shoe and several features nearly related, as the embroideries and the lyre. This presence of an early branch, settled already in southern Syria, would explain many of the difficulties of the references in the Book of Genesis. This would fully accord with a fact of Babylonian history recently brought to light by Mr. King, that a Hittite invasion preceded the overthrow of the dynasty of Khammurabi. However that may be, from the time of Thothmes III. onwards the ever-renewed struggles of the Pharaohs with the Hittites are matter of common history. In the time of Amenhotep III., Egypt made an alliance with the Mitani (east of the Euphrates), who report in one of the Tell El Amarna letters a struggle with the Khatti. This struggle was destined to continue, but from one of the recently discovered tablets of Boghaz Keui it appears that it was not until 100 years later that the Mitani country was absorbed into the Hittite power. Further letters in the following reign, that of Khuenaten, indicate the leaguing together of the principalities of Syria with the Kheta, who from the north of Syria had gradually spread their influence south until, in 1375, they were finally established in Kadesh, in the northern Lebanon; indeed, a Kheta leader addresses thence a letter in a foreign language to Egypt about that time.

The monuments of Seti and Rameses the Great take up the story. The offensive and defensive alliance of about B.C. 1300 did not altogether end the struggle, for Rameses III. claims to have made a living chief of the Kheta captive; but the circumstances of these later wars are different. It is suggested, indeed, by the name of the mother of Psamtek III. in much later times, viz., Ti-ent-Kheta, that there may have been colonies of the Kheta in Egypt for several centuries. With regard to the treaty of peace, the lecturer referred to one of the seals, which is described as the image of Sutekh embracing the great chief of the Kheta. This recalls, as the late Italian scholar De Cara pointed out, one of the sculptures of Boghaz Keui. These sculptures he proposed to consider further in the light of recent discoveries, but the suggestion at the time was far-seeing and noteworthy. It is also remarkable that the other seal is described as representing the image of Sutekh embracing

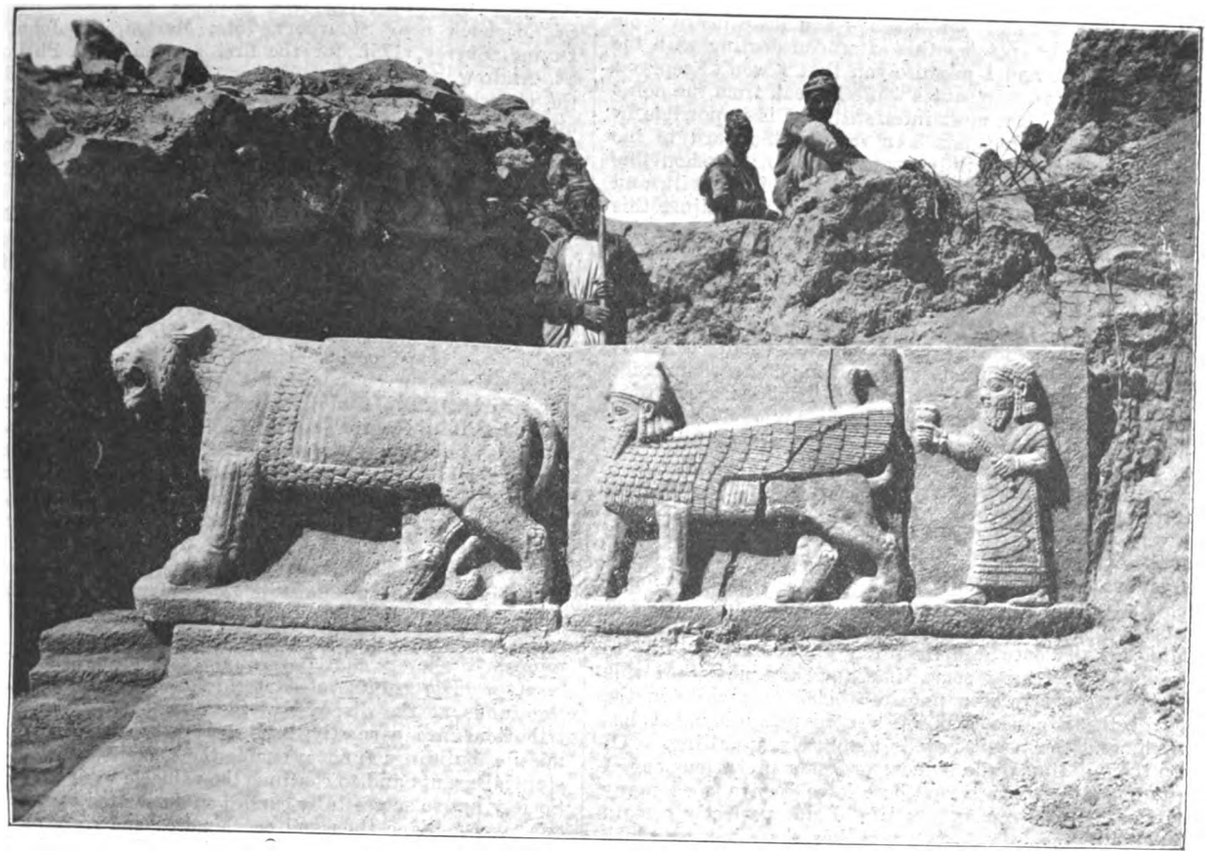
GENERAL VIEW.—BASE OF SCULPTURED PORTICO OF HITTITE PALACE AT SAKJE-GEUZI, DATE ABOUT 850 B.C.

the great Queen of the Kheta, who was priestess of the god. From other monuments of Rameses II. much is gleaned as to the racial types of the Hittite confederates, their arms and chariots and their fortresses. The frontier stronghold of Kadesh is several times represented, showing the extra mural towers which were used for purposes of defence, giving an enfilading fire against attack. This type was a definite stage more advanced than the Egyptian fortresses that are known, and it is interesting to compare these pictures with plans of Hittite fortresses to be considered later.

Other temple sculptures (or mural decorations) show the Hittite captives and warriors, in which many types may be made out, while several are conspicuous. These types were compared by the lecturer with the modern people of Hamath, Kyzyl Hissar, Eyuk, Kartal. Egyptian evidence of confederacy was confirmed by the Biblical references in the later books. Thus, "All the kings of the Hittites" (I. Kings). Earlier reference (Genesis) places Hittites in South of Palestine around Hebron; intermarriage was frequent; they were settled. "Thy father was an Amorite, thy mother a Hittite," of Jerusalem (Ezekiel xvi. 3, 45), is now full of a new ethnographical importance. This may well have been an earlier settling of Kheta or some branch of the Hittite people, coming by way of the mountain ranges fringing the seaboard of Syria, where the types mostly survive.

Assyrian monuments do not refer to the Hatti until 1100 B.C., but the Hittite archives make mention of Assyria 200 years earlier. At that time (Tiglath Pileser III.), the Hittites appear to be seated in strength on the Orontes, and Carchemish was one of their cities. Sargon (721-4 B.C.) finally overcame the Hatti.



Time did not allow the lecturer to develop the question of religious symbolism, which a comparison of the more striking sculptures with one another invites, especially viewed by the light of references direct and indirect in Strabo, Herodotus, and even Homer and Lucian; and in his second lecture Professor Garstang referred those interested in this point to the recent discussions of Ramsay (Luke, the Physician), Frazer (Adonis, Attis and Osiris), and Sayce (Transactions of the Society of Biblical Archæology), and passed on to a consideration of those recent discoveries that have placed the study of the Hittite problem upon a scientific basis. The connected ruins of Boghaz Keui, Jasily Kaya, Eyuk, Sinjerli and Sakje-Geuzi give a more coherent impression, and a description of their monuments will shortly be collected by Professor Garstang into an illustrated volume "The Land of the Hittites."

The lecturer proceeded to describe these settlements in order, commencing with Boghaz Keui and Jasily Kaya, which mark the site of the northern capital of the Hittite confederacy as opposed to other southern sites that were presumably also capitals, like Marash and Carchemish. We apprehend that Professor Garstang's view is that just as Athens and Sparta were capitals of constituent states of the Greek confederacy, so these northern and southern settlements were capitals of a Hittite confederacy.

The lecturer described the features of Boghaz Keui as comprising an acropolis with a series of buildings commencing with an early palace or temple of about B.C. 1300, having a courtyard and chambers, but no sculptures; then main fortifications erected probably between B.C. 1300 and 1200 of great blocks of stone without mortar. These were succeeded by a rebuilding of the palace between B.C. 1100 and 1000, a difference of its axial direction giving about 230 years interval from the earlier structure according to Sir Norman Lockyer's calculations. Between B.C. 900 and 800 sculptures of bold and decorative character were introduced in the flanking masonry of the gates with symbolical lions. Then about B.C. 570 the city fell during the invasion of the Lydian Crœsus.

Coming to Jasily Kaya, the lecturer described the relation of the great chamber and small gallery of this sanctuary in the rocks, with the arrangement of sculptures in the former representing two processions meeting and a central group of the divine triad, Khattu, Cybele and Attis, as to which the lecturer referred to the various theories advanced by Frazer, Ramsay and others. He pointed out that the minor deities, Asiatic and local, had been overlooked by scholars. New points made out by Professor Sayce are that the divinity of Kas follows Khattu, and that amongst the females represented the goddess of Comana appears. The costume of the priest-king and the absence of any other representation of the king pointed to the rule of a hieratical monarch, and agreed with the reference by Strabo to a priestly dynasty, in connection with which the lecturer discussed the theory of an eunuch priest. The little gallery Professor Garstang ascribed to the Holy of Holies, with its winged monsters guarding the entrance. The lion figure he described as the central cult object with its dagger emblem

DETAIL OF SCULPTURES.—HITTITE PALACE AT SAKJE-GEUZI.

and lions. The figures of Sutekh and Khetasar, the god and king embracing, was compared with the representation on the seal of the Hittite treaty with Rameses the Great, and in connection therewith the lecturer discussed Frazer's theory of the god leading and encouraging the king's representative to self-sacrifice. The facial types of the warriors on the sculptures were considered with regard to Ramsay's theory that these were Amazons simulating men, and Myres's theory that they were a beardless race mistaken for women by the ancients.

Eyuk said the lecturer was an example of a walled town and palace, such sites although rare in Asia Minor being plentiful in northern Syria. The sphinx gate here was the entrance to a palatial building, the facial type of the sphinx being analogous to that of the statue of Nefret, queen of Egypt in the twelfth dynasty. As at Jasily Kaya, so at Eyuk, there was exhibited a double eagle, as the probable emblem of Eyuk in both cases. A bull shrine and other cults were also indicated, in which probably the figures of musicians and a ladder scene bore a part. Reference was made by the lecturer to Macridy's recent excavations showing an earlier building, also with sculptures, including a wild boar hunt and stag hunt.

At Sinjerli as at Boghaz Keui, there was an earlier and a later building period, the former of which commenced about B.C. 1300, when the site of the future citadel was marked out by houses closely packed together, culminating about B.C. 1100, in the time of Tiglath Pileser I., in a city of 100 towers. From B.C. 900 to 745, the date of Tiglath Pileser III., the citadel rose in importance and experienced its period of splendour, when the palace was erected, adorned with sculptures, that formed the residence of the prince of Shamal. About B.C. 680 came the ruin of Sinjerli at the hands of Asarhaddon, the conqueror of Egypt, who numbered amongst his prisoners Pharaoh and the King of Tyre. Sinjerli was soon after rebuilt by a vassal of Asarhaddon.

Professor Garstang then described the interesting discoveries made by him last year at Sakje-Geuzi, particularly at the mound known as Jobba-Eyuk, the ruins of Kurdish and Roman buildings superposed over the Hittite stratum, and then the wonderful remains of the portico to a Hittite temple or palace, or possibly palace-temple. This portico consists of wing walls at either side, with a central structure. The wing walls have short returns at each end, and at the angles sculptured lions. On the walls themselves are figures of sphinxes, eagle-headed deities, the priest-king, the whisk-bearer, the royal falconer, and a scene showing two personages fertilising the sacred tree. The central structure has figures of sphinxes supporting a circular carved base, which may have been an altar or the pedestal of a statue, but more probably in Professor Garstang's opinion it was the base of a pillar helping to support the entrance. By the courtesy of Professor Garstang we illustrate some of the details of this portico, which it will be seen differ from, though generally resembling, Assyrian sculpture. In Professor Sayce's opinion these sculptures are the work of the Hittites of northern Syria, dating between the campaigns of Assur-nazir-pal in B.C. 880 and the conquests of Tiglath Pileser III. about 730 B.C. Continuing, the lecturer described the relation of these Hittite remains to the lower culture-strata in the mound, marked by distinctive character of painted pottery and overlying other strata of neolithic settlements.

In conclusion, Professor Garstang summarised what is at present known about the Hittites; that the fact recently established by Mr. King that Hatti invaded Babylonia during the Khammurabi dynasty about B.C. 2000 is confirmatory of the earliest traces of the people on the twelfth dynasty stela in the Louvre, the representation of them as immigrants at Beni Hassan, and the references in the book of Genesis, from which we infer that an early branch of the Hittites was already settled on the frontiers of Egypt in South Palestine. Then comes the first historical reference in the biography of Aahmes in the reign of Thothmes I. (B.C. 1550), and a definite mention of "great Kheta" in B.C. 1474. The Hittites repeatedly occur in Egyptian records till the time of Rameses III., after which the story is taken up by the Old Testament and Assyrian records. Later the Hatti appear about B.C. 1100 in the time of Tiglath Pileser I. and Sargon finally overcame them, B.C. 721. The land they occupied was the Taurus region, with extensions to northern Syria and the plateau of Asia Minor. The race was very mixed and they seem to have mingled freely with pre-existing local tribes, which may account for the clear Mongolian and Semitic elements. They were organised as a confederacy of the states under the Kheta chieftain, who appears to have come from the Taurus region, and whose capital in B.C. 1300 was at Boghaz Keui.

THE BUDGET AND THE BUILDING TRADE.*

MY Lord, Ladies and Gentlemen,—You have heard some very brilliant speeches this afternoon dealing with the Budget generally, and I promise you that I won't keep you more than two or three minutes while I speak from the point of view in which I am most interested. It is impossible in my case, after all that has been said with regard to the unemployment in the building trade, not to talk shop this afternoon. I want you to remember if you kindly will, and bear it in mind wherever you go in agitating against this Budget, that the building trade is by far the largest individual trade that exists in this country. You see that it obtains everywhere. Of course the workers in the building trade are in a large minority in the cotton districts, coal districts, mining districts, or in special towns, but as every town, small or large, has its one, two, three, twenty or thirty builders, the aggregate number of working-men in our trade is by far greater than in any other. That being so, it is obvious that anything that promotes unemployment, and it is that which I am entirely going to speak about this afternoon, affects very seriously the building trade.

Now, the effects of the threats of Mr. Lloyd George, the Chancellor of the Exchequer, on more than a few trades were very serious, and they at once had an enormous effect upon the building trade. People were alarmed, and I could give you no end of instances, not only of work abandoned which had practically been started, but I could give you instances without end of people who were contemplating building, who at once said that they would have nothing to do with it. That was some time ago, and now that this Budget has actually been put into black and white in the shape of the Finance Bill, still more unemployment has occurred, and the result now is absolutely appalling. Of course the building trade is more or less a precarious one, I admit, and at certain times there have been a good many unemployed, but never in my life, I am perfectly certain that never in the last thirty years, has there been so much unemployment of good men. Splendid bricklayers, splendid joiners, men that I should be only too glad to employ, I might say friends of mine, are walking the streets in order to find a job. This is a most serious matter. We all know that there must be a certain margin of unemployment, and that the weak and idle men drift away and cause chronic unemployment, but at this moment there are splendid, industrious, honest men unemployed in huge numbers, and how they stand it is really wonderful. I believe that they are beginning to see the cause, and what I want to impress upon every gentleman in this room is as he goes about the country in season and out of season, to try and convince the working man, and never stop pointing out to him, this particular effect upon his prospects caused by the Budget.

I believe that if the Government had come into power with a mandate—you know a mandate is a modern word, but a very popular one—to so frame their measures as to produce unemployment they could scarcely have done more than to propose this Budget. Of course, we builders we shall suffer individually no doubt, and all of you will suffer, but you are able to bear a certain amount of suffering and still have the wherewithal to live, but these men have not, and their suffering means want of bread and want of means. It is indeed a strange irony that this Government, who were always talking about improving the social conditions of the workers, should at once proceed to do their best to ruin them.

In view of the speakers who are to follow, and the interesting information you will get from them and the late hour of the evening, I will simply say again that I hope you will keep pegging away day and night, to try and do your best to upset this Budget by all means in your power.

* Report of speech by Mr. John Howard Colls, Past President of the Institute of Builders and of the Master Builders' Association, delivered at the Queen's Hall, Langham Place, W., on July 13.

INCORPORATED SOCIETY FOR PROMOTING THE ENLARGEMENT, BUILDING AND REPAIRING OF CHURCHES AND CHAPELS.

THIS Society held its usual monthly meeting on Thursday, July 15, at the Society's House, 7 Dean's Yard, Westminster Abbey, S.W., the Rev. Canon C. F. Norman in the chair. There were also present the Rev. H. B. Coward, the Rev. C. F. Nolloth, the Hon. E. P. Thesiger, C.B., Messrs. George Cowell, E. Lee-Warner, J. C. Powell, F. H. Rivington, Lewis Wigram and Joseph Monday (Secretary).

Grants of money were made in aid of the following objects, viz.:—Building new churches at Lower Mitton, St. Michael, near Stourport, 75*l.*; Merton, St. John the Divine, Surrey, 125*l.* for the first portion; and Purlwell, St. Andrew, near Batley, Yorks, 125*l.*; towards rebuilding the church at Haslington, St. Matthew, near Crewe, 50*l.*; and towards enlarging or otherwise improving the accommodation in the churches at Boyne Hill, All Saints', near Maidenhead, 75*l.*; Cann, St. Rumbold, Dorset, 15*l.*; Fincham, St. Martin, Norfolk, 20*l.*; Hedworth, St. Nicholas, Durham, 35*l.*; Ipswich, St. Bartholomew, 20*l.*; Llanddewi, St. David, Denbigh, 10*l.*; Sefton, St. Helen, near Liverpool, 40*l.*; Skenfrith, St. Bridget, near Monmouth, 25*l.*; Trent Vale, St. John the Evangelist, Staffs., 50*l.*; Warmley, St. Barnabas, near Bristol, 20*l.*; and Whatcote, St. Peter, Warwickshire, 15*l.* Grants were also made from the Special Mission Buildings Fund towards building mission churches at Caergeiliog, near Holyhead, 15*l.*; Nedging Tye, Suffolk, 5*l.*; Scackleton, near York, 20*l.*; and Washford, near Taunton, 30*l.* The following grants were also paid for works completed:—Hill, St. James, near Sutton Coldfield, 75*l.*; Shuttington, St. Matthew, near Tamworth, 25*l.*; Eastney, St. Margaret, Hants, 200*l.*, on account of a grant of 1,000*l.*; Sunnyside, St. Michael, near Berkhamsted, 120*l.*; West Kirby, St. Andrew, Cheshire, 155*l.*; Epsom, St. Barnabas, Surrey, 120*l.*; Southover, Wells, Som., 25*l.*; Charterhouse-on-Mendip, Som., 20*l.*; Ebbw Vale, Mon., 10*l.*; and Methwold, Norfolk, 15*l.* In addition to this the sum of 206*l.* was paid towards the repairs of eleven churches from trust funds held by the Society. The grants voted at this meeting have exhausted the funds at the disposal of the committee. Liberal contributions are earnestly invited both to the general and mission buildings fund to enable the committee to vote substantial grants and to continue the valuable work which this Society has so successfully carried on during the past ninety-one years. Nine thousand one hundred and sixty places—*i.e.*, more than half the parishes in England and Wales—have been aided by the Society with grants from the general fund amounting to 1,062,765*l.*, and 973 grants have been made from the mission buildings fund amounting to 26,229*l.*

KEBLE COLLEGE, OXFORD.*

By D. J. MEDLEY, M.A.

(*Concluded from page* 23.)

VERY shortly after the presentation of the report of this committee JOHN KEBLE died (March 29, 1866), and those who were anxious to perpetuate his memory realised the peculiar fitness of associating the newly proposed College in Oxford with his name. One important modification took place in the scheme as proposed by Dr. SHIRLEY's committee. The College was not to be confined to "persons desirous of admission into the Christian ministry," but to be open to all members of the Church of England, whether preparing for ordination or not. A committee for raising a fund was formed, with Archbishop LONGLEY at its head. Rather more than 50,000*l.* was subscribed directly. A site of about four and a half acres was purchased from St. John's College. Mr. WILLIAM BUTTERFIELD was chosen as the architect, and on the anniversary of Mr. KEBLE's birth, April 25, 1868 (St. Mark's Day, as every Keble man knows) the foundation-stone was laid by Archbishop LONGLEY. A further step was taken when, largely through the instrumentality of Earl BEAUCHAMP, a staunch friend of the College to the end of his life, a Royal Charter of Incorporation was obtained, and Archbishop LONGLEY's successor, TAIT, accepted for himself and succeeding Archbishops the post of Visitor of the College. Opportunity was taken of the Commemoration of 1870 to open the College with ceremonies presided over by the Chancellor, the Marquis of SALISBURY, and in the following October undergraduates were admitted into residence. Finally, in April 1871, by degree of Convocation, the College was admitted to the privileges of the University. Great opposition was aroused by these various proceedings, and the legality of this last act was acrimoniously challenged.

* See Illustrations.

Digitized by Google

The reason of the hostility was chiefly twofold—entrance to the College was to be restricted to members of the Church of England; and so apprehensive were the founders of the power of the secularising spirit, that there was reserved to the governing body the right, if they thought fit, of removing the College away from Oxford altogether. The government of the College was also a novelty. The charter had been granted to a Council representing the original subscribers, who elected the Warden of the College, who was also their president, and filled up vacancies in their own body by co-optation. This Council, consisting almost entirely of distinguished Churchmen, both clerical and lay, not necessarily residing in Oxford, has the entire management of the finances. Three Wardens have presided over the destinies of the College. The present Bishop of SOUTHWARK, whose nineteen years of rule fixed firmly the lines on which the new College has run to such unexpected success; the Rev. R. J. WILSON, Fellow of Merton and Warden of Radley; and the present holder of the office, the Rev. W. LOCK, since 1895 also Dean Ireland Professor of Exegesis, who has devoted his life to the destinies of the College, and is well known to the general public as the biographer of KEBLE and editor of the *Christian Year* and the *Lyra Innocentium*.

The buildings of the College have been gradually erected. With the first large sum at their disposal the committee of the Memorial Fund not only bought the site, which cost 7,000*l*., but also erected two blocks which form the east and west sides of the main quadrangle, with rooms for a hundred undergraduates and six tutors. In contrast to the stonework of the older Colleges the new College was built of variegated red and yellow brick with Bath stone dressings. A massive gateway on the east side opposite the University Park forms the entrance to two quadrangles flanking it on the north and south. Both quadrangles have been gradually all but surrounded by buildings. At first the hall and chapel were temporary structures, the friends of the College hoping that further gifts might enable them some day to erect public buildings worthy of the great College they had planned. Their hopes were fulfilled in a most unexpected manner. In the summer of 1872 Mr. WILLIAM GIBBS, of Tyntesfield, Somerset, who had given munificently and most unostentatiously to many objects connected with the Church of England, at the suggestion of Sir J. T. COLERIDGE offered the gift of a College chapel. The foundation-stone was laid by Mr. GIBBS himself on St. Mark's Day, 1873. In 1875 Mr. GIBBS died, and shortly after there came through Mr. HENRY HUCKS GIBBS (afterwards Lord ALDENHAM), a member of the Council of the College, the offer of a companion building to the chapel, which should fill in the south side of the great quadrangle and should contain both hall and library. It subsequently transpired that the donors were the two sons of Mr. WILLIAM GIBBS, who desired thus to honour their father's memory by completing his work. Again on St. Mark's Day, 1876, a great company assembled, and the same day witnessed the opening of the chapel by the Visitor of the College and the laying of the foundation-stone of the hall and library by the Chancellor of the University.

The College buildings now consist of two quadrangles. Of these the larger, lying to the right of the gateway, is second in size only to Tom Quad at Christ Church. A broad gravelled terrace runs round a sunk grass plot, across which run narrower gravelled paths. East and west lie two large blocks of undergraduates' and tutors' rooms. On the north stand the chapel and a small block of rooms. The southern side is occupied by a building which contains the hall and library above, lying respectively right and left of the staircase, while the space below is divided up into a senior and junior common-room, a lecture-room, and good kitchen offices. Behind the western block of living rooms there is a garden which is the only free space remaining to the College.

The smaller quadrangle lies to the left of the main gateway. The east side is occupied by a large block of rooms, terminating, after a short interval, in the Warden's lodgings. On the west side are a smaller block of living rooms and offices for the servants, many of whom live in the College. Thus room is found in the buildings for 155 undergraduates, and at first no one *in statu pupillari* was allowed to live outside. But the pressure on space was considerable, and ultimately the rule of residence within walls was so far relaxed that senior men were able within limits to obtain leave to spend their last year in lodgings. This increased the numbers of the College, which is now the third largest in the University.

So far as the buildings go interest centres naturally in the chapel, the hall, and the library. The chapel is approached through a western door by a short cloister, which connects it to the small northern block of living rooms, and also gives an exit into the quadrangle. It towers above the block to which it is attached, and is flanked on either side by large buttresses ending in a stone cornice and parapet surmounted by a stone pinnacle. The wall is divided horizontally into three spaces, the lower one arcaded in stone, the second relieved by surface pattern work, while the uppermost is pierced by spacious and lofty windows. The height of the outside wall is 90 feet to the ridge of the roof, while the window sills are raised 40 feet from the ground for purposes of internal decoration. On the south, the quadrangle, side the face of the huge mass is broken by a wide south transept and by a handsome entrance porch in the westernmost bay, which is carried up the full height of the building. Within the arch of the porch stands the *Agnus Dei;* above it, treated as a finial and also carved in stone, is a pelican feeding its young, a symbol of the sacramental union of CHRIST with His people, while the full gable is finished by a colossal figure, nine feet high, of St. MICHAEL, with the dragon at his feet. Each of the buttresses contains a niche filled with a statue, those at the western end representing Old Testament and those at the eastern end New Testament saints. Below these at the eastern end are two larger niches with statues representing the Angel GABRIEL and the VIRGIN MARY in the scene of the Annunciation, while in smaller niches above them stand figures of the Apostles St. PETER and St. PAUL. Internally the length of the chapel is 124 feet by 35 feet in width. It is divided into six bays, the first three forming the nave, the fourth the choir and transepts, and the remaining two the sanctuary. The nave is filled with oak seats arranged to face eastwards and not running along the north and south sides. This latter, which is the usual form of seating in a College chapel, dates from a period when those who attended such a chapel were on the Foundation as life members of it. Few such members remain at any College, and none such were contemplated in the new arrangements. It therefore seemed suitable that the seating in the chapel should follow the plan observed in ordinary parish churches. In the choir bay, however, the seats run along the north and south sides, and on the south side there is a large transept originally built as an organ chamber. Subsequently the organ was raised, and below it the transept has been cleverly turned into a small side-chapel, where is hung one of the treasures of the College, Mr. HOLMAN HUNT'S picture *The Light of the World*. This was the gift of Mrs. COMBE, widow of Mr. T. COMBE, of the Clarendon Press, an early friend and patron of some of the chief members of what is known as the pre-Raphaelite school of English artists. The decoration of the walls is elaborate and on a carefully thought out scheme. The lowest of the three horizontal spaces already mentioned is occupied by a stone arcading. In the second tier are ranged subjects and figures in mosaic framed in stone panels, and the third tier carries the windows filled with painted glass in what modern taste is inclined to criticise as crude and striking colours. The glass and the mosaics taken together are an attempt to illustrate within the available space, and "in some sort after the manner of the *Christian Year*," the dealings of GOD with the Church in patriarchal, Jewish, and Christian times successively. By juxtaposition of type and antitype the relationship is brought out between the Old and the New Testament. The subjects of the panels are sufficiently obvious to any

Digitized by Google

spectator, the western half of the chapel being occupied with subjects from the Old Testament, the easternmost with subjects from the New Testament. At the east end, to which the whole scheme leads up, the window contains the scene of the Ascension, while below is placed a mosaic quatrefoil representing Our LORD as depicted by St. JOHN in the Revelation, with the seven candlesticks around Him and the seven stars in His right hand. Below again stands the reredos of various stones and marbles, in the centre a large Latin cross of white marble, on either side in mosaic the four living creatures of the Apocalypse. The whole reredos is surmounted by four angelic figures carrying musical instruments.

The hall and library do not, of course, need so much description. The hall is about the same length and breadth as the chapel, and is therefore one of the largest in Oxford. It is panelled all round, the windows are traceried and filled in with glass bearing simple patterns, and on the north side is a projecting gallery. The most interesting features of most College halls are the portraits, and although the youth of Keble has caused her to produce few sons whose deeds yet deserve the perpetuation of their memories within her walls, the College rightly attempts to prevent future generations from forgetting the early founders and benefactors whose names are woven into the story of her origin and beginnings. The place of honour in the middle of the dais is given to a posthumous portrait of Mr. JOHN KEBLE, by GEORGE RICHMOND, a beautiful piece of painting. One of the most interesting to the majority of visitors will be the portrait, also by GEORGE RICHMOND, of Dr. LIDDON at about the age of forty. He was a member of the Council of the College, and took a warm interest in its fortunes. Most Keble men would regret that the first Warden to whom the College owes so much, and to whom many individual men owe more, should be perpetuated to future generations by the singularly unattractive portrait on the walls. The same might be said of the portrait of Dr. PUSEY, whose personal influence and munificence contributed perhaps more than that of any one other person to the foundation and first starting of the College. Some of the pictures, such as those of Archbishop LONGLEY and Canon SHIRLEY, represent active well-wishers of the College who did not live to see its opening. Earl BEAUCHAMP's powerful and ungrudging service gains an appropriate recognition. Mr. J. A. SHAW STEWART was Treasurer of the Memorial Fund and for a while Bursar of the College. Dr. ROBERT WILSON, Dr. LOCK, Mr. AUBREY MOORE, and Mr. WAKEMAN are names honoured by a much wider circle than that of Keble graduates. Mr. WILLIAM GIBBS's princely gift assures to his portrait an honoured place.

Opposite to the hall stands the library, also a fine room. In it is placed an interesting bust of Cardinal NEWMAN, by WOOLNER, the gift of Mrs. COMBE. There are also busts of KEBLE and PUSEY by GEORGE RICHMOND. The books from the library of Mr. KEBLE were enclosed within gates in the first left-hand bay in order to check the depredations of the autograph-hunter! In a glass case within the bay there are to be seen many manuscripts of Mr. KEBLE, including one of a large portion of the *Christian Year* and another of the *Lyra Innocentium*. Another interesting feature of the library is the bequest of Canon LIDDON, which is especially rich, among other things, in Dante literature.

So young a College cannot be expected to have great wealth of historical memorials; but in days to come the historian of the English Church in the nineteenth century will scarcely be able to pass by the valuable collection of materials which is being gradually accumulated by generous bequests within its walls.

Two Two-light Memorial Windows have recently been erected in the north aisle of Mamble Church, Worcester, the subjects being our Lord and the Baptist and the Good Shepherd and David singing the "Shepherd" Psalm. The windows were designed and executed by Mr. H. Gibbons Murray, of Britannia Studio, Caroline Street, London, S.W.

INTERIOR OF CHURCH OF ST. AGNES, LIVERPOOL.

THIS church was one of the buildings that contributed to the high reputation of the late Mr. J. L. PEARSON, R.A., and was erected by Mr. H. DOUGLAS HORSFALL, of Liverpool, in memory of his father. The church was commenced in 1883, and was consecrated in January, 1885. The illustration here given is from an etching by Mr. W. V. COLLETT, an artist whose work has brought him of late years into some prominence. The interior of the church, unlike the exterior, is remarkable for its dignified richness of effect, and every detail bears the impress of a refined mind. Mr. COLLETT in his etching has most successfully brought out that religious atmosphere that seems to have been the architect's chief aim, and especially the subtle light effects. The seven sanctuary lamps suspended from the ceiling recall the churches of Italy. In the process of photo-lithography some of the beauty of the etching has unfortunately been lost, but our illustration clearly indicates the skill which Mr. COLLETT has brought to his work. The dimensions of the picture are 18 inches by 13 inches. The edition is limited to 325 proofs; of these 25 Remarque proofs, signed and numbered, are obtainable at 5*l.* 5*s.*, and 300 signed artist's proofs at 2*l.* 2*s.* each. They may be had from Mr. W. P. WETHERED, Mossley Hill, Liverpool, or from the artist himself, at Downs Park West, Bristol. Any profit derived from the sale is to be devoted to the church.

OXFORD COLLEGE SERIES, KEBLE.—INTERIOR OF CHAPEL.

THESE views of Keble College are in illustration of the article thereon, by Professor MEDLEY, completed this week.

PELHAM SCHOOL, WIMBLEDON.—PLANS—THE BOYS' ASSEMBLY HALL—CORRIDOR, GIRLS' SCHOOL—CLASS-ROOM, INFANTS' SCHOOL—HEAD-MISTRESS'S ROOM, GIRLS' SCHOOL—A COMMUNICATION DOOR—CLOAK-ROOM, BOYS' SCHOOL.

THESE schools were opened on the 14th inst. by the Right Hon. Lord ALVERSTONE, Lord Chief Justice of England. In our last issue illustrations were given of the north-east view, an entrance doorway and an entrance gateway. As was then stated, accommodation is provided for 1,000 pupils, the infants being on the ground floor, the girls on the first floor, and the boys on the second. It will be seen from the plans that the floors are similar in general arrangement. The assembly halls have panelling of wood, stained green up to 7 feet. Antique glazed tiles are used for dadoes in class-rooms and corridors. The architect is Mr. H. P. BURKE DOWNING, F.R.I.B.A., whose designs were selected after a limited competition.

Mr. Nathan Solomon Joseph, F.R.I.B.A., of Porchester Terrace, Hyde Park, W., the oldest member of the committee of the Jewish Board of Guardians and brother-in-law of the Chief Rabbi, who died on June 11, aged 74, left estate of the gross value of 52,848*l.* 13*s.* 11*d.* The testator amongst many other bequests left 25*l.* to the Architects' Benevolent Institution.

Official Statistics have been published regarding mines and quarries of the United Kingdom in 1908. At the quarries under the Quarries Act there were 85,475 persons employed, of whom 54,449 worked inside the actual pits or excavations, and 31,026 outside. Compared with 1907 there is a decrease of 1,445 among the inside workers and of 894 among the outside workers, making a total decrease of 2,339 in the number of persons employed at quarries. The total quantity of stone and other minerals obtained from the quarries was 44,732,016 tons, of which 4,801,561 tons were iron ore. Adding to the produce of mines and of quarries over 20 feet deep 789,181 tons obtained from shallow open workings, there was a total output of iron ore of 15,031,025 tons. At the quarries under the Quarries Act there were ninety fatal accidents, which resulted in ninety-two deaths. Compared with 1907, there is an increase of two in the number of accidents, and of three in the number of deaths.

SECOND CHURCH OF CHRIST, SCIENTIST, LOS ANGELES.

SECOND CHURCH OF CHRIST, SCIENTIST, LOS ANGELES, CALIFORNIA.

THE Second Church of Christ, Scientist, now nearing completion on West Adams Street, Los Angeles, California, represents an expenditure of a trifle in excess of $300,000, and is one of the most important and at the same time the most costly Christian Science church west of New York city.

The structure occupies a ground area of about 100 by 150 feet, and is centrally located on a plot of ground fronting 200 feet on West Adams Street, by a depth of 250 feet, thus affording ample opportunity for landscape effects. The design is Italian Renaissance in modified form, the Corinthian order having been adopted for the entrance portico. In plan, the main auditorium, having a seating capacity of 1,200, without galleries or obstructions of any kind, is in the form of a Maltese cross. Its dimensions are 93 by 106 feet, surmounted by a dome 70 feet in diameter, the crown of which is 96 feet above the floor.

The treatment of the walls and vaulted ceilings, as well as the dome proper, is strictly architectural and is executed consistently in all of its minutest details. The high panelled wainscotting, the doors and pew seating, and all other wood work is of selected mahogany stained a soft brownish tone, while the floor will be completely covered with interlocking rubber tile of harmoniously contrasting colours.

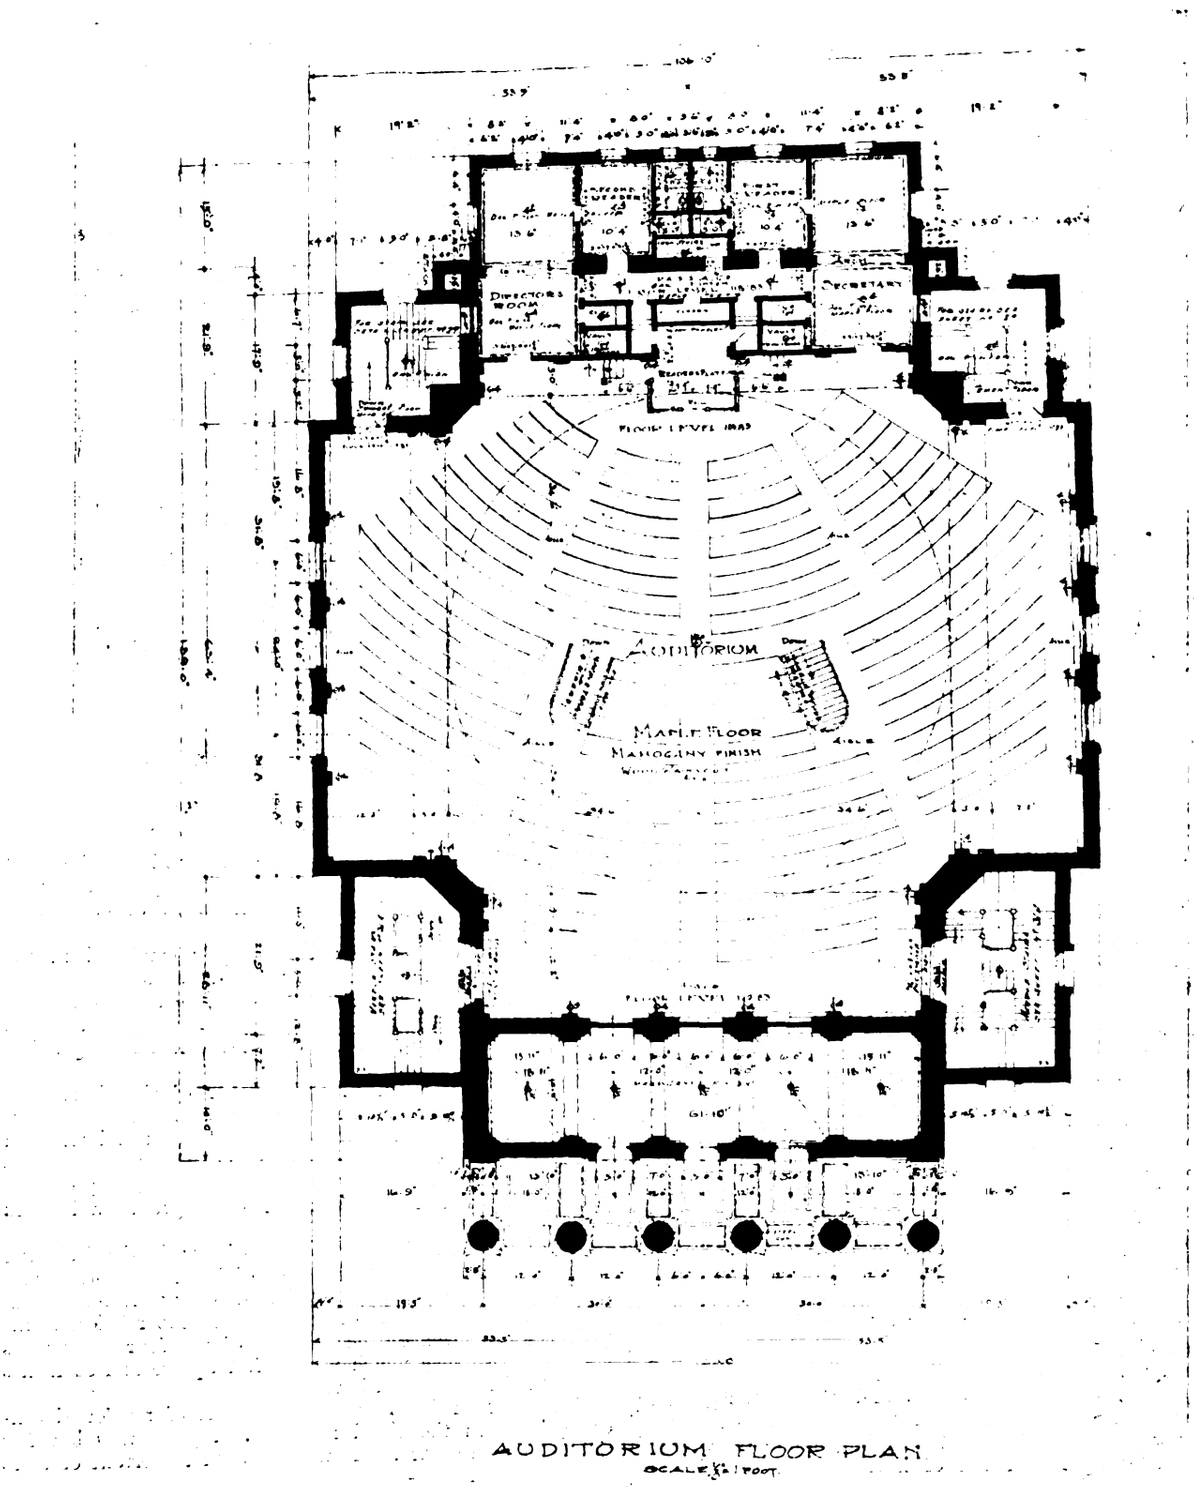
The terraced approaches to the portico are spacious and have an air of quiet elegance and dignity. The entrance vestibule is generous in proportions, 3 feet in height and terminating in a groined arched ceiling. This vestibule communicates directly with the foyer, 32 by 65 feet in size, of clear, unobstructed space with tiled floor, marble wainscotting, beamed and panelled ceiling and large twin marble fireplaces at either end. To the right and left of the foyer are located the main stairways leading to the auditorium, while twin tunnel stairways lead directly ahead and land in the centre of the auditorium. In addition to these, two commodious rear stairways are provided and are reached from the side or Sunday-school entrances. In the rear of the foyer is the Sunday-school with a seating capacity, in cases of emergency, such as overflows, &c., of over 800 and with special arrangements for children's classes.

Cloak and toilet rooms, also literature and ladies' retiring rooms are contiguous to the foyer. In the rear of the auditorium are provided the readers' rooms with adjoining private toilets; the secretary's and directors' rooms with all necessary conveniences, and an ample loft to house the great organ. A complete modern and thoroughly equipped heating and ventilating plant is about to be installed, also a vacuum dust-cleaning apparatus.

Reinforced concrete has been largely employed in the construction of this church, making it substantially fireproof. The dome is a noteworthy feature and is said to be the largest concrete dome, not only in the United States, but in the entire world, nothing of the like having before been attempted.

The materials used in the exterior of the church are light grey granite for the lower part, while the walls are faced with a matt or dull-glazed white brick and trimmed with terra-cotta of the same colour and texture. The dome and lantern surmounting it are covered with heavy copper, and the gabled roofs with an olive green dull-glazed shingle tile.

The building rests on a stratum of gravel. In designing the foundations a bearing power of 3,000 lbs. per square foot was assumed, and the dead loads only were considered.



The foundations are of concrete without reinforcement, with the exception of the footings of the four great piers carrying the dome, which was 18 feet square and 30 inches thick reinforced twisted bars.

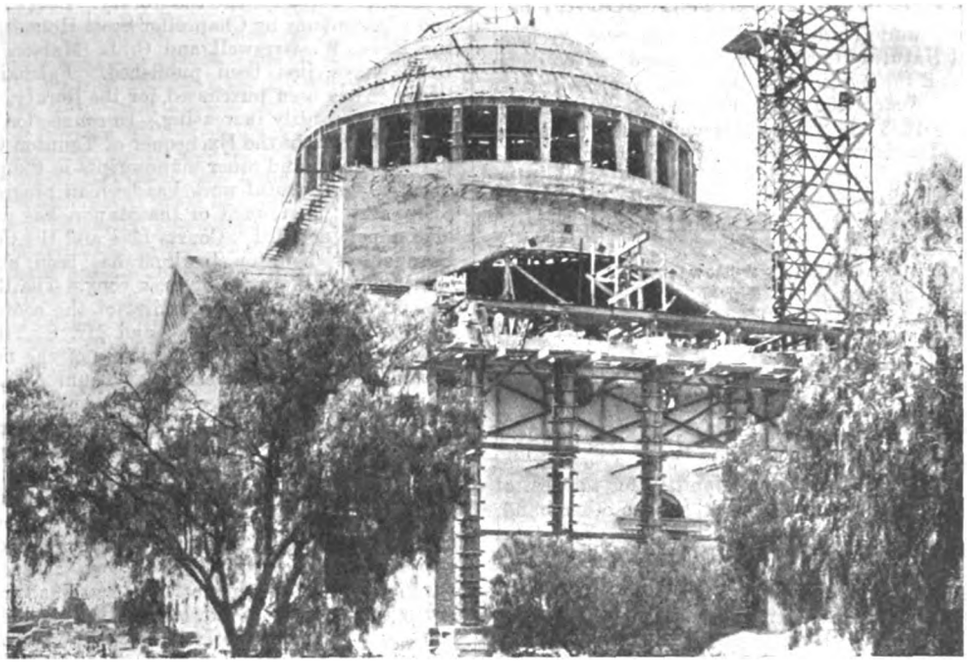
The floors, roofs, stairways, &c., are of reinforced concrete, built in the usual manner and presenting but few points of particular interest. The most important of these are the following:—

The floor over the foyer is carried on beams, spaced 12 feet on centres, having a clear span of 35 feet, but, owing to the pitch of the floor of the auditorium, these beams are but 26 inches deep at one end. The columns carrying the floors are generally 14 inches square reinforced with four ¾ inch twisted bars, wrapped spirally with No. 6 gauge wire, spaced 2½ inches on centres. The maximum load on these columns is 500 lbs. per square inch on the area enclosed by the reinforcement.

The four piers carrying the dome and its supports, consisting of a dead load of 1,400 tons, have each an area of 10 square feet, and are reinforced by a steel column made of four 3-inch by 3-inch by ⅜-inch angles spaced 28 inches from back to back, double latticed with 2½ inches by ¼-inch bars, and additional reinforcements of three 3-inch by 3-inch by ⅜-inch tees in the outside corner. The four concrete girders connecting these columns have a clear span of 68 feet, and are 20 feet deep at the supports, 10 feet deep at the centre, finishing 16 inches thick. These girders are reinforced by hollow steel trusses and twisted bars as shown in the accompanying detail. These steel trusses were designed

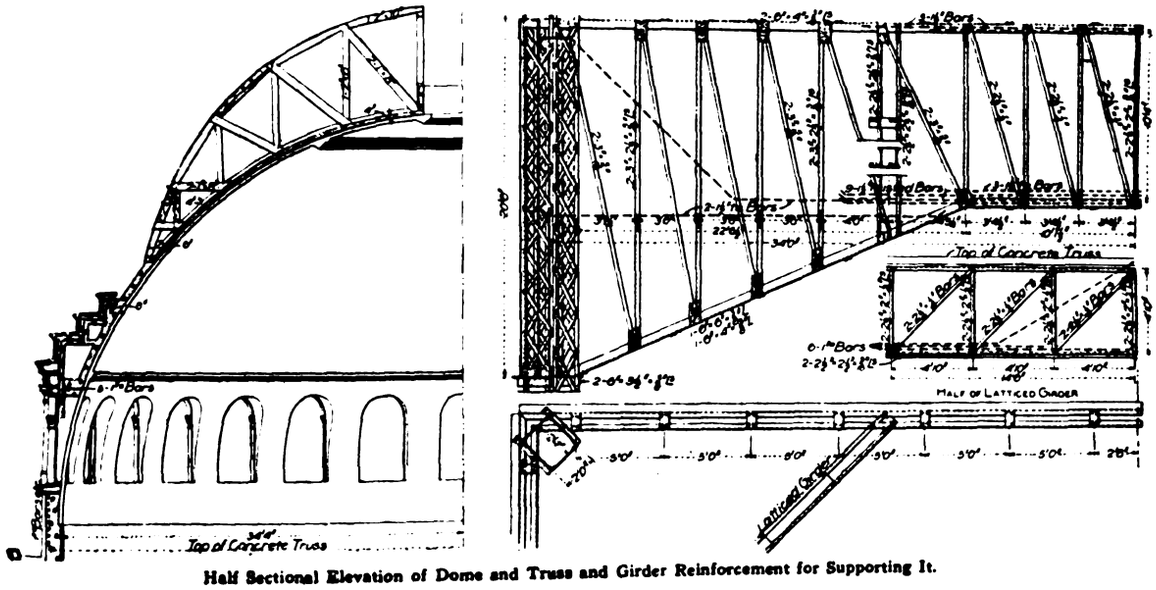
Digitized by Google

PLAN, SECOND CHURCH OF CHRIST, SCIENTIST, LOS ANGELES.



and built to carry the weight of the forms and wet concrete and to take some of the tensile, compressive and secondary stresses due to the loads of the completed structure. Additional steel was used both in the upper and lower parts of the girder, as shown, to take the remaining stresses.

In constructing this work the steel columns were assembled in their full length and hoisted to and guyed in their final positions. Short cross arms were secured to the tops and the steel trusses hoisted by block and tackle and hung from these arms. After the four trusses were secured in their correct position, four hollow latticed girders 30 feet long and 5 feet deep were bolted to them across the corners, at an angle of 45 degrees. The centres of the trusses and the girders are points of support for the dome. Eight additional points of support are located at the centres of eight intermediate concrete beams on lines tangent to the dome and are supported at their ends by the trusses and girders.



The concrete for the piers, girders, dome and roofs was hoisted in a concrete bucket to a point about 30 feet above its final resting place and then dumped into a 7 inch sheet iron pipe, which conducted it to its forms. This pipe had a swivel joint at the centre of the building, which facilitated the delivery of the concrete uniformly in the forms on all sides of the building.

Three ¾-inch bolts were imbedded in the concrete of the trusses and the girders directly below the centres of each of the columns of the dome, and 4-inch by 4-inch blocks were afterward secured by these bolts and formed the supports for the outer ends of 32 radial trusses, which supported the forms for the dome. The other ends of these trusses were

Digitized by Google

SECOND CHURCH OF CHRIST, SCIENTIST, LOS ANGELES.
CENTERING AND FORMS IN POSITION FOR CONCRETE.

Half Sectional Elevation of Dome and Truss and Girder Reinforcement for Supporting It.

SECOND CHURCH OF CHRIST, SCIENTIST, LOS ANGELES.

carried on a 16-foot square wooden tower erected on the floor of the auditorium. The rough boarding of the form of the dome was made up in sections and hoisted into position. The first section of the dome consists of a 3-foot ring 16 inches thick, bearing on the beams, girders, and trusses, and reinforced at the bottom with two 1-inch bars and on the outer face with six 1-inch bars. The next section of the dome, as constructed, consisted of the 32 columns and a horizontal circular ring connecting the tops of these columns. The columns have a minimum section of 12 inch by 14 inch, and are reinforced with four ¾-inch twisted bars wrapped spirally with No. 6 wire, spaced 2½ inches on centres, the ends of the bars projecting 6 inches or 8 inches into the lower and upper rings. The upper ring is 16 inches deep and about 28 inches wide, and is reinforced with five 1-inch twisted bars on its outward face. The shell of the remainder of the dome rests on this upper ring or girder and is 8 inches thick at the base and 4 inches thick at the crown, the horizontal reinforcement consisting of ½-inch twisted bars spaced 6 inches and 12 inches on centres, while the same bars were spaced 18 inches on centres in the opposite direction. The forms of the dome were removed 90 days after the concrete was placed and after all the terra cotta had been set in position. The deflection of the trusses was between ¼-inch and ⅜-inch, while the deflection of the dome was only $\frac{1}{16}$ of an inch.

Galvanised iron wires were imbedded in the concrete for anchoring the brick and terra cotta facing, and, as all this work was grouted with concrete, a very strong bond was secured.

Mr. A. F. Rosenheim was the architect of this building and Mr. A. C. Martin was the structural engineer. The C. J. Kubach Company was the contractor.

Mr. David Davies, M.P., has intimated his intention to provide at the joint cost of himself, his mother and his sisters a new college hall and men's hostel for the University College of Wales at Aberystwyth. The cost is estimated at 8,000*l.* The idea is to provide a college hall, with subsidiary accommodation, capable of enabling fifty professors and 300 students to dine together, and ultimately to afford full residential accommodation for all students of the college, both ordinary and "normal." Mr. Davies hopes that this plan will strengthen the sense of corporate life in the college, and also assist in bringing the teaching profession within the sphere of university education in Wales, instead of restricting their education within detached training colleges, and so cutting them off from the main current of higher education in Wales.

SOMERSET ARCHÆOLOGICAL SOCIETY.

THE sixty-first annual meeting of the Somerset Archæological and Natural History Society opened at Wells on the 12th inst., and the proceedings extended over the greater part of the week. Nearly 200 members of the Society participated. It was in 1888 the Society last visited the cathedral city. The annual meeting was held in the Guildhall on the 12th inst., under the chairmanship of Mr. A. F. Somerville, High Sheriff. The Bishop of Bath and Wells was elected president for the ensuing year. The annual report contained the following:—

Since the last report sixty-four new names have been added to the list of members. The losses by death and resignation have been thirty-five; altogether the net gain has been twenty-nine. The total membership at date is 795 against 767 at the time of the annual meeting last year. The balance of the account at the end of 1907 (the general account and the Castle Restoration Account of former years having now been combined) was 168*l.* 18*s.* against the Society. At the close of 1908 there was a deficit of 216*l.* 9*s.* 8*d.* In neither case was the liability for the cost of the volume for the year then expired, or, on the other hand, any unpaid subscriptions, taken into account. The total expense attending the issue of Vol. LIV. (for 1908), including printing, illustrations and delivery, has been 130*l.* 17*s.* 8*d.* No less than fifty plates and drawings were included in this volume, the greater part of the cost being kindly defrayed by the Wick Barrow Excavation Fund, the Norton Camp Excavation Fund, the Rev. F. W. Weaver, Mrs. Bramble, and Mr. F. Bligh Bond. Thanks are also due to the publishers of "The Reliquary," the Oxford University Press, Mr. Francis Bond, and the editors of "Somerset and Dorset Notes and Queries" for the loan of blocks. Various photographs and drawings for the volume were provided by Mr. F. Bligh Bond, Mr. H. St. George Gray and Mr. Reginald Weaver. In commemoration of the Diamond Jubilee of the Society a scheme was proposed at the Taunton meeting last summer for annexing the apartments in the Castle, formerly occupied by the curator, for the purpose of the extension of the museum and library. The details of this scheme were presented in the last annual report, when it was considered necessary to raise a sum of 650*l.*, including 175*l.* required for the improvement and reparation of Castle House, now the curator's residence. After various promises of donations last autumn a printed appeal was issued in the spring and sent out to all members. A fair response was made, and the fund now stands at about 320*l.* Every detail of the proposed alterations has been dealt with by the building sub-committee and their architect, and the general committee earnestly solicit further donations in order that this very necessary and desirable work may be proceeded with as soon as possible. The museum has been enriched during the past year by a steady flow of acquisitions, although there have been no large collections presented or bequeathed. The Wick Barrow Excavation and Lecture Fund has raised money sufficient to provide a good polished mahogany showcase for the relics found in the barrow and the model of the area. The prehistoric boat from Shapwick has now been placed on an ebonised stand, and when all moisture has evaporated the broken parts will be set up by means of iron brackets, &c. The Meare Lake Village relics found in the trial excavations by Mr. Arthur Bulleid last year have been presented. The Rev. A. M. Foster has presented the staff of office of the ancient borough of Newport, North Curry. Dr. and Mrs. Hopkins have added several new specimens to the collection of the brass emblems of Somerset village clubs. Mr. F. J. Barnes has given a cinerary urn from a large barrow at Portland. The old Sheriff's carriage of Somerset, bearing the arms of Barrett and the crest of Speke, has been presented, through the kindness of Mr. J. Standfast. Several framed portraits of Somerset worthies have also been presented. The Ham Hill collection of Roman and other antiquities has been added to by Mr. Hensleigh Walter. Mr. Kenneth Hayward has collected a large number of flint implements and flakes from the surface on Creech Hill and at Godminster, near Bruton, and sent them to the museum. Mr. Courtney Gardner has obtained a large series of shards of Roman pottery and a few other objects from Larkhill Lane Quarry, Preston Plucknett, Yeovil, which he has given to the county collection. The most valuable addition to the library during the year is the original chartulary of Mynchin Buckland Priory, of the early fourteenth century, bequeathed to your Society by the late Mr. J. Brooking-Rowe, F.S.A. Probably the most notable and complete archæological work, recently issued in two volumes, relating to Somerset, is Sir Henry Maxwell Lyte's "History of Dunster," now added to the library. Books relating to Wells and Glastonbury by Chancellor Scott Holmes, Canon Church, the Revs. W. Greswell and C. L. Marson and Mr. Bligh Bond, have just been published. Fairbairn's "Book of Crests" has been purchased for the library. The use of the library is steadily increasing. In connection with the manuscripts housed in the Exchequer of Taunton Castle belonging to the Manor, and other manuscripts in the possession of the Society, some useful work has been in progress. Mr. H. B. Sheppard, the steward of the Manor, has produced a valuable paper, entitled "Courts Leet and the Court Leet of the Borough of Taunton," which has been published and is obtainable at the price of 1*s.* a copy. The Rev. A. J. Hook has prepared a manuscript list of the contents of the Exchequer of Taunton Castle; and Mr. C. Tite has arranged for the compilation of a catalogue of the manuscripts contained in the Serel collection at Taunton Castle, a work on which Mr. A. J. Monday is already engaged. An interesting series of four lectures on archæological subjects—on two occasions by Mr. Bligh Bond and on single occasions by Mr. St. George Gray and the Rev. C. W. Whistler—were given at Taunton Castle during last winter in aid of special funds. The Taunton Field Club have for several years continued to use the Castle for the purposes of their conversaziones and lectures; and as long as space is available winter lectures at the Society's headquarters should be encouraged. Owing to excavations having been conducted in this county during the last few years on scientific lines, the Society has attained a high position in archæological field-work, a fact which has been commented upon from time to time in the Press. Among the most notable of these excavations are those which have been carried out at Glastonbury Abbey, the Glastonbury Lake Village, Wick Barrow, Castle Neroche, Small Down Camp, Norton Camp and Lansdown (the latter under the care of the Bath branch). Mr. F. Bligh Bond has continued the excavations at Glastonbury Abbey during the present year; and Mr. H. St. George Gray completed the first portion of his work at Charterhouse-on-Mendip in June last. Excavations under the charge of Messrs. Balch and Troup have also been in progress in Wookey Hole as opportunities have occurred; and Mr. Bulleid intends to dig two sections through Ponter's Ball this season. It is anticipated that excavations at the Meare Lake Village will be begun next year. The undertaking will be a costly one and will probably extend over several years; subscriptions are already being collected for this purpose, the list being headed by a gift of 100*l.* from Lord Winterstoke. The various owners of the greater part of the land comprising this lacustrine habitation have signified their approval that the antiquities discovered shall be exhibited in the museum and become the property of the Society. Messrs. Bulleid and Gray hope to be in a position to publish Vol. I. of the quarto monograph on the Glastonbury Lake Village next spring. It will be profusely illustrated and printed privately for subscribers. Through the munificence of Mr. George A. Wills, Stokeleigh Camp and Leigh Woods, on the Somersetshire side of the Avon, have been saved from threatened disfigurement by the builders who are overrunning that part of Clifton. Although the property will pass into the hands of the National Trust, a local committee of management is being appointed who will undertake the conservation of the camp. It is understood that an endeavour is being made by the National Trust to secure for the public an opportunity of purchasing a part of the Cheddar Cliffs. If the Trust is successful in its negotiations and the public support it by subscribing the purchase money, an important step will be taken towards securing the preservation of the beauty of the gorge and ending the quarrying operations which are so damaging its beauty and amenities. Various members have suggested the formation of sub-committees, or sections, throughout the county, specially to promote the study of local entomology and ornithology, and later on probably of other branches of natural history also. The committee will gladly welcome any suggestions bearing on this subject. Mr. H. St. George Gray, the assistant secretary and curator, having held office for the period of eight years in April last, the committee unanimously agreed to increase his salary by 20*l.* a year, and expressed their cordial appreciation of his services and of his zealous endeavours, and they desire to congratulate him on the warm appreciation of his work in connection with archæological excavations which is frequently expressed by antiquaries of high repute. The museum was visited by 7,902 persons during 1908, including 1,655 visits from members, an increase of 67 per cent. since the beginning of the century; 3,335 persons have visited the Castle during the first six months of 1909, which shows an increase of 11 per cent. compared with the same period of

Digitized by Google

last year. In rendering this report more complete it will be appropriate to record that the millenary of the foundation of the See of Wells was celebrated on June 22, with due pomp and dignity. At noon on that day the Prince and Princess of Wales arrived at the west door of the cathedral church, where they were received by the Archbishop of Canterbury, the Bishop of Bath and Wells, and the Dean and Chapter of Wells. In a forcible sermon the Primate reminded his hearers that just a thousand years ago, in Canterbury Cathedral, Archbishop Plegmund consecrated seven priests to be bishops, one of these being Athelm, the first Bishop of Wells. Subsequently there was an impressive ceremony at Glastonbury, where the Bishop of Bath and Wells and his co-trustees, Mr. R. Neville Grenville and Mr. A. F. Somerville, committed the future charge of the abbey to the Archbishop of Canterbury and an Advisory Council. The task of rendering the present ruins safe and of preventing their further decay is being undertaken by Mr. W. D. Caröe, F.S.A., whilst Mr. F. Bligh Bond, F.R.I.B.A., is still engaged in his interesting excavations at the abbey.

BRITISH CONSTITUTION ASSOCIATION CONFERENCE ON TAXATION OF LAND VALUES.

THE Chancellor of the Exchequer received on Thursday, July 16, the deputation appointed by the first meeting of the Conference, when the organisations represented included the following:—

Albion Permanent Benefit Building Society (Liverpool), Society of Architects, Auctioneers' Institution of the United Kingdom, Berks and Oxon Chamber of Agriculture, Birkbeck Bank, Birkbeck Building Society, Birkbeck Freehold Land Society, British Constitution Association, British Land Co., Ltd., British Law Life Insurance Company, British Savings Fund and Permanent Benefit Building Society (Liverpool), Building By-Laws Reform Association, Cavendish Land Co., Ltd., Chatham Cottage Owners' Association, Central and Associated Chamber of Agriculture, Central Permanent Benefit Building Society, Central Perpetual Benefit Building Society (Liverpool), Commercial Union Assurance Co., Ltd., Constitutional Permanent Benefit Building Society (Liverpool), Devon and Exeter Architectural Society, Eagle Insurance Company, Enterprise Permanent Benefit Building Society (Liverpool), Equitable Permanent Benefit Building Society (Liverpool), Estate Agents' Institute, Glasgow Property Owners' Association, Hand in Hand Permanent Benefit Building Society (Liverpool), Imperial Property Investment Co., Ltd., Incorporated Association for the Protection of Property Owners, Islington Permanent Benefit Building Society (Liverpool), Land and House Property Corporation, Ltd., London Friendly Institution, London Master Builders' Association, Leeds Permanent Benefit Building Society, Liverpool and District Property Owners and Ratepayers' Association, National Freehold Land and Building Society, Old England Permanent Benefit Building Society (Liverpool), People's Investment Co., Ltd. (Reading), People's Land, Building and Dwellings Co., Ltd., Provident Permanent Building Society (Exeter), Quadrant Insurance and Debenture Company, Royal English Arboricultural Society, Royal Institute of British Architects, Rural Labourers' League, Scottish Land and Property Federation, Seabrook Estate Co., Ltd., Second Equitable Permanent Benefit Building Society (Liverpool), Second Globe Permanent Benefit Building Society (Liverpool), Soho Permanent Benefit Building Society (Liverpool), Sunderland Working Men's Permanent Building Society, Surveyors' Institution, Universal Permanent Benefit Building Society (Liverpool), Wellington, Wiveliscombe, Milverton and West of England Building Society, West End Property Investment Co., Ltd., Western Suburban Permanent Building Society, Woolton Permanent Benefit Building Society.

Mr. Mark H. Judge, hon. secretary to the Conference, read the following memorial which had been prepared by the conference committee:—

Memorial re *Land Tax Proposals.*

To the Rt. Hon. Herbert Henry Asquith, M.P. (Prime Minister), the Rt. Hon. David Lloyd-George, M.P. (Chancellor of the Exchequer), and the other members of His Majesty's Government.

From representatives of organisations connected with land, and others.

This memorial sheweth:—

Your memorialists met in conference at the Whitehall Rooms on May 14 last to consider the land tax resolutions, when it was unanimously agreed to appeal to His Majesty's Government to withdraw from the Budget the proposals for the taxation of land values. (A report of the proceedings of the meeting is appended to this memorial.)

2. These proposals involve a violent departure from the principle which has hitherto exempted from taxation the capital as distinct from the income of living persons, and if adopted would constitute a most mischievous precedent, and seriously affect public confidence in relation to property which has always been regarded as secured to the individual owners by the guarantee of the State.

3. Any claim on the part of the State to a percentage of the increment value of land would inevitably decrease its value as compared with all other forms of property, out of all proportion to the extent of the prospective claim, while the adoption of such a method of taxation would induce a belief in the public mind that land would from time to time be singled out for further special burdens.

4. In practice the taxation of increment value would lead to extraordinary anomalies and injustice. For instance, land companies which buy land wholesale and sell retail are engaged in the very work of development which the Finance Bill profess to assist; yet as the Bill is framed the plots into which, as part of their business, they divide the land would, while they remained unbuilt on, be subject to the duty of ½*d.* for every pound of their capital value—which would be in effect to tax a tradesman on the stock which for the time being he had on hand and was unable to sell—in other words, to penalise him for trading in land.

5. Again, land cannot as a rule be placed on the market without considerable current expense for management, office rent, surveys, road-making, advertisements, auctions, &c. For payment of these expenses and for providing interest on capital borrowed and dividends on capital subscribed, practically the only source to which a land company can look is the difference between the book value and the selling price of the land in which it deals. Of that difference the Bill proposes to confiscate one-fifth, leaving four-fifths, out of which the whole of the administration expenses are to be met and the losses incurred in lean years made good. It is not too much to say that unless the sales are much more rapid and remunerative than is usual, no dividends would under these circumstances be paid by a land company, that most existing land companies would be absolutely ruined, and that this form of enterprise would become a thing of the past.

6. Some idea of the extent of the transactions of land companies may be gathered from the fact that one of the organisations represented by your memorialists has during its existence sold land to the value of about 5,000,000*l.* sterling. It is impossible to estimate with anything like accuracy the total amount of land sold through the operations of similar organisations, but there is no doubt that they have done a great and beneficial work in the direction of distributing land among the people.

7. From the shareholders' point of view land companies have not, as a rule, been very successful, and all chance of success would be gone if the increment taxation were imposed. The increased tax would not be the only new burden they would have to bear. Though their business is to develop land, the land which they have not for the time being succeeded in selling would apparently be regarded as "undeveloped," and be liable to the undeveloped land duty.

8. The proposed duty on land which is not fully developed is open to the most serious objection on the ground that it constitutes a charge on a hypothetical value which may never be realised, or which may only be realised at a period so remote as to result in a loss to the individual owner who during the period of waiting has received less interest than would have been the case had his capital been invested in Consols, or, indeed, as is often the case, no interest at all.

9. It is obviously unfair to subject to a new tax land which can only theoretically be used more profitably than at present. Such a tax might absorb a large part of the rent now derived from the land, and as it would be a first charge on the property the interests of holders of rent charges and mortgagees would be in many cases seriously jeopardised. It is perfectly well known that in many urban districts which are stationary, or where there is only a slow growth of population, there is no demand for land for building purposes for long periods, and the vacant land in such urban districts, if used at all, can only be used for allotment or agricultural purposes. Under these circumstances the income from the land might not be sufficient to pay the proposed tax and other existing charges, and thus the interest of the owner might be entirely absorbed.

Digitized by Google

10. One of the professed objects of the Bill is to increase building and cheapen houses. The proposed reversion duty would operate the other way. It is too often forgotten that the supply of new houses depends in the main on the operations of the enterprising builder who puts up buildings for which he thinks there will be a demand, and takes the risk of the market.

11. It is quite unusual for the man in want of a house to build the house for himself. The building-lease system suits the enterprising builder because it does not involve a lock-up of capital in the purchase of the fee simple. A reversion duty which would tend to increase the ground rents demanded and make owners more reluctant to grant such leases would clearly discourage builders, who would also, of course, be discouraged by the increment duty.

12. It is notorious that insurance companies, friendly societies, charity trustees, great public bodies and trustees for private persons hold an enormous mass of these reversions and also of mortgages of land. Their finance would be disturbed and their legitimate calculations upset by the proposed taxes, and a heavy blow would be dealt to the security of institutions in which a large part of the savings of all classes, and not least the working classes, have been directly or indirectly invested.

13. The proposed legislation would introduce complications and increase costs in connection with the purchase, sale and leasing of land, and is entirely opposed to the principle of free trade in land. It appears to be based on the idea that unearned increment on land is "regular, normal and progressive." This is very far from being the case. The value of land, as of other commodities, goes up and down, and though on the whole and in the long run there may be an increase, yet in large districts and for long periods there is often a steady decline.

14. The valuations and re-valuations suggested in the Bill would cause endless trouble, inconvenience and expense, and could never be put on a satisfactory footing.

15. The immediate effect of passing the Bill would be to depreciate the capital value of nearly all interests in land, probably to an extent much greater than would be shown by strict actuarial calculations.

16. This loss would fall on the persons who for the time being have the misfortune to be owners of land. Future purchasers would buy with their eyes open, and would make their offers with a knowledge of the liabilities they would incur. But although existing owners would be the heaviest sufferers, future purchasers would also be continually harrassed by the uncertainties of their position and the increased anxiety and expense which the possession of landed property would entail.

17. If the needs of the State should at any time call for a tax on increment value, it should obviously be *pro rata* on property of all kinds, and not on one class of property, whether that property be land or anything else. The adoption of the land taxation proposed in the Bill could not do other than induce a belief in the public mind that ordinary moral considerations were not in future to prevail in relation to property in land.

18. The land tax proposals of the Bill appear to your memorialists to be so unjust and impolitic that they venture to hope that this appeal to His Majesty's Government to withdraw these proposals will not be in vain.

The following members of the deputation then spoke:—

Lord Hugh Cecil, Mr. Herbert Michell (British Land Company), Sir William Chance (British Constitution Association), Mr. George Hubbard, F.S.A. (Royal Institute of British Architects), Mr. G. A. T. Middleton (Society of Architects), Mr. Edwin Evans (Incorporated Association for the Protection of Property Owners), Mr. Edward Bond (formerly M.P. for Nottingham). Mr. Alex. R. Stenning (President of the Surveyors' Institution) was unavoidably absent, and the remarks he would have made were handed in.

The Chancellor of the Exchequer, after complaining that the speeches to which he had listened consisted mainly of the sort of political arguments which he had heard for months, said that the advantage of deputations was that they enabled Ministers to hear at first hand from the persons interested what their view was. There were gentlemen there who could give him invaluable facts, but this they had not done. They had the whole of the facts at their command, and if they could demonstrate that any part of the Bill was unworkable, or inequitable, or unjust, he invited them to send these facts to him, and they should receive his careful examination.

GAS HEATING RESEARCH.*

(Continued from last week.)

Temperature Measurements.

ALL thermometers were on the Centigrade scale, and were constantly checked for accuracy. The flue temperatures were taken continuously by means of an electrical resistance thermometer and registered on a Callendar recorder placed on the wall in the main building. With proper attention it worked satisfactorily. The temperatures of the air in the experimenting room were determined by placing thermometers on all the walls in different positions, and hanging from the ceiling in the middle of the room—the bulbs of all being protected from direct radiation from the stove by placing each in the shadow of a piece of asbestos. The temperature of all gases passing through the various meters was taken by fixing thermometers into the meters above their water levels.

Calorific Values.—These were determined by means of a Boys' calorimeter, the water being weighed instead of measured, and the net values determined by weighing the water condensed over half-an-hour, and checking this by calculating the amount of water produced during combustion from an analysis of the gas. The latter figure was always a little higher than the former, the escaping products of combustion having a slightly higher percentage saturation than the atmosphere.

Coal-Gas Analyses.—These were all done on the "Bone and Wheeler" apparatus, in which all measurements were made at constant volume. Complete analyses for CO_2,O_2, unsaturated hydrocarbons, CO,CH_4,H_2, and N_2 were accurately made in about eighty minutes. Nitrogen was taken by difference. A typical analysis is as follows:—

CO_2	.14 per cent.
O_2	.41 per cent.
Unsaturated hydrocarbons	3. 9 per cent.
CO	6. 3 per cent.
H_2	39.04 per cent.
CH_4	33. 9 per cent.
N_2	16.27 per cent.

Gas-Rates.—These were estimated by noting the time taken by a cubic foot of gas to pass through the meter, correction being made by reducing the volume to 0 deg. C. 760 mm. pressure, dry. The pressure of the gas at the meter was allowed for.

The Meteorological Conditions.—These were obtained from the "Cecil Duncombe" observatory, close to the laboratory. The barometric pressures which were required for each volumetric calculation were got from a barometer in the analytical laboratory.

Experiments with the Open Gas Fire.

The stove used in the tests was of the simplest type and of normal size.

It consisted of seven Bunsen burners all connected with the same air and gas supplies, which were adjustable. Combustion took place within seven pieces of open fire-clay fuel, and the tips of the flames and hot products passed through similar material arranged across the top of the tube-like fuel. The stove had a thick fire-brick back, and the gaseous products passed out by means of a hole (4¼ inches by 1⅛ inches) into the copper flue already described. The whole was surrounded by a cast-iron framework. The fire-clay front measured 9 inches by 9 inches.

The air supply to the burners was so arranged that, after getting a distinct inner cone, it was adjusted until a slightly hazy inner cone was obtained. The flame was of such a size and shape that the outer cone, where combustion was being completed, very slightly impinged on the fire-clay fuel. The space beneath the fuel and round the burners was filled in so that the heat of the fire caused as little draught as possible through the fire with consequent loss of heat. The average gas consumption was 17 cubic feet per hour, and the net calorific value about 142 calories (571.4 B.Th.U's.).

The Estimation of Radiant Energy Sensible as Heat.

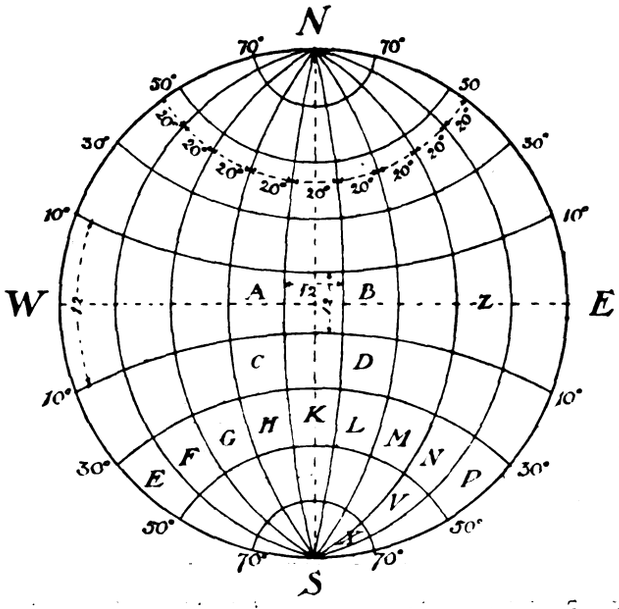
The chief work done since November has been the devising a method of estimating quantitatively the percentage of

* Extract from report of the Gas Heating Research Committee appointed by the Institution of Gas Engineers in conjunction with the University of Leeds, and consisting of Messrs. John Bond, J. H. Brearley, and Charles Wood, in co-operation with Professors Arthur Smithells (Chairman), William A. Bone, and Julius B. Cohen, of the University of Leeds, and Mr. E. W. Smith (Research Chemist), to the Institution of Gas Engineers, at their Annual Meeting held in London during June, 1909.

Digitized by Google

energy radiated as heat from the usual type of open gas fire. The two main points that presented themselves were:—Firstly, to decide on the most suitable, and at the same time a sufficiently accurate means of estimating the rate of reception of radiant energy at any given point; and, secondly, to so apply this means as to be able to determine quantitatively the total energy radiated from the whole area of the heated surface. Sir John Leslie, a pioneer in research on radiation, used a differential thermometer, consisting of a U tube with a bulb at either end, one of the bulbs only being exposed to radiation. This instrument is not sensitive enough, and, owing to the conditions of the work, would not be at all suitable.

Langley used an instrument which he called the bolometer.* This is very sensitive, portable, and receives radiation in every direction. Its principle is that of an electrical resistance thermometer, and is extremely simple to use. The radio-micrometer invented by D'Arsonval, and subsequently improved by Boys,† is also extremely sensitive, but not so handy as the bolometer. Its principle is that of the single thermo-junction and mirror galvanometer in one instrument.



The thermopile was the instrument eventually adopted, and, with proper precautions, has proved eminently reliable. It was of the Rubens type, and consisted of twenty junctions of iron and constantan wires in series, every alternate junction being shaded and at the room temperature, and the remaining junctions exposed to the radiation. An electric current is set up flowing from one to the other, proportional to the difference in temperature of the hot and cold junctions. The current was shown on a Paul single-pivot galvanometer in milli-volts. There was also a temperature scale on the galvanometer, which could be brought into use by putting 10 ohms into the circuit by means of a convenient switch. The temperature scale having a much smaller range of deflection, the milli-volt scale was always used. As the temperature of the room affected all the thermo-junctions to the same extent, no increased difference in deflection of the galvanometer was shown by variations in the room temperature. Nevertheless, the galvanometer was always brought to zero after each reading, and any slight differences in its internal resistance allowed for.

When a satisfactory method for registering the comparative radiation intensities at various points was found, additional means had to be adopted for estimating the total radiated energy emitted from the heated surface. It would have been possible to absorb all or most of the radiations; but the method would have been so long and tedious that at the end of the experiment there was every likelihood that most of the conditions of the experiment would have changed. The method adopted was as follows. It was known that energy would be radiated to every point from which the fire was visible. If, then, the radiated energy could be estimated the problem was solved. A promising instrument for making this measurement was found in a so-called radiometer designed by Professor R. H. Smith, and with this the experiments were made. This instrument consisted of a surface 12 inches square, composed of flattened copper tubes, connected in series, through which a current of water was caused to flow.

The tubes were close together and lampblacked, besides being protected by a lampblacked sheet-iron hood to protect the surface of the tubes from warm convection currents. Water was run through the tubes from a constant level and left the apparatus at a constant level, thus ensuring an even flow. Thermometers were so placed that the temperature of the water could be taken on entering and leaving the tubes. In using the instrument it was placed facing the source of radiation, so that the radiant energy falling on the 12-inch square surface of tubes might be absorbed, and the water passed through the instrument raised in temperature.

By taking the temperature of the water as it entered and left the radiometer, the average rise in temperature was obtained. From the average rise in temperature and the weight of water flowing through in a given time, the heat equivalent in calories of the radiations falling on the radiometer surface per hour was calculated. The size of the hemisphere upon which the radiations fell had to be determined. It depended on the size of the radiometer. This was 12 inches square. The circumference of the hemisphere should be exactly divisible by 12, and the radiometer in one position should be directly opposite the stove. It was decided that the semicircle forming the circumference of the hemisphere should be 108 inches in length, this being divisible by the width of the radiometer, 12 inches. There would then be four divisions on the equatorial rod, on either side of the centre division, or nine in all. If the half circle measured 108 inches, then, by calculation, the radius or distance from the centre of the stove to the radiometer surface or to the equator would be 34.4 inches.

When the points immediately above and below the stove (which, to carry the analogy with the earth a little further, may be considered as the North and South poles) were joined by ten meridians passing through each of the points marked off on the iron rod or equator, it was found that these lines converged at the North and South Poles at an angle of 20 deg. to one another. Parallels of latitude were then drawn 12 inches apart, starting from the poles. The surface of the hemisphere was then divided somewhat as follows, with each parallel 20 deg. above or below its neighbour (see fig.).

The Hemisphere Surface, in Front of the Stove, divided into 81 areas.

In the centre there is a 12-inch square, and there are both to the right and left of this square four equal squares in the same plane, making nine in all. Now the division N, A, C, S, D, B is exactly the same shape and area as each of the divisions to its right and left, and the parts of these divisions between the same parallels are equal, so that, for example, E, F, G, H, K, L, M, N, P are equal to one another. But the areas between the same adjoining meridians decrease as they leave the equator. It is found that these areas decrease they further they are from the equator in proportion to the cosine of the angle that the line joining the centre of the area to the centre of the stove makes with the line joining the centre of the stove and the equator.

So that the areas between
10° S and 10° N of the equator will be to the areas between 10° S and 30° S or 10° N and 30° N as 1 is to cosine of 20° =0.94.

Also the areas between
10° S and 10° N will be to those between 30° S and 50° S or 30° N and 50° N as 1 is to cosine 40°=0.766.

Also the areas between
10° S and 10° N will be to those between 50° S and 70° S or 50° N and 70° N as 1 is to cosine 60°=0.5.

Also the areas between
10° S and 10° N will be to those between 70° S and 90° S or 70° N and 90° N as 1 is to cosine 80°=0.174.

There are now 81 areas, each nine of which bears a relation to the remaining areas as 1 : 0.94 : 0.766 : 0.5 : 0.174 corresponding to the cosine of the angles of 0° : 20° : 40° : 60° : 80°.

Thermopile readings were taken at the centre of each of these areas. Then the amount of radiant energy falling on the areas was proportional to the thermopile readings, whether in milli-volts or degrees Centigrade, and to the size of the areas. The thermopile readings having been taken, all that was necessary was to multiply each reading by its proportionate factor, and the correct relative values of the radiant energy falling on all the areas constituting the hemisphere were determined. Now, by means of the Smith's radiometer, the real calorific value of the radiant energy falling on the centre area on the equator was determined,

* *Nature*, vol. xxv., 1881, p. 14.
† *Philadelphia Transactions*, 1889 A., p. 158.

Digitized by Google

and knowing this, the remaining values were calculated and totalled, giving the total radiated energy received on the surface of the hemisphere.

Radiation Determinations.

The first few experiments were preliminary, and were done for the purpose of finding the best conditions under which the determinations should be made and the precautions that must be taken that reliable results may be obtained. Considerable difficulty was caused by the fact that the coal gas from the towns supply would vary in its calorific value by 3 per cent. during the course of an experiment. Should a change take place during a radiometer determination, this might cause a serious error. If the calorific value rose, then the figures for the percentage energy radiated would be high. This is the probable explanation that is offered for the slight discrepancies that occur between figures obtained from experiments performed under otherwise similar conditions.

The first three experiments had for their object the determination of the percentage energy radiated above the floor level, *no* account being taken of that radiated to the floor. These had an average of 26 per cent. Subsequently, it was thought that greater accuracy would be obtained if the stove were raised some distance from the floor, in order that the heated floor should not affect the radiometer. This, and another change which will be indicated later, made a difference in the energy radiated of about 4 per cent., which would bring the above figure (26) down to about 22. This agrees with the mean of later determinations (experiments 6 to 11). The fan in the flue, used in the earlier experiments (1 to 14) for the purpose of maintaining a constant draught, was at half speed. The exit from the flue was nine inches square, and the volume of air passing up the flue averaged 1,500 cubic feet per hour. After the stove had been raised (40 inches from the floor), the total energy radiated from the stove was determined, and the mean of experiments 6 to 11 was found to be 31 per cent. of the total heat generated in the stove.

(To be concluded.)

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *American Architect*, still pursuing its study of architecture of the Southern States, is largely devoted to the early work of the now famous architects, Messrs. Carrère & Hastings, at St. Augustine, Florida, the greater space being given to the Flagler Memorial Church, a curious conglomeration of sketch-book architecture, in which the youthful designers seem to have been impressed with a desire to show all they knew, from the doorway of the Erechtheion to the Plateresco of Spain. More satisfactory, because more restrained, is the same architects' work in Mr. H. M. Flagler's house, whilst the designs for the Grace M. E. church and parsonage are simple and unaffected. An entirely satisfactory piece of work is illustrated in the "restoration" of the Governor's Room in the City Hall of New York by Mr. Grosvenor Atterbury, which has been brought back, if not to its original condition, at any rate to harmony with its primal design.

La Construction Moderne has some useful illustrations, plans, sections and elevations, with a description of a co-operative creamery at Bayeux, Calvados; a couple of views of modern Parisian doorways, one in the Rue Th. de Bauville, of which M. Prugnaud is the architect, and the other that of the Hôtel Chatham, by M. Decaux. There is also a charmingly satirical article on the changing of the Bay of Mont St. Michel into market gardens and the inconsequential proceedings of the "Grande Commission" appointed to consider the matter. Our contemporary, like ourselves, does not desire to see the famous Mount rising from the midst of a dish of vegetables—an island of toast in a sea of spinach.

Deutsche Bauzeitung gives further illustrations of the competition drawings for proposed police buildings on the Augustiner site in Munich.

Moderne Bauformen has taken advantage of the International Photographic Exhibition at Dresden to form a topic of the work of modern architects in that city. Herr Fritz Schumacher is selected as the designer of the scenery for "Hamlet" at the Court Theatre of Dresden, and other works of the same architect are a technical high school at Leipzig and designs for several memorials, of which the most striking is that to the honour of Ludwig Franzius in Bremen, overlooking the Weser, the regulation of which stream is due to him. There are also designs by Herr Schumacher for churches at Recklinghausen and Cotta, the latter a competition design, as some by other architects are also shown—Paul Bender, William Lossow & Max Hans Kühne, Schieling & Graebner, Oskar Menzel, Rudolf Kolbe. Numerous illustrations are included of the exhibition buildings for which several architects are individually responsible. Effective simplicity is the keynote of these designs, and there is an absence of that meretricious excess of florid ornament which has almost come to be recognised as the correct thing for exhibitions.

Der Profanbau continues to find out and show us some of the most striking modern work in German architecture, such as the municipal bath establishment at Iserlohn by Stadtbaurat Falkenroth, and a new tenement house in the Camphausener Strasse, Berlin, by Friedrich Blume, of Friedenau.

The *Engineering Record* gives us a valuable paper, read before the American Society for Testing Materials, by M. O. Withey, on the tests made in plain and reinforced concrete columns at the University of Wisconsin during the past year. Another useful article is that on the method of carrying out bearing tests for heavy foundation loads made under the direction of the architects, Messrs. Geo. B. Post & Sons, and the engineer, Mr. Amory Coffin, to ascertain the bearing power of the soil at the site of the new State Capitol at Madison, Wisconsin.

The *Architectural Record* has an illustrated account of that architectural nightmare, the New University Club in Chicago, a fifteen-storey, steel-framed, Perpendicular Gothic building, with internal Renaissance detail. The Exposition in Seattle is more satisfactory than many modern exhibitions, perhaps by virtue of the restraint imposed upon the designers by the lack of superabundance of funds. The house of Mr. Felix Peano, a sculptor who was his own architect, is strikingly peculiar, not to say eccentric. We hope Mr. Peano will not build another house, at any rate from his own design. The series of articles on "The Architect in History" now reaches the Dark Ages.

COMPETITION RESULTS.

THE Athy Urban District Council recently organised an open competition for the best plans of houses at 100*l*., 150*l*. and 200*l*. each under the Housing of the Working Classes Act. Mr. James F. Reade, A.M.I.C.E., has been awarded the premiums in the three classes.

The plans of Mr. G. H. Gadd, architect, of Bromsgrove, have been accepted for the new secondary school to be erected on the recreation ground, Bromsgrove. Six architects competed.

The plans of Mr. Herbert Norman, architect, of Northampton, have been accepted for the new Golf Club house at Harlestone, after a limited competition.

Messrs. Shayler & Swan, architects, of Shrewsbury and Birmingham, have had their designs selected for the proposed secondary schools for the Atcham Union. The assessor for the limited competition was Mr. H. T. Hare, F.R.I.B.A. In the course of his report Mr. Hare recommends that the number of architects invited in future should be at least twenty.

GENERAL.

Mr. John Archibald Campbell, F.R.I.B.A., died on Monday last after a few hours' illness in Edinburgh. Mr. Campbell was a Tite Prizeman, 1885, and a member of the Council of the Glasgow Institute of Architects. His work bore the impress of distinction, as, for instance, the offices of the Edinburgh Life Assurance Company in St. Vincent Street, Glasgow.

The Southampton Town Council have resolved to accept the offer of Mr. F. J. Burnett, offering to sell to the Corporation for the sum of 700*l*. Mr. Burrough Hill's collection of 228 oil paintings, water colours, pencil drawings, etchings and engravings of local subjects.

The Rector of Millbrook, Hants. (the Rev. G. G. Elton), has been asked to obtain the services of an architect and surveyor to report upon the condition of the church, and obtain a report of the estimated cost of the restoration.

Mr. Paul Waterhouse has been instructed by the North Riding Education Committee (subject to the approval of the County Council) to draw up conditions for competing architects to submit plans for the proposed High School for Girls at Saltburn, with accommodation for 120 girls.

FORTHCOMING EVENTS.

Saturday, July 31.

Architectural Association Camera and Sketching Club Summer Continental Excursion: Caudebec and District, July 31 to August 7.

Manchester Society of Architects: Visit to Stokesay and Ludlow, July 31 to August 2.

Wednesday, August 4.

Town Planning and Housing Exhibition: Lectures on "A Practical Town," by Councillor J. S. Nettlefold, and "The Story of London," by Mr. S. K. Ratcliffe.

Saturday, August 7.

Institution of Municipal Engineers: Annual General Meeting at Durham.

Monday, August 9.

Architectural Association: Annual Excursion, Headquarters at Cheltenham, August 9 to 14.

Tuesday, August 10.

Sheffield Master Builders: Return Visit from the Belgian Builders, August 10 and 11.

EXHIBITION OF STUDENTS' WORK, ROYAL COLLEGE OF ART, SOUTH KENSINGTON.

NATURALLY, on visiting this annual exhibition, we turn our attention first to the Architectural School, not only because we are principally concerned with architecture, but because at the Royal College of Art architecture has first to be made a subject of study by all entrants to the schools before they are permitted to specialise in any other branch of art. In the arrangement of the drawings for exhibition the principle has been adopted of selecting a limited number of works and hanging these with an adequate amount of room, so that the visitor is not surfeited with the sight of a large number, and is able to properly examine and appreciate those that he is shown.

In the designs of the Architectural School at the Royal College of Art one is struck with the importance attached and the attention given to the completion of a design by the thorough working out of the interior, and particularly of colour schemes of decoration; indeed some students appear to devote more time to this part of the design of a building than to plan and composition, possibly by reason of the fact that their study in the Architectural School is, as we have already said, compulsory, although their sympathies may be inclined more to other forms of art expression than building.

The designs by senior students from the first division of the upper school may be taken as illustrative of the work of those who are specialising in architecture, that is who mean to be architects, and is represented by a selection of four designs for a college chapel, and one for the interior of a council chamber. The designs for the chapel are all good and thoroughly worked out, that of the winner of the travelling scholarship, Mr. C. P. WALGATE, being of excellent character, if perhaps somewhat over florid except in the vaulting, which we should rather have seen treated with liernes as more in keeping with the feeling generally of the design. The detail of the canopy work is exceedingly good in design and workmanlike in its draughtsmanship. There is no attempt here at prettiness or trickery in delineation. It is, indeed, a feature of the Architectural School of the Royal College of Art that thoroughness is a dominant characteristic of the students' work. In all the designs for the college chapel, one drawing in each set, evidently compulsory, is a full-size detail of carving, drawn in black and white chalk on brown paper, and the details generally are well worked out. The design of Mr. H. L. OAKLEY, who wins the 6*l.* prize, is of a rather more strictly collegiate type, or, if you like, archæologically correct rendering of Perpendicular work, with fan vaulting, but although simpler in treatment than that of the scholarship winner is also an excellent design, one might even say on occasion more suitable for execution. The remaining two designs, that by Mr. W. T. BENSLYN, who has previously taken a 6*l.* prize, and that by Mr. A. B. ALLEN are also very good; and, as a matter of fact, there is no great degree of superiority in the designs that have obtained rewards over those that have not been so fortunate. The level of achievement is throughout of a very high standard.

The design for the colour decoration of a council chamber, by which Mr. H. F. CASTLE wins a 3*l.* prize, is good, but might possibly be better, the scheme of colour being somewhat too vivacious for the purpose. This, however, is better than a muddy effect, which might easily have resulted from a student's attempt at maintaining a lower and more sonorous key. As no other competitor's work is exhibited there is no opportunity for comparison with other renderings of the subject.

The five students, of whose work we have already spoken, represent the first division of the upper school. As illustrative of the work of the second division of the upper school, we have seventeen different treatments of the same subject, a town mansion occupying one side of an open square. This, a purely academic problem, is by no means an easy one for medium grade students, to whom it must necessarily be somewhat difficult to think in capitals or in a sufficiently grand manner for the essentials of the subject. Therefore, it is not surprising that many of the students whose work is shown have failed to produce properly dignified plans, and several have not risen to the level of the occasion in their external treatment. The interior decorative design is, however, well tackled by most, even if some have displayed a tendency to regard a town mansion as a box to contain costly apartments or halls. The majority of the students must have devoted far more time and study to their internal decoration than to their plan or elevation, or to both combined.

Mr. T. H. HUGHES has a good design with an interesting and effective plan, and the exterior is also both dignified and well composed with a grand central arrangement of columns and pediment. A porte cochère has apparently been deemed essential by several students besides Mr. HUGHES, but such a feature in almost all cases detracts from the dignity of a grand mansion. In this case the author has, as a practical point, spoilt its usefulness as well as the effectiveness of his treatment of forecourt

Digitized by Google

AT COMPTON WYNYATES, WARWICKSHIRE.—FROM A SKETCH BY BANISTER FLETCHER.

by adopting a wrong position for his carriage entrance, of which there should have been two, not one immediately facing the side of the porte cochère. Mr. H. RHODES has a plan which is lacking in architectural character and even in practical merit, although he has attempted by the arrangement of a circular hall to provide an occasion for a good piece of colour decoration. His exterior elevation, somewhat in the manner of KENT, is dignified if coldly and severely formal, but is relieved by some well-drawn figure sculpture. Mr. J. L. ROBINSON has produced a good design but illustrates it by only one elevation, thus avoiding what some of his fellow students have evidently felt not to be easy, the adequate rendering of the garden front. Mr. R. E. ROLLEY is represented by a design of some merit, whose details are better than the general scheme, the exterior in red brick and stone being somewhat lacking in dignity and not quite happy in proportion. His marble hall, although well enough *per se*, is scarcely in keeping with the feeling of the exterior, and can hardly be considered sufficient to turn a house into a mansion. Mr. W. M. KEESEY comes within measurable distance of evolving a good design, but his central feature both in front and back elevations is poor. Other designs not without merit are those of Mr. H. BROWNSWORD and Mr. J. F. GREENWOOD. There are two designs that are interesting because they reveal the fact that those we see exhibited are the work of their presumptive authors and not of the masters of the Architectural School. Mr. D. FRIEDLEY shows us an attempt to design a Gothic mansion, by the mixture of a rambling and involved plan with a curious jumble of motifs, principally German and Tudor, the whole adorned with eccentric quasi-mediæval lettering and verbiage. This gentleman has not yet comprehended architecture. The second youthfully original designer is Mr. F. GRISSELL, who has ignored the work of antiquity and produced a somewhat restless medley in red brick and white stone, which even the marble hall does not transform into a mansion. One is rather inclined to look askance on marble halls and imagine that they betoken a desire to attain luxurious decoration without great demands on the author's knowledge or powers of invention. Quite a mistaken idea, for though it is easy to specify the lining of walls with costly marbles, it is quite another thing to make a good design in marble, about the most difficult material it is possible for an artist to manipulate.

The examples of work by students in their first term or elementary course are excellent in their thoroughness, whether sketches of old work in the museum, studies of Classic and Mediæval detail, or designs based upon the work of antiquity.

The School of Sculpture and Modelling shows some admirable work, most of the examples like those in the Architectural School being parallel treatments of the same subject by various students. The travelling scholarship has been won by Mr. C. VYSE, with a "Design for a commemorative monument to a man of science (DARWIN), half size of execution. Subject: Time and Science Unveiling the Truth." Mr. G. LEDWARD, who has won the 6*l.* prize in a previous year, runs Mr. VYSE pretty close, but the latter's treatment, well composed, is the less conventional and more original. The 6*l.* prize for this year has been gained by Miss MAGGIE RICHARDSON with an admirable "Full-size study of a female figure from life," and the 3*l.* prize by Miss JESSIE LAWSON with a similar study. An interesting subject of which there are several renderings is a "Design for a panel over a door. Subject: Spring," with Mr. S. K. COPE's treatment of which we were particularly pleased.

Examples of the work of the etching and engraving class are shown in the same room with sculpture, and some beautiful prints show excellent results of the teaching in the school.

The School of Design exhibition is rather overloaded with numbers, and when in addition these comprise designs for varied applications, the result is somewhat bewildering to the visitor. Thus the winner of the

Digitized by Google

travelling scholarship, Mr. F. MOORE GORDON, is represented by drawings for brocades, room decoration, tapestry, printed cottons, pottery panels, manuscripts, &c., stained glass, wallpaper, a fire dog, and a marble tomb. Most of this gentleman's work is excellent, as are also his studies from old work, but his design for the decoration of a dome is hardly a success, either in colour or composition, whilst in some cases we think his work is surpassed by his less fortunate competitors; for example, Mr. R. C. WEST, who gains the 3*l.* prize, has some designs for stained glass which are very good both in colour and composition. The 6*l.* prize is taken by Mr. A. W. BELLIS, and amongst the other students who, although not prize-winners, have nevertheless done good work, we note Mr. TATTERSALL and Mr. WORSLEY.

The Evening School for Anatomy and Drawing from Life shows some excellent results of the peculiar system of instruction adopted. The skeleton, fully articulated, is posed in the same attitude as the living model, so that the student may readily grasp the relation of the bony structure to the muscles by which it is covered. Very important, too, are the rapid half-hour studies from life and the fifteen-minute sketches from memory, so that from the point of view of the decorative draughtsman admirable results are achieved.

In the School of Painting and Mural Decoration the good result of the study of anatomy and life is to be seen. The subjects set are mainly treated as sketches for mural decoration, and these in the main, are superior to the finished studies; but Mr. P. H. JOWETT, the winner of the travelling scholarship, has a good design for "Decoration over fireplace of library—oak setting," and Mr. R. R. GILL, who wins a 6*l.* prize, a good colour scheme in his "Panel for entrance hall of hospital—white setting."

Altogether the students' work of the Royal College of Art marks a satisfactory level of achievement.

NOTES AND COMMENTS.

THE necessity for a very clear definition in building contracts of the position of sub-contractors or independent craftsmen is shown by the lengthy litigation between Messrs. JOHN TANNER & SONS, plastering contractors, of Liverpool, and Birkbeck Bank Chambers, Chancery Lane, and Mr. GEORGE PERCY BANKART, the well-known artist in decorative plaster. Messrs. TANNER were general contractors for plaster-work at the Victoria and Albert Museum, and Mr. BANKART was employed in certain decorative work. It was claimed by Messrs. TANNER that they suffered damage, and it appears to have been admitted that they had done so, by the length of time that they had to allow Mr. BANKART the use of their scaffolding. On Mr. BANKART's behalf it was urged that there was no unnecessary delay on his part, but that the nature and importance of the work required the repeated alteration and offering up of models before Sir ASTON WEBB was satisfied that his ideas were properly carried out. Messrs. TANNER were not without experience of elaborate plastering, having carried out the work at Stockport town hall, and might therefore be expected to be able to estimate how long the work done by Mr. BANKART would take. Thus there does not seem to have been any fault committed by anybody. The case was tried before Mr. MUIR MACKENZIE, the Official Referee, and he decided against Messrs. TANNER'S claim on Mr. BANKART.

ST. GREGORY'S CHURCH, Kirkdale, Yorks., now being restored under the direction of Mr. TEMPLE MOORE, is of more than ordinary interest, from the remains of Saxon work therein. An old sundial with an Anglo-Saxon inscription, said to be the longest one extant; a coffin-lid of ETHELWALD, King of Deira, and a supposed coffin of St. CHAD are relics of more than usual importance.

MEMORIALS of great artists are always worthy of recognition, and it is pleasant to hear that the site of the house in which J. M. W. TURNER spent part of his boyhood at Brentford has been ascertained, and is now covered by Northfleet House. The determination of the connection is due to Mr. F. A. TURNER, librarian at the Brentford Free Library.

THE monument of UTCHA-HERU-A, recently added to the exhibition of Egyptian relics in the British Museum, is of considerable importance from the decorative gold ornaments with which it is adorned, a rare thing to find by the time that such statues come into a European museum, for gold is easily looted and melted, and it is a far cry to the date when UTCHA-HERU-A lived—between 1100 and 1000 B.C.

MR. W. GOSCOMBE JOHN, R.A., has completed the great memorial on which he has been so long engaged, to the honour of the late ROBERT ARTHUR TALBOT GASCOYNE CECIL, third Marquess of SALISBURY, and it can now be seen in its place in Westminster Abbey. Mr. GOSCOMBE JOHN has united in his work with the memorial of the late Marquess a record of the CECILS and the part they have played in English history.

MR. REES, of Cardiff, architect, has been fortunate in his appeal against a judgment obtained against him by the Ham Hill and Doulting Stone Company, Ltd., for the price of stone supplied to a chapel of which he was the architect. Mr. REES lost his first case on the strength of a written correspondence, from which it was made out that he ordered the stone and there was a contract between him and the stone company. He won his appeal by being able to show that this written agreement was not the real agreement at all, but that the effective agreement was a verbal one made some days afterwards, when Mr. REES disclosed the principals for whom he was acting. This is the point of the whole case. An architect must be careful in giving orders to disclose that he is acting as agent and not as principal.

IT is a pleasing feature of the first anniversary of the young and flourishing Concrete Institute, which we report elsewhere, that the hosts of the Institute included in their invitation their technical and commercial rivals in the cement manufacturing trade. This is as it should be. Esprit de corps amongst the members of any profession, trade, or calling is, to put it on the lowest ground, profitable to all the members. Men should put a little more of the feeling of sport into their business affairs, do their level best to beat the other fellow, and be the first to cheer and congratulate him when he has licked them. Architects especially have not as a rule sufficient sportsmanlike feeling in their professional affairs. If they had, we should see less of the unseemly bickering that so often follows the decision of a competition. Not that protests against unfair play are unsportsmanlike, but too often the grumbling and ill-will is but the manifestation of disappointed self-conceit. For this reason we favour the development in the Architectural Association of the athletic clubs. The young architect who has surpassed his fellows in the cricket field, the running path, or the rifle range, is surely the less inclined to grudge the palm of victory to his conqueror in an open competition for professional employment.

ARCHITECTURE: ITS TRUE PRINCIPLES.—XV.

By R. OWEN ALLSOP.

DOMINATION AND SUBORDINATION.

WE have considered the subject of unity in massing and generally concluded that while that mass dominates which has the largest bulk, there are means whereby, by position, certain enhanced values can be given to parts of an architectural composition. In fig. 35 the subordinate additions about the lantern seem to enable this to hold its own against the sheer mass of the tower.

However diverse may be the purposes of a work of architecture, however broken up its component parts, it is

Digitized by Google

nevertheless in purpose one thing in intention and to fulfil some main end. Hence the ultimate expression must have oneness. We have endeavoured to show how, if one feature be made plainly dominant (as, say, the lantern at Norwich) the dominating feature binds together the whole composition. It is not always possible in design to give the overlordship duly to that part which most merits the distinction; but unless we are to rest content with a kind of headless community, a variety of village, as distinct from a self-contained building, we must give the lead to some one feature or features. Common sense would seem to indicate that in a case like this, if what is the most important feature be so constituted as not to be effectually put into a position of true domination, the honour should, so to speak, go to the next in command, the next important feature.

In this case we can depend to some extent on increased work in any given part to give increased importance by attracting the eye to that point. This indeed is often the sole resource. In the case of street façades closely hemmed in either side, the whole of the composition consists in so cutting up and allowing the available superficies in this, which we may perhaps call two-dimension architecture—so that suitable architectural expression may be given. In such position a mere porch, large window, elaborate gable, or group of columns and pediment, may be frequently noticed as given the one dominant point in the scheme that the eye naturally demands, to save it from blank monotony and "over-all-alikeness." Many town sites, after allowing for practical considerations to be supplied, tax the resourcefulness of an architect to the utmost, and this is why, perhaps, the present run of street façades are not only not worth looking at, but positively repulsive. It is easy enough to produce fine effects in three-dimensioned architecture, but all praise is due to those who can so give the impression of beauty to a relatively flat façade that our attention is kindly arrested. The angle site gives more scope for treatment, and here the dominant angle turret or other treatment of the two meeting planes may form the keynote of the scheme. It requires wonderfully little to effect the object of providing one more prominent feature than another. We see many specimens of domestic architecture where the effect is

FIG. 35.—ELY.

lifted out of tameness and monotony by a small extra amount of thought or work bestowed on a bay window or windows, and fig. 36 may be instanced. It is a similar process to that of pictorial composition—the leading the eye to some central point of interest. It is clearly necessary to differentiate between this and the formation of a special point of interest and true dominating and subordinating of masses, and, further, between these and variety of treatment.

The right interpretation of the domination and subordination of mass is the giving to each its due weight and importance. This apparently simple affair necessitates in fact a nice sense of discrimination. We see the effect magnificently illustrated in the well-balanced cathedral, as we have endeavoured to show above. The success doubtless arises from the clearly perceived motive of emphasising the cross and the fact that the essence of the cross is the actual crossing and not the arms.

In default of some phonetic necessity for a supreme dominant object, or of the important member being, by its size or design, *ipso facto* the dominant object, we must needs fall back upon the more artificial method of architecturally creating a dominating mass. Manifestly the pro-

FIG. 36.—No. 17 FLEET STREET, LONDON.

ceeding is not so truly architectural. It becomes, however, an æsthetic necessity, if we are to avoid the tameness of monotony in mass. Monotonously equal values are to be avoided, either in weight of form or distribution of light and shade. We are only here following the well-understood laws of the artist and sculptor, and indeed of every kind of art. The point of special interest must be created; there must be variation in values, and there must be some law of variation either by contrast or by graduation. In composition—speaking of mass—it must be by varied "weight"; in an elevational class of design, such as city façades, the same must be apparent in what is, relatively, minor grouping.

It is interesting to inquire into the reason of this necessity. At first sight it might be thought that if a work of architecture is to have unity the first thing would be to give equal value to all parts—to equally and justly distribute thought and decoration so that there may (it might be argued) be a final oneness.

A great fundamental law of nature seems to be that there shall in nothing be equality. Equality and justness are not synonymous, since there may be justness without equality. At the outset then we are reasonable if we follow the dictates of nature and produce, or at least rest content with a state of unequal things. It is not necessary to give any further example than the stars with their sublimely varied distribution and brilliancy. Anything more horrible than the nightly reappearance of a geometrically regular pattern in the sky it would be difficult to conceive, unless it were a world laid out like a formal garden with absolutely symmetrical plant life, mathematically arranged with, also, all matter under the law of crystallisation. The

Digitized by Google

law of nature is variation, and there can be no variation without inequality—perhaps, more correctly, the fullest possible scope for variation demands inequality in the units that are subject to variation.

We are justified so far in emphasising the unequal, and if we consider that the parts component of a work of architectural design evidently vary in merit, worthiness, or dignity we shall have no hesitation in admitting the justness of inequality. Not to recognise and express this inequality would be unnatural, and would lead to the neglect of simplicity and truth.

The subordination of parts entails law and expresses order, the essence of which is correlativeness. The parts of an architectural composition may be related, or bound together, either (1) by mathematical symmetry, (2) by the symmetry of nature, or (3) by balance. Domination by weight of mass is powerful, but more so is subordination by relative position. Thus, all parts of a symmetrically *planned* capital refer to the axis of the column; hence the axis dominates though invisible and imaginary. As a result the regular figure of geometry has unity by the relation of its components to a centre, plane, or axis, and represents order where the irregular and amorphous is but shapelessness torn at random from infinite space. Concentric circles refer to a centre point; by eccentric displacement we may enhance the importance of each circle at the sacrifice of unity. As a consequence, regular geometrical figures are more pleasing than irregular figures, unless the effect is modified by specific design. Deformed geometric forms—as a defective cube, dented sphere or imperfect cylinder—are universally felt to be offensive. Meaningless masses become the personification of ugliness when they partake of the nature of a distorted elemental figure of geometry.

The reason, so far as concerns architectural design, seems to be the insubordination of parts—lack of relatedness. Fortunately the square and true-edged board of the architect insures automatically, to a great extent, due observation of the fundamental law of well-building—perpendicularity, and its complement, horizontality; and that eye must be warped indeed that preferentially creates distorted and expressionless main masses—deformed geometric solids. The 45° square further induces correlative planning. Thus, subordination by position becomes second nature, and elemental planning a variety of mechanical kaleidoscopy—true to angle and true to centre, base, and axis.

But, whereas by position we may subordinate, so by position we may also aggrandise and exalt. The eccentric circle, and the subtle (recondite) angle—as contradistinguished from the simple angle, such as 45° or 90°—gives more importance to the eccentrically and asymmetrically placed object; and this may be beneficial, as when to the regularity of a vase is opposed the irregularity of grouped flowers—geometrical, to broken, form—the rigour of mathematics to a natural *abandon* of carnation lily, lily rose.

The centre must perforce dominate the wings. As a principle, *omne trinum perfectum* is good. It is but another expression for unity, since three-in-one is understood. By observance of the laws that insure unity in multiplicity we may best avoid, in architecture "double composition," in life an *impasse* on the horns of a dilemma, with all that may imply.

(*To be continued.*)

EXCAVATIONS AT MAHASNA.

IN connection with the Egypt Exploration Fund an exhibition of antiquities found by Professor Ed. Naville, D.C.L., &c., Mr. E. R. Ayrton, and Mr. L. Loat at Abydos and Mahasna was opened on July 8 at King's College, London, and will close on Saturday, the 31st inst.

Last week Mr. Edward R. Ayrton delivered a lecture in the Hall of King's College descriptive of the excavations carried out during the past season on a prehistoric cemetery dating from before 5000 B.C. In his opening remarks he described the site and the way to reach it. After leaving the steamer at Alexandria or Port Said, a short railway journey brings one to Cairo, where a day or two is usually spent in getting the necessary papers from the Government. A concession to excavate is only granted on the condition that careful notes are made and finally published, and that the Cairo Museum shall have a right to a certain proportion of the objects found. From Cairo a railway journey of some nine hours bring one to Baliana; from here the site is about eight miles distant, the ride being made on donkeys across cultivated land.

The archæologists for the Egypt Exploration Fund commenced excavations in November, 1908, on the ancient site of Abydos. After they had been at work a couple of months a friendly (though not disinterested) Arab brought news that a predynastic cemetery was being plundered by the natives at El Mahasna, which lies about seven miles to the north of Abydos. Although his tales as to the booty which the thieves were nightly digging up fired the party's imagination, they felt it would be safer to judge of the site for themselves before asking permission to work there. Accordingly the party rode northwards, with the Arab as guide.

Although as far as could be judged from a cursory glance the place had been badly plundered, they decided to ask the Government to allow the party to test the ground at any rate.

M. Maspero, the Director-General of Antiquities, at once sent the necessary permit. On the evening of January 1 the cavalcade of camels and men (not to mention a small pup travelling in a basket) left the mud-brick house where the party had been so comfortably installed and headed northwards along the edge of the cultivation. Soon after nightfall tents were pitched beside the new site. The village of El Mahasna is built on the edge of the desert; to the south runs a long cemetery, which was excavated by Professor Garstang in 1899; here he also found a large prehistoric settlement with which the cemetery excavated last year was no doubt connected. The camp consisted of a tent for the directors, a kitchen tent, and two larger tents for the twenty-five men. The shallowness of an average grave of the predynastic period, and the absence of any considerable amount of surface rubbish, rendered a larger staff of workmen unnecessary.

The graves covered an irregular oval of desert some 200 yards long from north to south and from east to west about 150. A fair estimate of the original number of graves would be about 600, and of these about one-half were opened by the representatives of the Egypt Exploration Fund. The remainder had been too obviously plundered to repay digging from any point of view.

The earlier burials lay to the south on the sloping bank of a broad "wadi," and had been more or less covered over by drift sand which protected them from plunderers. The other graves (forming the majority) were dug on the flat surface of the desert; these had suffered severely. In fact the cemetery had been plundered on no less than four occasions. The first digging had evidently taken place in quite early times, and the surface had regained its natural flatness and gave no sign of the grave below. Yet most of these graves were absolutely cleared out, and the party considered themselves lucky if a single vase was found intact. The second plundering was shown by the shallow hollows which had not yet filled up; the third was still more marked, while the fourth was barely a month old—the graves standing open. This last plundering had taken place in the southern part of the site and had just touched the outskirts of the oldest burials. It was here the richest graves were found.

The cemetery is of importance from the fact of its complete isolation, so much so that not a single instance of a later burial was found in its area. The graves ran from the earliest period to the single-chambered brick graves of the early first dynasty, which were found on the extreme north. The sole difficulty with which the party had to contend was the hurricanes which are of frequent occurrence during January. Indeed, it was necessary to stop work on one or two occasions, so impossible was it to keep the burials clean until they had been photographed and recorded.

The earliest graves in the cemetery were shallow hollows in the desert, in which the body, probably wrapped in a skin, was placed in the crouched position which is typical of all predynastic graves. The only object placed in the grave was a single vase of black-topped red pottery, of which very numerous examples have been placed on exhibition at King's College. During the next period the skeleton was wrapped in a mat, while the graves were oval in shape and deeper. Slate palettes of rhombic shape for grinding eye-paint were placed in some of the graves, and of these also a considerable number are exhibited. In

Digitized by Google

one grave there were two black-topped vases, a large jar which contained grain, and a dish. Under it lay two ivory pendants and two slate palettes. Graves containing more than one body were the exception. In one such case the bodies were of a woman and a child in a large grave. Several vases of pottery stood at the head, and at the feet lay a clay gaming table with its pieces. Another body wore an ivory bracelet on each arm, ivory pendants beneath the left cheek, and a curious wooden figure lay on the body. All of these objects are exhibited at King's College. Some of the later graves of this period contained great quantities of pottery. In a typical instance a fine painted vase was placed near the face; fine vases were at the head and large rough jars (of which several contained grain) at the feet. Several burials of children were found—generally in rather large graves.

The next type of grave was oval, about six feet in depth, and was apparently roofed over. Laths were placed across the grave, on these were laid reeds, and on this again a plaster of mud. Some were about six feet in depth; those with a wooden lining come very late in the period and may even be of the first dynasty. The latest tombs in the cemetery belonged to the early first dynasty. They were lined with bricks, and a wooden lining either surrounds the whole of the burial or ceases at the larger vases. Only in a single instance did a pottery case enclose the body; this had neither top nor bottom, and, therefore, cannot be regarded as a true coffin. The pottery was placed outside.

It was in the earlier types of graves that the most valuable objects were found, the later graves being mostly filled with pottery. The grave that yielded the most valuable set of objects was that of two bodies, possibly a woman and a child, though the bones were too broken to yield any evidence. Before the face of the woman was a great mass of ivory bracelets. At the head were numbers of carnelian beads forming a necklace of about six hundred. A stone vase lay behind the body; two ivory vases were at the foot of the other skeleton. A comb and mud mace head were also found (the little ivory donkey being possibly off this latter), as well as ivory hair pains, the top of one of which has still an ostrich. At the end of the grave were several vases, two rhombic slate palettes and a group of ivory of great value. This latter was a long slim figure of a man with four wands pierced for suspension. At the head of the smaller skeleton were two or three ordinary vases and a very fine bowl with figures of hippopotami on the rim.

The gaming board found in another tomb is perhaps of most general interest. It is important to remember that the date is not later than 5000 B.C. The board was divided into eighteen squares; twelve pieces were found, two of which were larger than the others; it seems probable, therefore, that the centre row of squares was left blank at the beginning of the game and the men arranged with five small and one big piece on each side. It is not known how the game was played. From the same grave came seven hollow clay balls which rattle when shaken. These were evidently either cow bells or to wear round the waist.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE SUMMER EXAMINATIONS.

The Preliminary.

THE Preliminary Examination, qualifying for registration as Probationer, R.I.B.A., was held in London and the undermentioned provincial centres on June 14 and 15. Of the 178 candidates admitted, claims for exemption were allowed to the number of fifty-two. The remaining 126 candidates were examined, with the following results:—

District.	Number Examined.	Passed.	Relegated.
London	62	50	12
Bristol	9	6	3
Cardiff	9	7	2
Glasgow	8	7	1
Leeds	10	9	1
Liverpool	7	7	0
Manchester	14	11	3
Newcastle	7	7	0
	126	104	22

The passed and exempted candidates—numbering altogether 156—have been registered as Probationers, and are as follows:—

Aldous, C. F., Putney; Allen, G. A., Paddington; Allen, W. G., Bristol; Archbold, W. H., Yorkshire; Ashdown, A. J., Harrow-on-the-Hill; Atkinson, J., Lancashire; Bardens, S. H., Ipswich; Barrow, J. W., Morecambe; Baynes, E. S. A., Eccleston Square; Bennett, P. D., Birmingham; Bland, E. C., Northants; Booker, G. A., Sheffield; Booth, G. B., London; Bowmer, W. H., Oxford; Brewill, L. C., Notts; Brough, G. D., Balham; Brown, A. S., Slough; Brown, R. E., Dunedin; Bruce, J. C. C., Newcastle-on-Tyne; Brunelli, G. B. A. M., 2 New Square, Lincoln's Inn; Bush, D., Preston; Butcher, A. J., Weston-super-Mare; Butler, A. S. G., Kensington; Butler, W., Yorks; Cash, H. W., Harlesden; Cashmore, F. M., Hampstead; Catchpole, C. G., Ipswich; Chant, A. G., Lancaster; Clayton, C. L., Brighton; Cochrane, H. C., Dublin; Coldham, R. D., High Barnet; Copplestone, T. S., Exeter; Craske, C. W., Nottingham; Culverwell, W. L., Newport, Mon.; Day, M., Westbourne Park; Dodd, J., Newcastle-on-Tyne; Dodd, R. F., Isle of Man; Doherty, W. J., Londonderry; Edwards, E. H., Bradford, Yorks; Farmer, B., Siddington; Fausset, S. S., Belfast; Fenner, L., Hull; Fish, T. P., Bristol; Freaker, A. L., Clapham Common; Frear, E., Nottingham; Furner, A. S., Bristol; Gee, E., Liverpool; Goldschmidt, C., Withington; Gordon, D. J., Kent; Gray, J., Lanark, N.B.; Grellier, C., Epsom; Gunton, W. H., Blomfield Street; Hall, W. B., Folkestone; Harland, N. G., Lower Clapton; Harrington, C., Liverpool; Harris, M., Ealing; Hart, A. R. G., West Kensington; Hawes, F. L., St. Quintin Park; Higgott, S. B., Burton-on-Trent; Hoffmann, C., Bournemouth; Hofler, M. R., Pinner; Holaway, C. E., Chester; Holden, R. W., Lancashire; Holst, K., Basinghall Street; Holt, W. S., Middlesbrough; Hooper, E. L., Launceston; Hopewell, J. H., Eastbourne; Horsburgh, A. L., Streatham Hill; Howell, C. C., South Wales; Hudson, F. E., Streatham; Hughes, B., St. Swithin's Lane; Ingham, G. F., Elland; James, C. H., Gloucester; Jamieson, W. H., jun., Nottingham; Jay, E. P., Littlehampton; Jenkins, R. H., Hemel Hempsted; Jenkins, W. M., Port Talbot, Glam.; Jeune, B. H., Henley-on-Thames; John, D. H., Bridgend, Glam.; Johnson, A. G., Leytonstone; Johnson, R. S., Croydon; Johnson, T., Lancs; Jones, A. F., Salop; Jones, J. R., Penrith; Joslin, G. A., North Woolwich; Kessing, G. S., Melbourne, Victoria; Kitchener, A. J., Herts; Knights, R. E. V., North Kensington; Lait, L. H., Shepherd's Bush; Lambert, H., Surrey; Landy, H., Canonbury; Lawrence, J. H., near Neath; Lawton, W. V., York; Leigh, H. G., Clapham Park; Lemon, E. C., Southport; Lewis, R., Glam.; Lindsley, T. D., Wakefield, Yorks; Lowes, A. E., Newcastle-on-Tyne; Lutyens, E. J. T., Bedford; McCausland, C. J., Carshalton; Macgregor, J., Dunfermline; McLachlan, R., Lewisham; McLean, G., North Wales; Mant, F. G., New Square, Lincoln's Inn; Maxwell, H. P., Yorkshire; Maynard, F. J., Leytonstone; Mellows, J. S., Notts; Milburn, W. N., Carlisle; Millward, W. S., Cardiff; Mitchell, A., Scotland; Newton, W. G., Kensington; Nichols, C. E., Sheffield; Owen, G. B., Hampstead; Perrin, J. H. W., Reading; Pope, C. L., Southampton; Preston, E. C., Chester; Quarmby, G. F., Earl's Court; Ratcliff, F., Sheffield; Rayner, W. D. L., Chiswick; Reid, C. B., Vauxhall Bridge Road; Rhodes, H. G., Stockport; Rhys, H. L., Bridgend, Glam.; Ripley, C. G., Ipswich; Robertson, A. F., Perthshire; Robinson, P. G., Leeds; Ross, L. O., Belgrave Road; Scammell, E. W., Bristol; Seabrook, S. B., Ipswich; Shelmerdine, A. N., Liverpool; Shipley, R. R., Gateshead; Sibbitt, B., Liverpool; Silcock, A., Bath; Silcock, F. H., Bath; Smith, E. F., Walton-on-Thames; Smith, E. K., Muswell Hill; Soper, S. G., Brockley; Stephen, N. S., Chester; Taylor, W. A., Wandsworth Common; Teather, K. C. M., Cardiff; Tinker, R., Southport; Tolhurst, J. B. L., Beckenham, Kent; Tomlinson, L. D., Scarborough; Townsend, C. W., Staffs; Traylor, W. M., Newport, Mon.; Walton, N. A., Cheshire; Wardill, R. W., Chelmsford; Webber, W. K., Bournemouth; Whipp, J. R., Cheshire; Wills, T. L., Liverpool; Wilson, A., Fifeshire; Wilson, R., Falkirk; Winder, A. M., Oldham; Wooler, W., Manchester; Wray, E. J., Hertford; Young, C. J. M., Perth; Young, G. C., Perth.

The Intermediate Examination.

The Intermediate Examination, qualifying for registration as Student R.I.B.A., was held in London and at the undermentioned provincial centres on June 14, 15, 17, and 18, when 144 candidates were examined. The results are reported as follows:—

Digitized by Google

District.	Number Examined.	Passed.	Relegated.
London	87	36	51
Bristol	5	3	2
Cardiff	4	0	4
Glasgow	4	3	1
Leeds	19	8	11
Manchester	15	10	5
Newcastle	10	5	5
	144	65	79

The successful candidates, who have been registered as Students R.I.B.A., are as follows, given in order of merit as placed by the Board of Examiners:—

Hadwen, N. W., Yorks; Lenton, F. J., Stamford, Lincs; Smith, W., Nottingham; Hill, J., Newcastle-upon-Tyne; Hughes, T. H., South Kensington; Leroy, A. D., Hackney; Williams, L. E., Surrey; Paterson, J. W., Edinburgh; Winch, A., Leeds; Fowler, C. R., East Finchley; Hedley, G. E., South Shields; Johnson, B., Plymouth, Devon; Sturgeon, R. V., Whalley Range, Manchester; Creed, R., jun., London; Howard, P., Ashton-under-Lyne; Lawson, W., Gateshead-upon-Tyne; Brodie, J., Old Bond Street; Barefoot, H. J. L., Balham; Chetwood, H. J., Essex; Hill, H. O. W., Cheshire; Kay, J. W., Fife; Clarke, J. M., Preston; Letheren, W. H., Hants; Pearse, G. E., Shepherd's Bush; Jelley, F. R., South Wales; Hunt, S. G. W., Brighton; Russell, R. T., 11 Gray's Inn Square; Dewhirst, R. H., Leeds; Nicholson, F. W., Liverpool; Fish, T. P., Bristol; Hill, C. B., Yorks; Owen, G. B., Hampstead; Rogers, M. S., Manchester; Jones, H., Manchester; Allen, N. A., Liverpool; Barnes, V. S., Kent; Blount, W. S., Shepherd's Bush; Bloxam, O. A., Basinghall Street; Box, C. W., Lincoln's Inn; Brown, A. W. G., Edinburgh; Brunati, L., Middlesex; Carter, W., Sunderland; Dalgleish, K., Fenchurch Street; Dann, W., Gravesend; Garbutt, W. T., Bradford; Gibson, E. H., Harrogate; Hebblethwaite, B. R., Beckenham; Hedley, G. M., Northumberland; Hilton, R. M., South Kensington; Hooper, C. O., Earl's Court; Horniman, J. H., Hastings; Hulbert, F. S., Belgrave Road; Jenner, T. G., Bath; Knowles, B., Bootle; Leahy, W. J., New Southgate; Leech, W. L. B., Ipswich; Lushby, A. M., Fareham; Peters, K., Putney; Ridley, B. W., Nottingham; Ridley, G. W., Nottingham; Shepherd, H. J., Sheffield; Stanley, J. W., Manchester; Sutton, C. A. L., Nottingham; Thompson, W. H., Windermere; Webster, F. P., Sheffield.

Exemptions from the Intermediate Examination.

The following candidates, who had attended the four-year course of the A.A. School of Architecture, were granted exemption from sitting for the Intermediate Examination, and have been registered as Students R.I.B.A.:—

Adams, M. S. R., Chiswick; Pocock, P. W., jun., Surrey; Troup, F. G., Ealing.

Final and Special.

The Final and Special Examinations, qualifying for candidature as Associate R.I.B.A., were held in London from June 24 to July 2. Of the 132 candidates examined, seventy-six passed, and fifty-six were relegated to their studies. The successful candidates are as follows:—

Adams, P. T., Chancery Lane; Anderson, H. C., Heywood, Lancs; Antcliffe, W. C. (Special Examination), Fulham; Bartholomew, B. V., Walthamstow; Bell, W., Dundee, N.B.; Binning, A., Blackheath; Boddington, H., jun., 32 Emperor's Gate; Boss, A. H., Victoria Park Gate; Brazier, F. H., Cheshire; Bristow, C., West Norwood; Brough, W. J., Finsbury Park; Caminesky, P., Maidenhead; Carnelley, H., Hampstead; Carus-Wilson, C. D., Sevenoaks, Kent; Cathcart, W. D'Arcy, Bayswater; Cockrill, G. S., Gorleston; Constantine, H. C., Gower Street; Cook, V. C., Wolverhampton; Corfield, C. R., Birmingham; Dahl, J. L. S., South Hampstead; Dickinson, W. F., Cambridge Street; Dod, E. J., Liverpool; Edwards, A. L., Wimbledon; Edwards, A. H., Leicester; Ferrier, J. S., Edinburgh; Fitzgerald, G. E., Bedford Park; Fleming, H. S., Erith; Geen, C. A. (Special Examination), Lewisham; Gutteridge, R. F., Southampton; Hagell, F. W., Whitehall Park; Harvey, D., Hull; Henderson, A. G., Glasgow; Hotz, R., Wandsworth Common; Jarvis, J. W., Harrow; Jenkinson, J. M., Sheffield; Kaula, W., Earl's Court Square; Kenchington, H. (Special Examination), Bedford Row; Ludlow, W. H., Clapham Common; Lusk, T. Y. (Special Examination), Shepherdess Walk; McLean, A. J. C., Brighton; Madeley, C. S., Birmingham; Mair, J. T. (Special Examination), New Zealand; Maxwell, F. J. M., Bedford Park; Mellor, W. L., Manchester; Metcalf, C. B., Bradford, Yorks; Mitchell, G. A. (Special Examination), Acton; Mole, H. W., Newcastle-on-Tyne; Morgan, E. E., Crouch End; Morris, H. S. (Special Examination), Eccleston Square; Nicholson, R. H. (Special Examination), Sunderland; Orr, R., Dorset; Petch, E. S., Scarborough; Pett, H. M., Brighton; Pierce, R., Addison Road North; Purchon, W. S., Sheffield; Rainforth, S. H., Ravenscourt Park; Rose, C. H., Wimbledon; Ross, H. A., Shepherd's Bush; Sawyer, H. S., Bromley, Kent; Seccombe, H. E., Weybridge; Seddon, J., Strand; Shapland, H. P., Canonbury Square; Simpson, C. H., Putney; Smith, F. R. (Special Examination), Acton Hill; Stewart, D. W., Tottenham; Tasker, W. W., Newcastle-on-Tyne; Turnbull, A., Sunderland; Unwin, H., Wigan; Vey, G., jun., Chiswick; Waller, H. (Special Examination), Gower Street; Warlow, H. G., Sheffield; Watt, J. D. D., Falkirk, N.B.; Williams, G. H., Windsor; Wills, J. B., Highbury Terrace; Wingrove, G. C., Newcastle-upon-Tyne; Young, J. G., Alloa, N.B.

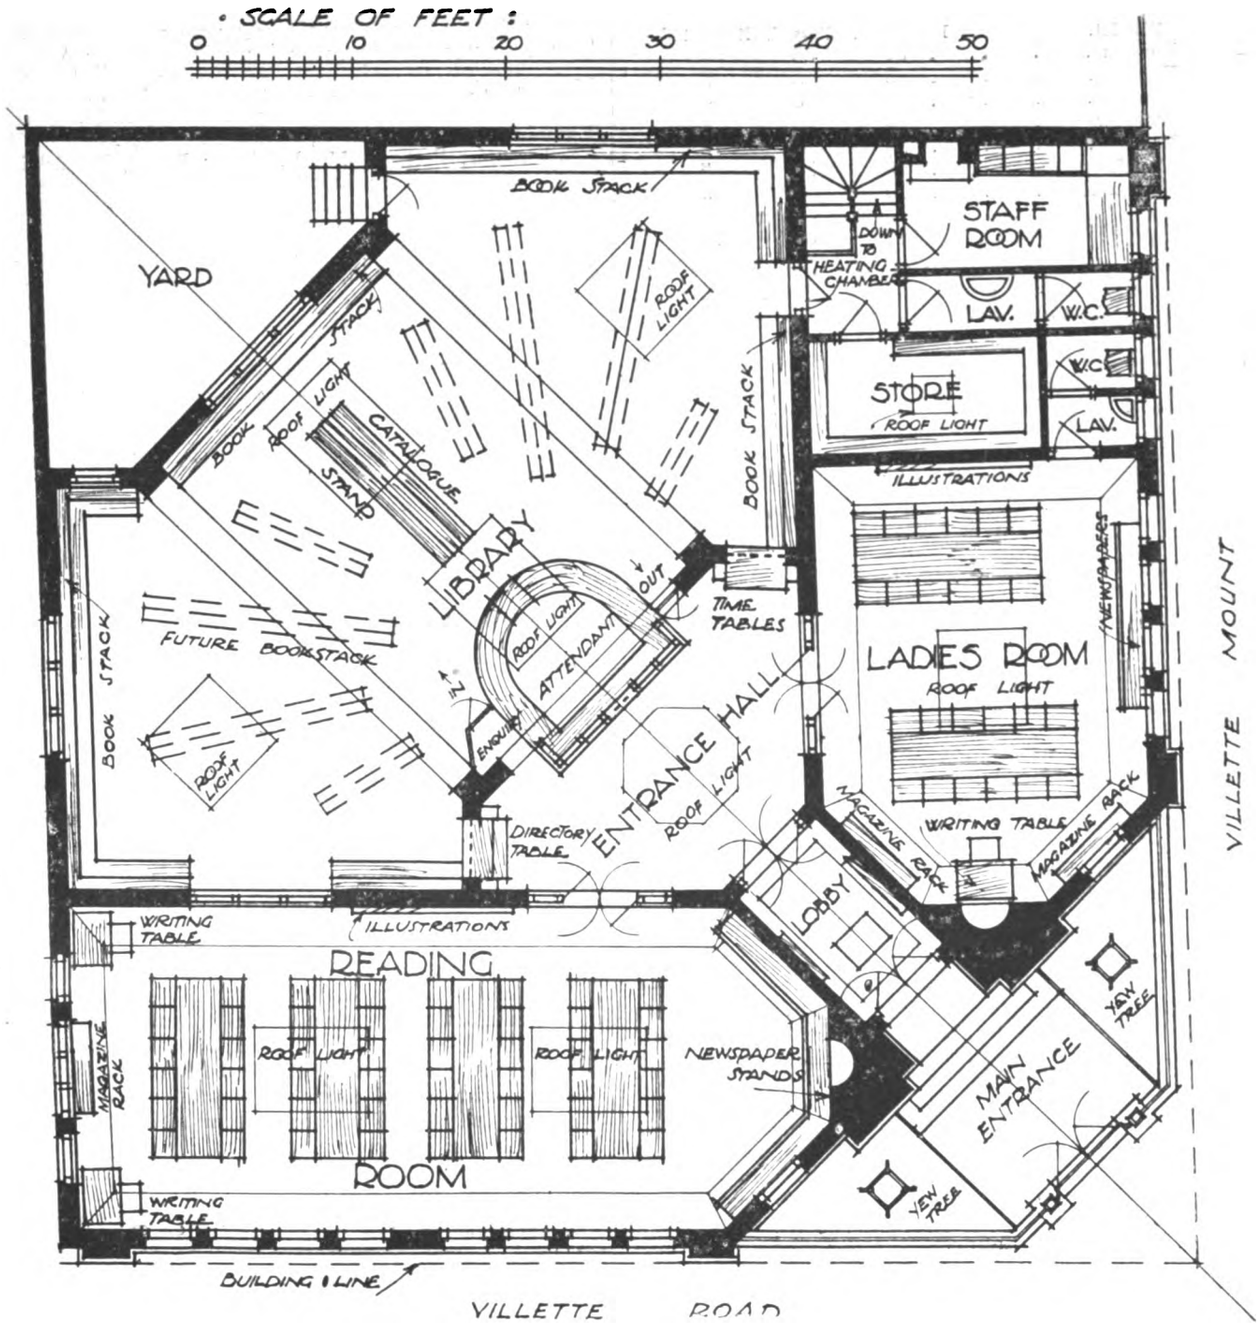
The following table shows the number of failures among the fifty-six relegated candidates in each division of the Final Examination:—

I. Design	44
II. Principles of Architecture	50
III. Building Materials	16
IV. Principles of Hygiene	22
V. Specifications	25
VI. Construction, Foundations, &c.	40
VII. Construction, Iron and Steel, &c.	28

ILLUSTRATIONS.

LIVING ARCHITECTS.—NO. 14, MR. REGINALD BLOMFIELD, M.A., A.R.A.' F.S.A., V.P.R.I.B.A.

MR. REGINALD BLOMFIELD is known not only for his excellent and scholarly architectural work, but as Professor of Architecture at the Royal Academy, and a charming writer. He has recently been elected vice-president of the Royal Institute of British Architects.



NO. 15, MR. PAUL WATERHOUSE, M.A., F.R.I.B.A.

IT is not always an advantage to have had a great man for one's father, but Mr. PAUL WATERHOUSE has made his mark independently, and in some of his recent work has evinced a scholarly and refined power of design that marks individuality. The best feature of Mr. WATERHOUSE's work is that it continually improves. We have intentionally linked in our series of cartoons Mr. REGINALD BLOMFIELD and Mr. PAUL WATERHOUSE as exponents of scholarly refinement in architecture.

BIRMINGHAM UNIVERSITY.—GENERAL VIEW FROM REAR—THE GREAT HALL—ENTRANCE HALL—INTERIOR OF GREAT HALL.

THE University of Birmingham sprang from Mason College, which was founded in 1870 by the late Sir JOSIAH MASON. Thirty years later it was absorbed into the newly-created University. In 1900 Messrs. ASTON WEBB & E. INGRESS BELL were instructed to prepare sketch plans of the new buildings. In February of the following year the Birmingham Architectural Association wrote to the authorities requesting that "having regard to the local interest and great importance of the new University to the Midlands, a competition among architects be arranged for the proposed new buildings on the lines of that conducted for the Victoria Law Courts, in which the sketch plans drawn up by Mr. WATERHOUSE were supplied to competitors, and that the sketch plans which we understand are being prepared by Messrs. WEBB & BELL should similarly form the basis of such competition." The Council replied that in their opinion the principle of selecting designs by competition could not be advantageously adopted in the case of the University. At the first annual meeting of the Governors in January 1901, when the appointment was formally made, it was announced that the donations promised amounted to about 410,000*l*., including the value of 25 acres of land given by Lord CALTHORPE. It was decided to erect in the first instance a University Hall (150 feet by 75 feet) and three departmental blocks for engineering and metallurgy, two on the west and one on the east side of the hall, the whole fronting to the arc of a semicircle with University Road as diameter, together with a power station. Since then

Digitized by Google

GROUND PLAN OF LIBRARY, HENDON, SUNDERLAND.—EDWARD CRATNEY, Architect.

two further blocks have been undertaken, one at each end of the semicircle, as well as the Chamberlain clock tower 200 feet high.

The entrance hall is 50 feet square and 100 feet high. The floor is of Pentelikon and Sicilian marbles, and above is a circular gallery carried on marble columns. Overhead is the dome, 50 feet in diameter and 92 feet high from the pavement of the hall. Opening off the south end of the entrance hall is the great hall 150 feet long, 75 feet wide, and 65 feet to the crown of the semicircular plaster ceiling. This ceiling is enriched with the arms of the University by the Bromsgrove Guild. The walls are panelled in wainscot, and the gallery balustrade and the pilasters carrying the ceiling ribs are in buff terra-cotta. At the south end of the hall is the platform, with the usual retiring rooms on each side. Above each side of the platform may be seen the pipes of the organ made by Messrs. NORMAN & BEARD, Ltd., London, in the construction of which an extraordinary amount of care had to be taken. The general contractor was Mr. THOMAS ROWBOTHAM.

BRANCH LIBRARY, HENDON, SUNDERLAND.

THE building has been planned with a view to working the library with as small a staff as possible. The principal rooms are grouped round the entrance-hall, and consist of lending library, general reading-room and ladies'-room, with the usual complement of staff-rooms, stores, &c. The delivery counter is so placed that the librarian has direct supervision of each department. The library will be arranged on the "safe-guarded" open access system. The elevations are designed in a quiet treatment of Free Renaissance. The walls are faced with Ormesby brick and Windy Nook stone dressings, and the roof covered with blue Welsh slates. The floors of the main rooms are laid with maple wood blocks. The whole of the interior fittings are executed in oak. The building was designed by and carried out under the supervision of Mr. EDWARD CRATNEY, architect, of Messrs. DAVIDSON & CRATNEY, of Wallsend and Sunderland, whose design was selected in competition. The contractor was Mr. Jos. HUNTLEY, and the stonemasons MCMILLAN & SON, both of Sunderland. The carving was executed by Mr. CHRISTIAN NEUPER, of Newcastle. Messrs. EMLEY & SONS, Newcastle, were responsible for the heating and wrought-iron gates, and Messrs. SPITTAL & CLARK, Birmingham, for the electric-light fittings and ornamental metalwork. Messrs. ROBSON & SONS, Newcastle-on-Tyne, executed the delivery counter and screen, and Mr. F. COOKE was clerk of works. The whole of the fittings and fixtures have been designed by the architect and executed by the contractor.

INTERIOR OF THE CHURCH, GODALMING.

GODALMING.*

GODALMING is a town of high antiquity. It is mentioned in the will of Alfred the Great in the year A.D. 900; he gave it to his nephew Æthelwald, with the manor of Guildford and other property in Sussex. It is on record that the King of Denmark possesses two pennies of Ethelred that were coined at Godalming, and there is a street named Mint Street in the town at the present time. The principal industry was that of cloth-making. The former corporate seal of the town bore the device of a woolpack, and this has been perpetuated in the arms of the borough that were granted near the end of the nineteenth century. This trade once flourished, not only here, but at Guildford and Wonersh. It is said that weaving was carried on here as early as the reign of Richard II. (1377); the industry declined in the seventeenth century, and a petition was presented to Council dated November 26, 1630, by Philip West, John Perior, Joshua Perior, Lawrence Hackman, John Woods, Robert Chitty, Henry Chitty, Henry Monger, Nathaniel Webham, Timothy Chitty, and others; and these were described as clothiers of Godalming. After stating their grievances, the throwing of 1,400 poor people out of work, &c., they conclude by asking for an order for venting their cloths. This distress was brought about by their own careless trust in the stability of their contractor, Samuel Vassall, who being restrained of his liberty, and no other merchant coming forward to take it up, they were utterly disabled. On December 30 they presented a second petition "of distressed clothiers of Godalming and Wonersh to the Justices of Peace of County Surrey." According to Sir William Elyott the poor people of Godalming and Wonersh alone, who depended on the clothiers, amounted to 1,100, besides others in neighbouring parishes who numbered 3,000. Aubrey in his comment on this distress says:—"The decay, and indeed ruin of the trade, was their avaricious method of stretching their cloth from 18 yards to 22 or 23 yards, which being discovered abroad, they returned the commodity on their hands, and it would sell at no market."

Since the "decay of the blews" trade has opened up in other directions, such as the manufacture of stockings by framework knitters, of whom there were a large number in the eighteenth century. Bargate stone is now obtained locally in large quantities, and is used extensively in the erection of churches and other buildings.

According to the Report of 1835 on Municipal Corporations, the borough claimed to have a charter of 28 Edward I., but none of the inhabitants had ever seen it, and no allusion to it could be traced in any existing documents. There seems to be no doubt that this charter is the one that was granted on June 7, 1300, to Simon Bishop of Salisbury. This conferred a market at his manor of Godalming on Monday in each week, and a yearly fair on the vigil, the feast and the morrow of SS. Peter and Paul. Under the Bishops of Salisbury the inhabitants were exempt

* Read at a meeting of the Upper Norwood Athenæum by Mr. T. C. Thatcher.

Digitized by Google

from toll on their goods and merchandise throughout the kingdom, freedom from service at the shire and hundred courts other than their own, and the right that, subject to certain exceptions, writs should be served on them by their own bailiff; the king's servants had no right of entry into the liberty of the manor or hundred.

The precise limit of the market town is not known, but there must have been some recognised area, as fines were inflicted for carrying on manufactures outside the town. There is a notable instance of this in the persons named Glover, who in 1440, 1441, 1452 and 1483 were fined for carrying on their trade of whitening leather outside the market town.

It is curious to note that on the east side of Church Street there was a house named Glovers; this was in the manor of the Rectory of Godalming, which was distinct from that of the town, and belonged to the Dean and Chapter of Salisbury. It is possible, therefore, that being outside the town, it did not enjoy the same privileges as those inside.

The old Hundred House stood on the site of the present market house, and it is probable that the Hundred House was adopted as the market house of the new Corporation. The present town hall was built in 1814.

Mr. Ralph Nevill in his able work deals largely with the charters; and I would like to do so also, but time does not permit. To put it briefly, the charter was granted January 25, 1575, by Queen Elizabeth. The next muniment in date was granted by King James on May 30, 1620. Clause 26 lays it down that no "inkeeper, alehouse keeper or tipler" shall entertain any inhabitant for more than half an hour either at one time or altogether on the same day, and fixes nine at night as closing time.

The town still possesses a copper toll dish shaped like a pipkin, and inscribed "Tolldish 1800," and also a constable's staff marked "V.R." There are also two large staves; the larger, which is carried by the bailiff, is painted all over, and has an escutcheon with the arms of England, Ireland and Scotland, with an in-escutcheon of Hanover, and the initials J. H. G. (John Hall Grinham, Warden), and the date 1810. It is 6 feet long, and tapers from 1½ to 1¼ inches in diameter, with a large gilt knob. The smaller, dated 1859, is of mahogany, or some similar wood, 4 feet 10 inches long, with a plain silver head 2½ inches long, an inscription in capital letters "Ex dono thome Cowper, gent.," and on the top, "Guardian-de-Godalmyng 1589"—this was used doubtless by the mayor.

The warden and assistants were superseded by a mayor, aldermen and council, under the Municipal Corporation Act of 5 & 6 William IV. cap. 26 (1835), and the borough was extended in 1892. It was then that a new coat of arms was granted, and the use of the old seal made in 1749 discontinued.

We will now leave the dusty charters, and turn towards the lighter side; and though I can only touch upon this, I would strongly advise any here present to read Miss Gertrude Jekyll's book "Old West Surrey," and also Thompson's "Picturesque Surrey." To begin with, it was in the King's Arms Inn that Peter the Great and his suite lodged in the year 1698. The bill of fare for this party, twenty-one in number, was pretty considerable; for instance, they had for their breakfast half a sheep, a quarter of lamb, ten pullets, twelve chickens, three quarts of brandy, sixty-nine quarts of mulled wine, and seven dozen eggs, with salad in proportion; their dinner, three stone weight of ribs of beef, a fat sheep, a lamb, two loins of veal, eight capons, ten rabbits, three dozen of sack, and a dozen of Bordeaux. In the year 1814 the Allied Sovereigns and their suites were entertained in this place, on the occasion of the overthrow of Napoleon.

The title of the inn is reminiscent of Charles II.'s visits to his hunting lodge, which is said to have been a timbered house, but now pulled down, and stood in Bridge Street. It is here also that the coaches conveying convicts would be driven into the yard, the gates would be closed, and the armed guards would let their charges out for a short rest and some food. These unfortunates were to be transported, Portsmouth being the port of embarkation. Again, it was no uncommon thing to see a coachload of sixteen jolly sailors, four inside and twelve outside, just paid off from some man-of-war, who had been from three to four years at sea, on their way to London town to spend their money—which they soon did. They carried a good store of liquor to keep up their spirits on the long journey. Such loads of seafaring men sometimes proved a danger to the coaches. They were so much accustomed to being swung about at sea, that when the coach lurched and swayed on a bad bit of road, or downhill, they let themselves go and swayed with it, instead of poising the body to counteract the movement of the coach, and the consequence was that several of the coaches were overturned.

Westbrook House, now a "Home of Comfort" for epileptic women, was originally the old manor house, long the property of the Oglethorpes, who settled here from Yorkshire in the seventeenth century. But previous to this it was owned by Nathaniel Godbold of the "Vegetable Balsam" epitaph which is to be seen on the wall of the south chancel. General Oglethorpe was born in 1698. The death through small-pox of one of his acquaintances, by name Castell, whilst in prison at the Fleet, drew the general's attention to the state of this place, and also to the Marshalsea. An inquiry was made, and the result was so horrible that reforms were at once instituted. He also founded the colony of Georgia in 1733, the last of the original thirteen United States to be formed; and one clause in the charter reads "no slaves were to be introduced." There are many other points in this man's life that are worthy of being recorded. He died in 1785. His philanthropy was celebrated, and is enshrined in a famous couplet in the second epistle of the "Imitation of Horace," by Pope:—

> "One, driven by strong benevolence of soul,
> Shall fly like Oglethorpe from pole to pole."

There is a very fine specimen of ornamental brickwork of the seventeenth century; it is situated in the High Street, and bears the date of 1663. On making inquiries of the tenants I was assured that it had not been materially altered in any way.

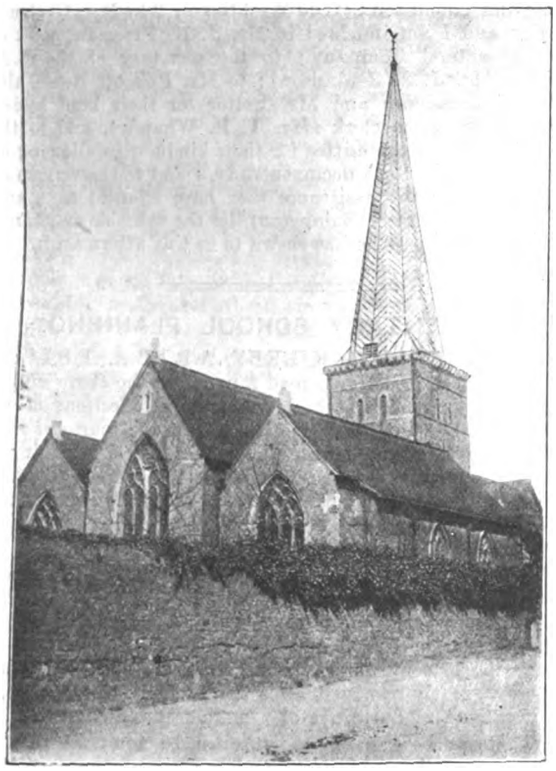
Smuggling was pretty prevalent in these parts. The "stuff" would be carried up from the coast by pack-horses, and left in various hiding-places on the road; but, should any villager come across any such hiding-place, he was by old custom allowed to chalk-mark certain of the goods for his own use—the smugglers leaving such marked goods alone, it being understood as a bargain, in consideration of the discovery not being reported. It was no uncommon thing in those days for the squire and farmer to wink at this traffic, to find a small keg of spirits or a parcel of lace left at their doors, as a return for the loan of the horses taken from the stables during the night, and even the parson was not exempt from such attentions. There is a good story told by Miss Jekyll about a squire new to the country—it was in the hills near Dorking, in the early part of the nineteenth century. One morning before he was dressed his valet brought him an urgent message from the bailiff to say that he wished to see him. The master said he must wait, as he was not dressed. The message was sent up again still more pressingly worded. "Well, send the fellow up," said the astonished squire. The man came in with a mysterious air and watched the servant out of the room, and then said in a hoarse half-whisper, "There was a run last night, sir, and I've marked four." The squire had no idea of what the information meant, and on being enlightened burst out indignantly, "But I can't have anything to do with smuggled goods; why, I'm a magistrate. How dare you come to me with such a suggestion?" The bailiff stood his ground and said, "If you'll take my word for it, sir, if you don't do as others do you'll have trouble." The squire continued to protest; the bailiff said, "Well, sir, will you ask the parson?" He did so, and the rector's answer was, "If you wish to live in peace with your neighbours you had better fall in with the custom of the country."

Godalming, like all other places, has its own folk lore and traditions, and it is supposed to be very partial to cats, if we are to accept the following lines:—

> Godalming for cats;
> Guildford for bulls;
> Chiddingfold for drunkards;
> Haslemere for fools.

The favourite device here for the token is a "malt-shovel."

Godalming Church is dedicated in honour of St. Peter and St. Paul. Mr. Prescott Row, in his very interesting work on Godalming (Homeland Series) refers the reader to a monograph by Mr. S. Welman, a local antiquary and architect. He then states:—"A special feature is the series of conjectural restorations of the church, as there is reason to believe that it existed during successive epochs—the Saxon church of the early part of the eleventh century, the Norman church at the time of Flambard, the Early English church of the thirteenth century, the Decorated church of the fourteenth century, the Perpendicular church of the fifteenth



Digitized by Google

and sixteenth centuries, and the 'churchwardenised' church, this latter from actual old prints, of the eighteenth century and the beginning of the nineteenth."

The Saxon church was a very humble structure, consisting of aisleless nave and chancel. To find out the parts belonging to this church, you must go up into the roof space of the nave, where they are hidden away. Yet it is stated that the whole lower storey of what is now the central tower, and probably the more easterly part of the nave, still enshrines the actual masonry constructed by our Saxon ancestors.

Norman church, twelfth century. The original nave was apparently left untouched, but a new Norman tower—sturdy and squat—was raised on the actual wall of the old Saxon chancel. At the same time a new chancel was built to the east, to meet the growing needs of the church, and also to give the Norman priest more room for his more ornate ceremony. Traces of its original round-headed windows were discovered during a repair to the chancel in 1867, and more fully laid open in a restoration of 1879. These have been carefully preserved, but unfortunately the fine old Saxon arch which for over 800 years had separated the tower from the nave was destroyed in the restoration; this so-called restoration has much to answer for. North and south transepts were afterwards added at a later period, either by Flambard or one of his successors, and the Norman church was complete.

In the thirteenth century chantries were added on either side of the chancel, and the nave was enlarged by the addition of aisles; at the same time the tower was raised by a storey, and was probably crowned by a spire.

THE CHURCH, GODALMING.

It was in the fourteenth century that the spire was built of timber covered with ornamental lead work, and it is without parallel in Surrey. It is said that these were common after the middle of the thirteenth century, but have mostly disappeared. Mr. Welman gives a very good reason for their disappearance. "We shall want some lead," writes the Lord General to his cornet; "the steeples have plenty."

In the fifteenth and sixteenth century epoch the nave and its arches were extended a single bay to the west; new roofs and ceilings were inserted, and the windows were enlarged and remodelled.

The Churchwarden period (seventeenth and eighteenth century). This was a glorious time for them, and was typical of the usual monstrosities—the erection of galleries and square box pews (where the said wardens could go comfortably to sleep), the panelling over of walls, and the boarding of roofs.

The church has undergone two restorations—in 1840 when the nave was lengthened, and in 1879, during the incumbency of the Hon. and Rev. Canon Broderick, at the hands of the late Sir Gilbert Scott, assisted by the advice of Mr. Ralph Nevill, of the Surrey Archæological Society. The restoration of 1840 was one of blunders, and the destruction about ten years later of the ancient sanctus bell, which used to hang under a little canopy outside the spire at the south-east angle of its base, was worse, and whatever the authorities were about to allow this I cannot conceive. The work of 1879 was largely the undoing of that of 1840, and a rebuilding still larger of the north and south aisles, with an extension of the north transept. In carrying out this work, the old Saxon arch at the eastern end of the nave was removed, and the new Early English arch, now to be seen, was inserted. The old Norman arch on the east side of the tower was also altered, being raised several feet, and the question arises, could not the Saxon arch have been dealt with in a similar manner?

In 1840 the sounding-board of the pulpit was done away with, but part of the canopy has been replaced in the north aisle of the chancel. In 1879 also disappeared a beautiful piece of carving—a canopied head supported by caryatides—which had been used as the pulpit door since 1840, and possibly before these alterations had formed the support to the sounding-board.

There are one or two monuments of interest. In the south-east corner of the south chancel chapel is a Decorated or Perpendicular altar-tomb, but this bears neither heraldry nor inscription. This is most probably that of John Westbrooke (d. 1503 or 1513) and Elizabeth his wife, mentioned by Manning and Bray, but in that case it has been removed from the other side of the chapel. In the wall above are four recesses, one of which shows traces of a broken piscina. On the floor of the chancel are three or four brasses. One of these, a small figure of a man in plate-armour, commemorates John Barker (d. 1595). Another is a man in civilian costume, with a woman in the "kennel" head-dress that was common in the first half of the sixteenth century. This is to Thomas Purvoche (d. 1509) and his wife Johanna. The brass inscriptions are worthy of attention—Mary Elliott (Barker) (d. 1600). Walter Underhill (d. 1679), "citizen and fishmonger of London"; and one with a coat of arms in memory of John Warner (d. 1757), formerly rector of Peper Harrow.

The registers date from January 8, 1540, but the earliest portion is lost. The first baptismal entry is 1582; marriage, May 5, 1583; burial 1583. On March 28, 1614, this entry appears, "Was buried ould Gooddy Peto, the widdo of J. Peto." In 1666, the year of the great plague, about thirty-four people are entered as dying of the plague; some are said to be "burried in ye garden." Commencing with Ulmer and including the present one, there have been forty-eight vicars. The mural painting is supposed to represent St. John the Baptist.

In a field about a mile to the south-west from the town, and near the hamlet of Tuesley, which was called the "minster" field, but locally known as the stone pits, was discovered about thirty years ago the foundations of a small church and also some skeletons. A cross set up in the field now marks the spot. This undoubtedly was the Saxon church, and Mr. Welman in his able monograph goes into full details, giving an extract from the register of St. Osmund relating to a visitation made to Godalming by Dean Wanda in 1220 as his authority.

I only intend to mention a few of the vicars of Godalming Church. The first that there is any mention of is Ulmer, a Saxon, in the time of Edward the Confessor. He was followed by Ranulf Flambard, the first Norman vicar, and from all accounts he was a very famous man, and must have been possessed of remarkable vigour and ability. Nicholas Andrews, D.D., instituted 1635, ejected 1643. This vicar came in severe collision with his parishioners, who petitioned Parliament against being compelled to bear with him any longer. They accused him of "being a haunter and frequenter of tiplings in innes and tavernes, and useth gamcinge (whatever that is) both at cards and table, as well uppon the Lord's dayes as others." And finally John Morgan and John Tichborne alleged "that the said vicar and Mr. Wayferar, parson of Compton, roade to Southampton [in another account it is Portsmouth, which is the more likely place], to eate fishe and to make merrie togeather, and there (dyverse tymes) drank healthes to the Pope, calling him that honest olde man." These are only two counts in the indictment; there were several others.

The next vicar was cited before the Parliamentary Committee on March 10, 1645, to show cause "why he pay not

Digitized by Google

ye ffift part of tithe to the wife of Dr. Andrews," and again cited on May 7 following.

After the restoration of Charles II. was the Reverend Samuel Speed; he was grandson of John Speed, who made the maps. He was chaplain of the fleet under the Earl of Ossory, and present at some engagements with the Dutch. He is said to have shown great courage, and Sir John Birkenhead immortalised him in a ballad on the fight:—

"His chaplain he plyed his wonted work,
He prayed like a Christian, and fought like a Turk,
Crying now for the King, and the Duke of York,
With a thump, a thump, thump!"

He was instituted in 1662; died January 22, 1681-2.

The last one to be mentioned, Owen Manning, B.D., instituted December 22, 1763, died September 9, 1801. He was the originator and part author of the history of this county, which was finished at Shere by William Bray. At the age of seventy-five he became blind from his studies and lived for five more years. There is a curious story that he was nearly buried when he was a boy; he had had the small-pox and was actually laid out for dead. His father went in to see him; he raised him in his arms, saying, "I will give my dear boy another chance," and was astonished to see returning signs of life. He desired that no monument should be raised to his memory, but his friends could not be content to comply with his wish, and as you have seen this afternoon, there is a tablet of white marble in the north chapel, enumerating his virtues.

Wyatt's Almshouses.—These are situated at Meadrow, about half a mile on the road to Guildford from the East Bridge, or Bishop's Bridge; they were erected and endowed under the will of Mr. Richard Wyatt, dated 1618, upon part of the Pris marsh. They afford a comfortable asylum for ten poor men, each of whom has two rooms, and is allowed a small weekly sum in addition to certain annual gratuities. The building is a plain one of brick, with the chapel in the centre, and it has a large garden at the back. Miss Jekyll,

WYATT'S ALMSHOUSES, FARNCOMBE.

in her very instructive work called "Old West Surrey," says, "The excellent architecture of the early seventeenth century is well shown by Wyatt's almshouses." With regard to the chapel, I was told by one of the inmates that the present ceiling hid some very fine oak beams, and that there was a talk of its being removed to show these timbers, and I hope this will soon be carried out. The yearly income of the charity, derived from 146 acres, 2 roods, 28 perches of land and 691*l.* vested in Consols, amounts to 182*l.*, and its management is vested in the master and wardens of the Carpenters' Company, as originally stipulated by the founder.

You will recollect, gentlemen, that we visited this Company, under the able guidance of Mr. F. Higgs, on March 20 this year.

The inscription over the entrance stands as he made it:—

"This Oyspitall was given by Mr. Richard Wyatt, of London, Esq., for tenn poore men wth sueficient lands to it for yier mayntenance for ever, 1622."

By the courtesy of Mr. Freeman, clerk to the Carpenters' Company, I have been allowed to see a book written by E. B. Jupp, Esq., F.S.A., clerk of the Company, entitled "Genealogical Memoranda Relating to Richard Wyatt, &c." The will of Richard Wyatt is given in full; and in relation to the almshouses, after several bequests, goes on to say:—"Item, my will is that my executors shall gett Lycence to builde Tenne Almshouses for Tenne poore to dwell in to be sett vp in some convenient place neare Godallmine vpon some pte of Prismarch ffor the buildings of them with a convenient place to saye prayers in every daie I give ffive hundred pounds.—And my will is that none of these tenne soe to be placed shalbe eyther drunkard, swearer, or blasphemer of God, but shall observe such orders as shalbe appointed by the orderers of the Hospitall, or else put out."

The respect in which Wyatt was held by his brethren is evidenced by his filling the office of Master of the Carpenters' Company no less than three times, viz. in 1604, 1605, 1616.

In the same work are numerous examples of Merchants' Marks, some of them being very quaint. After seeing these, and also those marks on the pillar in the church, I am more inclined to the opinion that they are mason or trade marks.

In conclusion, allow me to thank you for the kind attention and the patient manner you have listened to this history of Godalming. My authorities have been:—Reports of the Surrey Archæological Society, especially that of Mr. Ralph Nevill, on the Corporation; "Names and their Histories," by Canon Isaac Taylor, 1896; "Bygone Surrey," by Clinch, 1895; "Highways and Byways of Surrey," by Cecil Parker; "The Homeland Series," by Prescott Row; Manning and Bray's "Surrey," 1804-14; "Church of Godalming," by S. Welman; "Picturesque Surrey," by Moule and Thompson; "Old West Surrey," by Miss Gertrude Jekyll; and I am indebted to Mr. J. H. Freeman, clerk of the Carpenters' Company; to the secretary of the S.A. Society (Mr. J. J. Jenkinson); to Mr. Prescott Row; also to Mr. Harradence and Mr. Potter for their kind assistance; to the town clerk (Mr. T. P. Whately), and to the general purposes committee for their kindness in allowing us to inspect the various documents, &c.; and to the vergers of the church for the assistance they have afforded me; and to the Mayor (Mr. S. Babington), for the valuable assistance and kindly interest he has shown to us this afternoon.

ELEMENTARY SCHOOL PLANNING.

MR. REGINALD G KIRKBY, A.R.I.B.A., F.S.I., city architect, Bradford, read a paper on the above subject before the Engineering and Architectural Sections of the Health Congress at Leeds last week. In the course of it he said the vitally important question of school planning is entering upon a new era. This is due to a growing dissatisfaction with existing models, and an increasing recognition of the need for housing children under better conditions during their school life.

For some years past architects have offered to authorities practically only one type of school—viz., the central hall type, with a series of class-rooms arranged round two or more sides of a central assembly hall. The calling for the submission of competitive designs from architects has doubtless been greatly responsible for the adoption of this type, to the exclusion of buildings of a more suitable character.

Whatever be the reason, it must be admitted that, in contrast with the originality and excellence of modern English architecture generally, school planning has tended to become so stereotyped that we find only one type of school building erected, in town and country alike, on the hillside and the plain indiscriminately, with little regard either to local conditions or educational requirements.

The advantages which may have been claimed for existing models are quite outweighed when consideration is given to the question of the children's health, and to the unsuitability of the buildings in relation to modern teaching methods and hygienic science.

The growing desire for healthier and better adapted schools has led, in a few instances, to the adoption and development of improved types of buildings, and noticeably so where city and county authorities have had the opportunity of consultation and investigation with their own official architects.

Plans of schools recently erected or in progress in Staffordshire and Derbyshire, and at Letchworth and Bradford, are illustrations of these newer types. In these improved schools a detached assembly hall is provided, adequate to meet the growing need for physical instruction, and the class-rooms

Digitized by Google

are so arranged as to enable them to be from time to time flushed or scoured with fresh air, as well as at all times to be provided with cross-ventilation. In such schools children can be taught to love fresh air as nature intended they should, instead of their being compelled to sit in rooms with closed doors and windows, breathing impure air, many times fouled.

The provision of facilities for bathing in connection with these newer schools is a noticeable and welcome feature. Cleanliness should become a national virtue, and this can best be inculcated through the medium of school baths. Ideas of cleanliness learnt at school will be carried into the homes, and must have a far-reaching effect upon the rising generation.

Spray baths would appear to be the best type, with an occasional douche and slipper bath.

The regrettable amount of physical deterioration which is admitted to exist makes it highly desirable, if not even imperative, that open-air schools should be more extensively adopted, and the great benefits already derived from experimental open-air schools warrant their wider adoption. Far better that debilitated children should, through open-air schools, be given a chance to live and grow and develop, than that through inattention they should be allowed to drift into schools for the mentally defective, or otherwise become a burden to the ratepayers, possibly for life.

Open-air schools should provide resting sheds, class-rooms, teaching verandahs, baths and dining hall, with well-equipped kitchen quarters and other offices. A new school of this type just erected at Bradford will accommodate 120 scholars.

In a reflex way the principles embodied in the construction and working of open-air schools are tending to revolutionise school planning generally. Hitherto, school sites have often been selected without due thought being given to any consideration other than the cheapness or otherwise of the land.

Land which costs little in money, it should be remembered, is not always cheap. In future the suitability of the site for the purpose to which it is to be applied will become more and more a determining consideration.

Then in regard to construction, the floor area of class-rooms should be graded to suit the scholars. To assume that what is suited to a child of six is equally suitable for one of twelve is an absurdity. In any case a class-room should not be arranged to accommodate more than forty. This should be a class limit.

A large, single window, without heavy mullions, and almost the full width of the class-room, gives the best light.

If more fresh air be introduced naturally, a larger heating surface will be required to warm the room. But it will be found that children get used to the fresh air, and do not feel the cold so much if a plentiful supply is maintained.

Schools of the type illustrated practically ventilate themselves, and by their adoption some 30*s.* to 2*l.* per scholar is to be saved on the central hall type, the latter requiring necessarily some mechanical means of ventilation to maintain anything like a reasonable standard of atmospheric purity.

It should also be borne in mind that cloak-rooms should be numerous rather than large; that they should be well lighted and ventilated, top-lighting being preferable, and that they should be effectively heated in cold and wet weather. The usual 6 inches space per scholar is too small an allowance, especially in the girls' school.

All new efforts in school planning should embody provisions to meet the varied requirements under the recent Acts instituting medical inspection in schools and the feeding of necessitous children.

Whilst these principles of school planning will be expanded as they become more assimilated, yet education authorities should not hesitate in adopting them, notwithstanding the fact that in some cases a somewhat larger initial outlay may be necessary. Where this is the case, however, it will soon be realised that the compensating advantages to teachers, and the increased physical and educational attainments of the scholars, will far outweigh the other and merely temporary consideration.

The justification in the adoption of such principles will not be confined to architects and authorities alone, but is sure to meet the approval of the nation at large. For what can be more supreme folly than to neglect the units of the race in the earlier stages of their development, only to be burdened with them at a later stage in life as physically stunted and mentally dwarfed inmates of asylums, hospitals, prisons or workhouses?

PATENT OFFICE PRACTICE.*

IN choosing, as a subject for a paper to be read to this Institute, the practice established in the first year of the new Act, I had two objects in view. For a long time past I have felt that the means of making known the decisions on points of practice that arise from proceedings in the Patent Office are very inadequate. As a rule none of the decisions of the Comptroller are published (though a change has been made in this respect by the publication of his decisions as to revocation for non-working), and each year only one or two decisions of the law-officers appear in the Patent Reports. At the same time there are a very large number of decisions continually being given on points of practice and procedure which it would be very useful for those having to deal with patents to know. In choosing this subject I hoped, firstly, to be able to bring before the Institute in a collected form a number of such decisions, and I hoped even more that the discussion that would ensue would bring out and put on record a large amount of information which would not otherwise be available.

But when I attempted to actually collect this information, which I hoped to give to you, I found that the number of points which had been actually decided was surprisingly small. Nothing whatever had been published, and but for the kindness of the Comptroller I should have had to abandon this paper owing to lack of materials. Even the information that he has been able to give leaves so many points uncovered that I should not have troubled you to-night but for my second object—namely, to provoke a discussion in which I am sure much valuable information can be collected.

The results of the first year of course do not include anything dealing with the question of revocation for non-working, supposed to be by far the most important change introduced by the Act, and the rules made on this point do not, I think, call for comment. There will soon be a plentiful crop of decisions on this point, and it is well to leave the question for the present.

Another important effect of the Act has been that only patent agents having a real place of business are recognised at the Patent Office; but I will deal no further with this than by saying that the Office have sought to give full effect to this provision.

Practically the only points I shall attempt to deal with are those relating to patents of addition, patents for cognate inventions, and what has been called the "belated opposition clause."

There were in the first year about six hundred applications for patents of addition, and there is no doubt that this is a very popular innovation. So far there are no published decisions as to what is included in "an improvement in or modification of the original invention;" but this question must shortly come up. Various questions in relation to these patents have, however, been decided, and firstly the practice established is that the application must, in the case where the original patent has been granted and assigned, be made by the assignees of the patent, and that the reference to "applicants" in Section 19 only means that, where the original patent has not been granted, the applicants for such patent may apply for a patent of addition, and not that where the patent has been granted and assigned either the assignees or the applicants may apply. It has further been decided that the whole of the applicants or patentees, as the case may be, must be parties to any application for a patent of addition, but other persons may be joined in the application. This is an exceedingly convenient rule. For example, if one workman of a company makes an invention for which he takes out a patent and assigns it to the company, and then another workman makes an improvement, the company would be able to join the second workman in their application for a patent of addition, and such workman would then, of course, make the declaration as to being the inventor. It has further been held that an ordinary application for a patent can be amended so as to make it an application for a patent of addition at any time up to the grant, even where a complete specification has been accepted and published, and this applies also to patents which were applied for before the Act came into force.

With regard to patents for cognate inventions there are still many points which are either undecided or as to which I have been unable to get information. In the first year between one and two hundred applications were made to put in a single complete specification on several provisional specifications, but so far only a few have been published. The Patent Office, I believe, are adopting a liberal construction as to what is meant by cognate inventions and allow practically the same liberty in joining different provisionals in one complete specification as they would had the same matters been contained in one provisional specification, and there seems little doubt that this was the intention of the Act. I have been unable to hear of any decision as to whether, where a complete specification has been put in and a further provisional subsequently filed, an amendment would be allowed by which the matters contained in such further provisional were incorporated in the first complete

* A paper read before the Society of Architects, entitled "Some points in Patent Office practice arising out of the first year's working of the new Act," by H. Fletcher Moulton, Associate.

Digitized by Google

specification. Nor have I been able to find out whether, where, under Section 6, Subsection 3, the Comptroller has required a part of the complete specification to proceed and a further part to be taken out and treated as a separate provisional specification on the ground of disconformity, the applicant will then be allowed to join the two in one complete specification, of course distinguishing the parts depending on the two provisionals.

In complete specifications which I have seen there is no attempt made to ear-mark the claims that refer to matters contained in the various provisionals. When an action comes to be fought on any of these patents there is no doubt that some very complicated questions will arise, since in deciding on questions of novelty it will be necessary to see, in regard to the different claims, to which provisional they must be referred, in order to decide on the date at which novelty must be established.

I think it may be well to develop this question a little more fully, though possibly it does not come within the title of this paper. Up to the present there was no doubt as to the date at which novelty of the invention claimed had to be established. If the invention was novel at the date of the application, that was all which needed to be proved. But where a series of provisionals dealing with improvements, say, in a particular machine, have been put in and claims have been made, whose wording very probably differs from anything described in the provisionals, it may be necessary to consider in which of these provisionals the invention claimed in each particular claim first appears, and whether it possessed novelty at the date of such provisional. There will probably be a further question as to how far the invention, even if not described in the first provisional, can be said to be a fair development of the invention there described. In fact, whether the patentee can say that it was merely as a measure of precaution that he put in a further provisional specification, and that for the purposes of determining the question of novelty the date of the earlier specification should be taken. This question is likely to be of importance because publications are very apt to occur during the development of an invention. The inventor is often unconscious of disconformity and may only put in the later provisionals on taking professional advice. These considerations make it extremely important even where a second provisional is put in to make the invention therein described appear, as far as possible, a development of that described in the earlier provisional specification.

With regard to the "belated opposition" section there were a dozen case of applications for revocation under these new powers. But there seems little to say about these, as they resemble ordinary opposition cases. It should, however, be noted that it has been decided that there can be no application made to revoke a patent before it is granted, and that if the time for opposition has elapsed the opponent must wait until after the grant before applying to revoke. It has also been decided that where there has been an unsuccessful opposition the opponent cannot apply under this section to revoke a patent, and if he has let the time for appealing against the decision pass, his only course is to apply for special leave to appeal.

Rule 51 introduces an entirely new question for the consideration of applicants and their professional advisers, that is to say, whether the patent to be applied for shall be a grant in the ordinary form or a joint grant for all purposes—*i.e.*, one in which the death of one of the patentees terminates not only his legal interest in the patent, but also his beneficial interest. It seems doubtful whether many applicants will care to avail themselves of a patent of this kind, and more probably any deviation from the ordinary results will be effected by agreement as heretofore.

THE CONCRETE INSTITUTE'S FIRST ANNIVERSARY.

THE Concrete Institute, of which the Earl of Plymouth, C.B., is president, and which has now over 750 members, celebrated its first anniversary on Thursday, July 22, by a visit to the largest Portland cement works in Europe, i.e., the Swanscombe branch of the works of the Associated Portland Cement Manufacturers, Ltd., near Gravesend, better known as the J. B. White Bros.' branch.

About 100 members of the Institute attended this visit, and among the party were Mr. Edwin O. Sachs, F.R.S.Ed. (chairman), Mr. E. P. Wells, J.P. (hon. treasurer), Mr. C. H. Colson, M.Inst.C.E. (Admiralty), Mr. W. T. Hatch, M.Inst.C.E. (Metropolitan Asylums Board), Mr. W. G. Kirkaldy, Assoc.M.Inst.C.E., and Mr. George Corderoy, F.S.I. The visitors were met at Cannon Street station at 10.30 A.M. by the Chairman of the Associated Portland Cement Manufacturers, Ltd. (Mr. F. A. White), and by Mr. H. H. D. Anderson, Mr. Herbert Brooks, J.P., Mr. H. K. G. Bamber, F.C.S., Mr. Alfred Stevens and other directors, and were taken in saloon carriages to Northfleet, where they were entertained to luncheon at the Factory Club. They were then driven by special trams to the Swanscombe works, which contain the largest installation of rotary kilns in this hemisphere. The output by this plant alone exceeds 600,000 tons per annum. The visitors went over the works in eight groups, each group being under a technical guide and a director of the company, and so a most thorough and instructive inspection was insured. Afterwards the visitors were entertained to tea, and they reached London again by 7 P.M.

Mr. White, in welcoming the party, dwelt on the rapid development of the Concrete Institute into one of the most important institutions.

Mr. Sachs in his reply commented on the broadminded policy of the company in including in their invitation such members of the Institute as happen to be directors or chemists to competing cement works. This policy, he pointed out, made for a greater efficiency in the whole of the nation's Portland cement output, a factor of importance in such a great industry as that of the Portland cement trade. Mr. Sachs also remarked on the danger resultant from the keen competition in the selling price of Portland cement, as the building owner really buys the material almost at cost price (few indeed of the cement makers paying anything more than an interest on their preference capital, if as much as that). The rivalry of cheapness allows large manufacturers to keep up their quality, but makes it extremely difficult for the small manufacturer to follow suit. As a matter of fact, he considered the price of Portland cement unnecessarily cheap. There was no reason why the price should not be a little higher, for 1*s.* per ton made but an infinitesimal difference in the cost of a 25,000*l.* building.

Others who spoke on the occasion were Mr. Bamber, Mr. Colson, and Mr. Munro.

GAS HEATING RESEARCH.*

(*Concluded from last week.*)

FROM general observations of the thermopile readings obtained to the end of experiment 11, it appeared as if more energy were radiated above the stove than below it. It was thought that this must be wrong, as by inspection the under surface of the fuel appeared hotter than the top. For this reason there was every justification for raising the equatorial line and the radiometer so that their centres were in a horizontal line with the centre of the stove. Although this, obviously, would make very little difference to the total energy found as radiated, it would considerably alter that found as being radiated above the floor level. In experiments 13 and 14, the effect on the radiation of increased ventilation up the flue caused by putting the fan at full speed, was tried. About 1,900 cubic feet of air passed through the top of the stove per hour, but no appreciable difference in the amount of energy radiated occurred.

In experiments 15 to 20, the fan was turned off completely, and the size of the stop slightly varied. Ventilation was reduced to about 500 cubic feet per hour, but no difference of note in radiation was brought about by decreasing the draught up the flue. From this it is concluded that radiation is not influenced by changes of draught up the flue. This is because the volume of air pressing up the flue did not come into contact with the radiating surface, but passed in at the top of the stove. It is reasonable to conclude then that, under the conditions of these experiments, the amount of energy radiated from the stove lay between 30 and 33 per cent. of the total energy generated by the stove. Of this, about 25 per cent. was radiated above the floor level. In experiment 21, a reflector was placed at the foot of the stove, and the amount of energy radiated above floor level was increased to 28.6 per cent.

It is interesting and extremely suggestive to note what happened during the process of combustion. The gas mixed with air left the Bunsens, and was lighted. At first the flame was comparatively short, and heated the inner surface of the fluel. As this became hotter, the flame lengthened until it reached the top of the fuel, the edge of the outer cone of the flame playing on the inner surface of the fuel. The fire-clay began to radiate in all directions. The radiations from the back of the fuel were sent out into the room,

* Extract from report of the Gas Heating Research Committee appointed by the Institution of Gas Engineers in conjunction with the University of Leeds, and consisting of Messrs. John Bond, J. H. Brearley, and Charles Wood, in co-operation with Professors Arthur Smithells (Chairman), William A. Bone, and Julius B. Cohen, of the University of Leeds, and Mr. E. W. Smith (Research Chemist), to the Institution of Gas Engineers, at their Annual Meeting held in London during June, 1909.

Digitized by Google

except those that were intercepted by the front of the fuel. These were not altogether lost to the room, but were re-radiated to the back surface of the stove, raising its temperature and consequently its radiating power. The bulkier parts of the front of the fuel did, however, affect the radiations sent into the room, as is seen on examining the thermopile readings taken over the whole surface of the stove.

These parts are generally found on the left-hand side of each piece of fuel, and it is worthy of note that in all experiments the readings at 20° and 40° to the left of the stove were a little lower than those 20° and 40° to the right. This would seem to indicate that either the front of the fuel should be much thinner in order that it might attain a higher temperature, and therefore emit more radiations, or that it should be made more open and the back of the fuel more compact so that more direct radiations would be sent into the room. The temperature of the products of combustion, on leaving the stove, varied with the volume of air passing through the stove-flue. Should the house flue be closed except for the stove-pipe, the suction on the stove-flue will be very great, and the flue loss of heat correspondingly high. Should, however, the house-flue be open and the stove-flue about four feet in length, with its entrance restricted there will be a smaller volume of air passing through the stove-flue, but an increased ventilation up the house-flue.

Experimenters have often tried the effect of preheating the air that is used in the combustion of the gas, but so far as is known, no one has seriously tried the effect of also preheating the gas before mixing with the air. There is no reason why it should not enter the Bunsens at the temperature of the escaping products of combustion (90 to 100° C.). A certain proportion of the heat will always be required for the purpose of carrying away the waste gases, but 3,000 B.Th.U. per hour is excessive. There is ample scope here for further experimental work.

Determinations were made of the amount of heat passing directly up the flue and lost to the room. It will be seen by referring to Columns B, F, and K that this was proportional to the volume of air passing up the flue.

B.	F.	K.
Fan off . . .	19 per cent.	500 cubic feet of air
Fan half on . .	30 ,,	1,500 ,, ,,
Fan full on . .	42 ,,	1,900 ,, ,,

About 40 per cent. of the heat generated by this type of stove was heat of convection and conduction—viz., that neither radiated nor passing up the flue. This, as well as the radiated energy, was available for heating the room. The energy radiated into the room struck the walls and furniture in the room, and was converted into molecular energy. The air was warmed by contact with the warm walls, &c., and by passing over the stove. The air of the room was heated very little by the radiations passing through it, but very much by its passing over the objects in the room which had been heated by radiated energy. In this way radiant energy became convected heat. This quantity increased with the volume of air passing through the room.

The temperature of the air passing through the room rose as the volume of air decreased. The volume and temperature being known, a simple calculation gives the volume of air that might be heated from 45° F. to 60° F.

Vitiation of the Atmosphere by Means of Carbon Dioxide from the Stove.—Whenever the volume of air passing up the flue fell below about 1,000 cubic feet per hour, the amount of carbon dioxide escaping into the room increased considerably, whereas above 1,300 cubic feet the escape was only very slight indeed experiments (1 to 14). In no case, even in the small room used, and with the abnormally low ventilation as existed in experiments 15 to 18, was the amount of carbon dioxide greater than 6.2 parts per 10,000. Carbon monoxide was very carefully looked for. Blank tests were made with the outer air, and slight discolorations of the chloroform occurred. In no case did the room air show a deeper colour than the blank, and only when ventilation up the flue had been very much restricted, as in experiments 15 to 18, was any found in the flue gases.

As the ventilation experiments were always run over night, and lasted from 15 to 20 hours, it was ensured that conditions had become constant. During the whole time samples of (1) the room gases, (2) the flue gases, and (3) the coal gas burnt were being collected for analysis. The room was never entered during the experiment, and all temperature and hygrometer readings were taken from outside. At the end of the experiments the manipulator entered the room by means of the double door, letting in as little cold air as possible. In this way the "smell test" could be determined. Only in experiments 15 to 18 was the smell and heaviness of the room air unpleasant. This might be due to (1) the percentage humidity being low, (2) to the high temperature, and (3) to the presence of carbon dioxide.

The percentage humidity of the room decreased with the rise in temperature (experiments 15 to 17), although the percentage increase in the weight of water vapour present per cubic foot of air was higher. This was to be expected. It was stated in the report of the Smoke Abatement Society's research (1906) that a humidity of 58 to 72 per cent. at 15° C. is agreeable. The average room temperature in these experiments was abnormally high, being 25° C. At 15° C. the percentage humidity would increase to within this agreeable limit. If the radiating efficiency of the stove were increased, the amount of convected and conducted heat would be less, and although less heat would go to raising the temperature of the air of the room, more would go directly to warming the walls and objects about the room. This would mean that the "drying" effect would not be so great.

The radiating efficiency of the so-called gas radiators, having open fires, was determined (experiments 22 and 23). In the case of the large type of condensing stove (22), they radiate about 25 per cent. of their heat, and with the smaller type 22 per cent. This could be increased by doing away with the ironwork in front of the radiating surface.

Summarising it has been found that:—

1.—The total radiation from an open gas-fire is about 32 per cent., and this is unaffected by the amount of ventilation through the room.

2.—No carbon monoxide escapes under ordinary conditions into the room, and very little is ever found in the flue.

3.—About 30 per cent. of the heat generated in the stove passes directly into the flue. This figure varies with the volume of air passing through the stove flue.

4.—There is no necessity for products of combustion to enter the room and cause discomfort.

5.—Reflectors may be usefully employed to produce a sensible increase of radiation into the region where it is most wanted.

ART EXHIBITIONS.

WHEN the organisers of the New Gallery adopted this year the unusual practice of dividing their summer exhibition into two sections they reversed the order that was to be expected, for they arranged a better show in the second than they did in the first. Perhaps this reversal was a little unwise, as visitors might be expected to form their judgment from what was shown at the first, as to whether the second exhibition would be of sufficient importance to call for inspection. Whether the rather commonplace character of the first section which was opened in April made a bad impression or not it would not be easy to say, but the fact remains that when a few days ago we went round the three fine rooms in Regent Street we were almost in undisturbed enjoyment of the many excellent pictures on the walls. There are certainly at present a very large number of counter-attractions for the lover of contemporary, modern and ancient art, and it may have happened that on that particular occasion the rival shows chanced to be in the ascendency. There can be but few dilettanti who have enough enthusiasm to visit every exhibition in London that is pronounced to be worth seeing. Such a verdict can unhesitatingly be pronounced as to the latest portion of the twenty-second summer exhibition at the New Gallery which closes on August 14. It is true that some of its more conspicuous works have been seen elsewhere, for it was agreed that whereas the first portion should consist entirely of works not previously exhibited in London, the exhibitors reserved to their discretion the right to make the second more or less retrospective.

The visitor would be hard to please who was not charmed by the group of pictures Nos. 17 to 27 in the South Room, each by a different artist. If he is most attracted by landscapes there is "Barrow Down, Dorset," by Mr. H. Hughes Stanton, a bold rendering of a large space with majestic clouds; for the fanciful mind there are three pictures of sea maidens, the one by Mr. E. Reginald Frampton is entitled "A Pearl," showing the oyster home of the sea goddess. Of another character altogether is "The Return from the Pageant," by Mr. T. C. Gotch, which suggests that the young performers give as much enjoyment in an informal journey back to their homes as in any of the official episodes. The light of the Chinese lanterns is just of the right sort to harmonise with the holiday scene. "A Sleeping Girl" is

Digitized by Google

one of the three charming, though small, contributions to the exhibition by Mr. R. Anning Bell, each of which is prominent for an easy spontaneity and unstudied effect which contrasts with the impression of laboured striving towards the decorative sometimes seen. Near to this group is an Eastern subject by Mr. John Lavery, R.S.A., "Moonlight—House tops, Tangier"; brilliant though such light may be we would expect to see more subtlety and greater play of mysterious shadows among these close-packed houses with walls of brilliant white. In "St. Martin's Summer" Mrs. Swynnerton has revelled in bright colour and daring composition, for that delightful season is typified in a voluptuous winged female.

In the West Room "The Mill Pond," by Mr. Charles Shannon, is as full of masculine vigour as the five bathers who are so prominent in the picture. It should be compared with Mr. Cecil Rea's "Bathers" in the adjoining room. There are two exceptional portraits in this room, viz., "The Velvet Coat," by Sir James Guthrie, P.R.S.A., and "Babs," by Mr. J. J. Shannon, R.A., elect and others by less prominent artists. Mr. Shannon must have wished to emphasise the diminutiveness of the little girl who seems to be bravely combating her uneasiness as she stands in (presumably) her underclothes before a heavy curtain, and is wondering whether it is a game or not. It arouses a feeling of amused pity for the "poor little thing" rather than of admiration for a charming little girl. Sir J. Guthrie has added to a high reputation by "The Velvet Coat"; possibly he was puzzled as to how to produce something striking out of his sitter, and consequently was moved to make a departure from ordinary portraiture. The elderly lady appears to have been stopped momentarily as she rose out of her chair and was leaving the room; the pose is of an arrested motion that will be resumed as soon as some question has been answered. Mr. Herbert Draper no doubt intends at some later time to people his "Land-locked Bay" with sirens and shipwrecks, for the high and precipitous cliffs must assuredly be more accustomed to stormy buffeting than to the lazy ripple of the summer waves as here shown. This atmosphere of unruffled peace contrasts well with the movement in "Fresh Weather in the Channel," by Mr. Julius Olsson, near by.

Mr. W. Lee-Hankey has rendered two very dissimilar subjects in "It's the Child's Turn Now," and "In the Shadow"; the first is an open field with strong light on the dead mother and her little girl, the second is full of uncertainty in the heavy shadows and dim evening light showing the soft mellow tones of an old cottage. "The Incoming Tide," by Mr. R. W. Allan, is typical of fishing boats bringing home their hard-earned catches. In this North Room is a portrait by Mr. John Lavery, "Mary in Green," which, like his "Mrs. Rattagan," will give much pleasure to all who see it. An unmistakable air of distinction belongs to "The Artist's Wife," by Mr. J. Young Hunter, thanks to the pose and dress and figure.

The Central Hall contains as usual sculpture and handicrafts by artists of high reputation and merit.

THE LATE JOHN ARCHIBALD CAMPBELL, F.R.I.B.A.

IN our last issue we announced the death on July 19 of Mr. John Archibald Campbell, senior partner of the firm of Messrs. John A. Campbell & A. D. Hislop, architects, Glasgow. Mr. Campbell served his apprenticeship with the late Mr. John Burnet, and thereafter studied for a number of years in Paris, and travelled on the Continent. When he returned to Scotland he again entered the office of Mr. John Burnet, and in the year 1886 was assumed by Mr. Burnet, with Mr. John James Burnet, as a partner under the firm name of John Burnet, Son & Campbell. The partnership was dissolved in 1897 when Mr. Campbell entered into business on his own behalf. He recently assumed Mr. A. D. Hislop as a partner. Mr. Campbell won the Tite prize of the Royal Institute of British Architects in 1885 and was elected a Fellow in the year 1906. He was a prominent member of the local institute.

Mr. Campbell's work is well known. His most important commissions were perhaps the various important office blocks and insurance buildings designed by him in Glasgow, which all bear evidence of scholarly skill and marked individuality. The following are some of the most recent:—The Edinburgh Life Assurance building, the Northern Insurance Company's building, the Britannic Insurance Company's building, and the West George Street Property Company's building. His domestic work was also very fine, and a large number of important mansion houses have been erected to his designs. He was a regular contributor to the Royal Scottish Academy and the Glasgow Institute of Fine Arts. He was architect for the Queen Victoria School and Memorial Chapel, Dunblane, recently opened by H.M. the King, and at the opening ceremony was presented.

Mr. Campbell was fifty years of age and was unmarried.

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *American Architect* has in its tour of the southern States now reached Birmingham, Alabama, where the magnificent railway station has attracted its attention and occupies the whole number. Both for extent as an engineering problem and for the merit of its architectural design, due to Mr. P. Thornton Marye, this is one of the notable railway stations of the world.

Die Kirche has for its chief subject the new parish church of St. Wolfgang at Munich, of which Hans Schurr is the architect. Designed in the Baroco manner of German eighteenth-century work, this is quite a remarkable work. The plan, starting from the basis of an internal elliptical dome over its central area, with extensions east and west on the major axis, is full of interest and highly effective both within and without. Quite distinct in motif yet striking in effect is the church of St. Paul at Cologne, by Stephan Mattar, architect, a monograph of which is reviewed, with illustrations.

Deutsche Bauzeitung further illustrates the competition for new police buildings at Munich, to which it has already given much attention. It also takes occasion of the International Archæological Congress at Cairo to illustrate some of the buildings of that city, as well as the arena of some of the latest explorations.

Het Huis has an interesting article, with many illustrations, on the seventeenth-century representation on medals of buildings in Amsterdam, Haarlem, Leyden, Dordrecht, and other towns of the Netherlands. There is also a pleasing account of the Flehite Museum at Voorgevel, in which an air of completeness is obtained by the design of the room according with the objects it contains, thus presenting the picture of interiors as they were when their components were produced, a method of treatment quite possible in a small museum and very effective as well as informing. Voorgevel is worth a visit in order to see this museum.

Dekorative Kunst gives us some illustrations of the International Photographic Exhibition at Dresden and of a somewhat curious block of buildings in the Nassauischen Strasse, Berlin, in which, as part and parcel of one design, a church is combined with residential flats, a development of property belonging to the Old Lutheran community of Berlin. No plan is given, but the photographs suggest that the problem has been rather cleverly tackled, and a not inharmonious combination effected of a distinctly ecclesiastical and secular expression in the several parts of the design. An interesting article appears on the students' work at the Art Training School of Zurich.

Stone shows us some remarkable sculptures in Woodbury grey granite by H. A. MacNeil for Cook County Court House, Chicago—seated male figures of "The pioneer spirit of Chicago" and "Lake navigation."

The *Engineering Record* contains a paper on "Concrete Reinforced by Nails," read before the recent convention of the American Society for Testing Materials by Leon S. Moisseiff, which shows to what extent the compressive strength of concrete can be increased. The most striking result was a compressive strength of 17,800 lb. per square inch on a cube fifteen months old.

COMPETITION RESULTS.

MESSRS. BRIGGS, WOLSTENHOLME & ARNOLD THORNLEY, FF.R.I.B.A., architects, North John Street, Liverpool, have been successful in the limited competition for the proposed arts building for the Liverpool University Buildings. Their design, marked "Quadrangle," was selected by Mr. E. Guy Dawber, the assessor, out of the four designs.

The Court of Common Council have adopted a report of the streets committee recommending the removal of the gates enclosing the parish of St. Bartholomew-the-Great, Smithfield, and granting 1,500*l.* to the trustees by way of compensation.

The Council of the Royal Sanitary Institute have accepted the invitation to hold the annual congress at Brighton in 1910.

FORTHCOMING EVENTS.

Saturday, August 7.

Institution of Municipal Engineers: Annual General Meeting at Durham.

Brighton and Hove Archæological Club: Excursion to Wolstonbury.

Monday, August 9.

Architectural Association: Annual Excursion, Headquarters at Cheltenham, August 9 to 14.

Tuesday, August 10.

Sheffield Master Builders: Return Visit from the Belgian Builders August 10 and 11.

Saturday, August 28.

Architectural Association: Camera and Sketching Club, Visit to Croydon and Beddington.

THE BRITISH MUSEUM.

ALTHOUGH the number of visitors has not reached the high-water mark of the attendances in the years 1903 to 1905, that for last year shows a considerable advance beyond its immediate precursor, being 743,413 as against 646,300. The number of students remains practically steady, there being but a fractional decrease from 55,738 to 55,676.

The extension of the buildings at Bloomsbury proceeds very slowly, as no building operations have been undertaken in connection with the new wing in Montague Place with the exception that a contract for building the new boiler-house was entered into during the autumn, and this is still in progress. A commendable piece of work has been the construction of fire-resisting divisional walls in the roof of the western and southern galleries of the Museum, and provision has been made for continuing the work in other sections of the roof. The evil effects of the manner in which Government starves our great national museums is seen in the fact that an iron shed has had to be erected for the accommodation of casts from the antique, recently transferred from the Victoria and Albert Museum. Of course the new wing ought to have been ready for them, but at the rate it is proceeding the iron shed will be worn out before a permanent home is able to accommodate this acquisition.

All departments of the Museum have added to their treasures. The Department of Printed Books has acquired eighty English books printed before the year 1640, and sixty-four Incunabula (books printed before the year 1501). The student of hygiene should be interested in PLUTARCH's "De tuenda bona valetudine precepta Erasmo Roterodamo interprete," printed by RICHARD PYNSON, 1513, and Sir THOMAS ELYOT's work "The Castel of Helth," printed by THOMAS BERTHELET, 1539. Of interest also is the record by Mr. FREDERICK M. FAY, Master of the Merchant Taylor's Company for 1895-6, entitled "A Historical Collection of the Pictures, Herse-cloths and Tapestry at Merchant Taylors' Hall, with a list of the Sculptures and Engravings."

The Department of Manuscripts has been fortunate in receiving by bequest a Latin psalter written throughout in gold and containing a portrait of the Emperor LOTHAIRE (840-55) and two other miniatures, with explanatory verses, and, among other supplementary matter, a prayer composed apparently by a sister of LOTHAIRE, and mentioning him and other members of her family. This manuscript was probably written for this lady or for a religious house in which she was interested; as early as the tenth century it belonged to the abbey of St. Hubert in the Ardennes, and it remained there till the French Revolution. To the upper cover is attached a large silver-gilt medallion containing a crowned head in profile in high relief, perhaps of the ninth century, and on the lower cover is a fine ivory figure of DAVID, of the twelfth century. In the same bequest (by the late Sir THOMAS BROOKE, Bart., of Armitage Bridge, Huddersfield) were included three monastic chartularies, of Cockersand Abbey, county of Lancaster, 1268; of Fountains Abbey, county of York, fifteenth century; and of Selby Abbey, county of York, fourteenth century. Amongst other acquisitions of this department we may specially mention a chartulary of Waltham Abbey, county of Essex, compiled by ROBERT FULLER, the last abbot, 1526-40; Collections relating to Kent, including muster-rolls and inventories of church furniture, 1548-9, early seventeenth century; Monumental inscriptions "in the part of Holland in Lincolnshire," apparently collected by ROBERT TAYLOR, of Heckington, 1790; Drawing in pencil by HENRY DAVY of the north porch of Great Bealings Church, county of Suffolk, 1852; Accompts for building and repairs of the Cathedral of Troyes, including the erection of the great bell-tower, July 1410 to July 1411.

The Department of Prints and Drawings has acquired some interesting drawings of the French and English schools, and has added to its collection several choice specimens of Japanese wood-cuts by HIROSHIGO, HOKUSAI, KIYOMASU, KIYONAGA, KORIUSAI, KUNISADA, and others. We may specially note amongst the additions to the collections of this department forty-six drawings and sketches by PIRANESI of Roman ruins, imaginary classical buildings, &c.; etchings by CHARLES MERYON of "Chenonceaux" and "Chevet de St. Martin-sur-Renelle"; drawings by SAMUEL PROUT of Temple Farm, near Rochester, and Quarry House, at Rochester, these being presented by Mr. R. PHENE SPIERS, F.S.A.; a collection of "Drawings of Old London," by W. C. ALEXANDER.

By the Department of Greek and Roman Antiquities the Account of the British Museum Excavations at Ephesus (1904-5) has been published, and a fourth edition of the Guide to the Sculptures of the Parthenon has been issued. A Guide to the Exhibition of Greek and Roman life and a catalogue of the Roman pottery have also been published. Amongst the acquisitions of this department may be specially mentioned a bronze arm of a couch decoratively treated, of Græco-Roman work, on the upper end of which is a bust of ATHENA, or ROMA, and on the lower end a bust of a woman veiled, perhaps HERA, whilst between them is a figure of DIONYSOS reclining and holding a wine cup. A notable donation by W. C. ALEXANDER, Esq., through the National Art Collections Fund, is a bronze statuette of a negro boy mounted on a high base, which is of the best period of Græco-Roman work. The figure, which is infibulated, is of a strong thin-limbed type; he is nude, and stands with his left foot advanced, right

Digitized by Google

hand on hip, and left hand raised above the head. On the palm of the hand are marks of an attachment, as if it had supported some heavy object, such as a lamp, and the eyes are directed towards the hand. The base is unusually large, circular in shape, and supported on three lions' feet. Both statuette and base have an uncommonly fine smooth grey patina. Other acquisitions of interest by this department are a marble head of a youth of supposed Polycleitan style, of the type of the "Westmacott athlete," Greek work of the fifth century B.C.; and a series of fragments of wall plaster from Rome with various decorative designs painted in colours.

The Department of British and Mediæval Antiquities and Ethnography has not during the past year issued any catalogue, though that of ivory carvings has been prepared for press, and further progress has been made with the Guide to the Ethnographical Gallery. The acquisitions of the department have been numerous, ranging in date from palæolithic implements found in a gravel pit at Kennet, near Newmarket, to a brass snuff-box with bust of Shakespeare and inscription relating to the Commemoration, April 23, 1816. The field covered by this department under the title of ethnography is unlimited; hence the large number of acquisitions. Amongst these we may note in the prehistoric section an ornamented bronze celt with flanges found in the Thames near Medmenham Abbey; a bronze dagger blade with three stout rivets, found at Sproughton, near Ipswich; a small bronze dagger blade, found at Firle, Sussex. An important series of flint and stone implements, and implements, ornaments and pottery of the Bronze and Early Iron Ages, chiefly from Hohenzollern and the Swiss Lakes, has been presented by the Rt. Hon. Sir John Brunner, M.P., and Sir Henry Howorth, K.C.I.E.

In the Romano-British Section there have been raised from a Roman villa discovered in 1908 at Hemsworth, near Wimborne, Dorset, and added to the collection, a tesselated pavement with Venus rising from the sea and dolphins in the border, and other pieces of Roman paving, including squares of tile and Kimmeridge shale so used. A curious acquisition in this section is ten specimens of Gaulish redware dredged from the Pudding Pan Rock, Herne Bay, Kent. In the Anglo-Saxon Section has been acquired a remarkable bronze bowl of early British character, with two of three escutcheons for attaching chains for suspension which, with the bronze and iron mounts of a wooden bucket, an iron spear-head, and other objects, was found at Ewelme, Oxon, on the site of a cemetery. The many other acquisitions of this bric-à-brac department seem to us to be, as a rule, more curious than valuable or instructive.

The Department of Coins and Medals has acquired during the year 5,543 coins and medals, of which 105 are of gold, 1,662 of silver, 3,681 of bronze, and 95 of other metals. The most important acquisition is that of the Leopold Hamburger collection of Greek coins of Phœnicia, Palestine, and neighbouring countries, including a certain number of Roman coins relating to Judæa. The collection comprises 17 gold, 166 silver, and 2,546 bronze coins.

NOTES AND COMMENTS.

Mr. Edwin T. Hall, as chairman of the Estates Governors of Dulwich College, has, in a letter to the daily Press, well shown the futility of the arguments of those who assert that building land is "held up" by its owners or "allowed to waste" by not being at once covered with houses. What is true of the Dulwich College Estate is true elsewhere, and Mr. Hall points out that as there are already 4,670 empty houses in the boroughs of Camberwell and Lambeth, the erection of an additional 3,000, which would involve an outlay of 1,620,000*l*., would, even if these new houses could be sold at a considerable loss, merely result in increasing by thousands the number of unlet houses elsewhere in the boroughs. Thus, according to the Budget proposals, the Dulwich College Estate is to be taxed because its Governors do not, at a serious loss to their trust, bring ruin on many other owners of house property in the boroughs of Camberwell and Lambeth. The idea of taxing landowners because they do not let land on which nobody wants to build seems to us ridiculous in the extreme. Are the ratepayers of London to be taxed because their representatives, the London County Council, cannot let at once the land in Kingsway at a price which experienced valuers say it ought to command? Then, again, Mr. Hall points out that the uncovered land belonging to Dulwich College is fulfilling a very useful service to the community by providing playing fields, the demand for which is greater than the supply. This is true of many parts even of the county of London, as everyone knows who has tried to find a ground for a cricket, tennis or football club. One of the great causes for the lamentable decay of amateur clubs and the increase of professionalism in London is the difficulty of finding a bit of turf on which to play without a long and expensive journey.

With the desirability of a Ministry of Art as distinct from the department of the Board of Education advocated by Mr. J. Fisher, Chairman of the Society of Art Masters, at its annual meeting, we thoroughly agree, not only because it appears that Art Masters have no direct representation on the Consultative Committee of the Board of Education, but because the recognition of art as a matter of public importance goes beyond the question of education, and the regulation of art matters in other directions would afford ample occupation for the most industrious and hard-working member of the Ministry.

Anything that tends to reduce the cost of freight is an advantage to the trade, and hence to the wealth of the country, and therefore the idea of a clearing-house in London for dealing with goods carried over the various railway systems in the metropolis, for which Mr. R. Stephen Ayling, F.R.I.B.A., has prepared plans of a building 400 feet wide by 1,000 feet long, capable of accommodating forty trains of fifty waggons each, is one worthy of consideration. It is estimated that by the provision of such an institution the railway rates could be reduced by 66 per cent., which, if correct, would be of great advantage in assisting British producers to compete more successfully than at present with foreign exporters.

It is good news to hear that the Smithfield Gateway is to be preserved, a contract having been signed for the purchase of the superstructure of the gateway and a portion of the house on its south side, and we hope the rector may soon receive donations of the further 500*l*. odd required to complete the purchase and repair the building internally, so that this interesting relic of old London may be rendered safe.

That the "model dwellings" in huge blocks of several storeys as the solution of the housing problem should be no longer regarded as the best or the only possible is matter of congratulation on every score. That for this system should be substituted the two-storey cottage in the suburbs with a bit of garden must lead to healthier and happier lives for town-workers. The annual meeting of the Improved Industrial Dwellings Company showed that this body, which is run on business lines, recognises the change that increased facilities for locomotion has rendered possible and profitable alike for the Company as for their tenants. It is the bit of garden that is the main factor, for not only does the tenant gain by its produce, but the time spent in working it is recreation, less expensive than any open to the town-dweller in a block of model dwellings with its paved courts.

Ivy may be pretty to look at and so add to the attractiveness of ruins for the ordinary visitor, but the members of the Kent Archæological Society had impressed upon them the destructiveness of the plant when visiting Eynsford Castle, which probably dates back to the time of Henry II. There is some difference of opinion as to whether or not ivy makes a wall damp, and whilst its

Digitized by Google

influence on sound walls with good mortar may be small, there can be no doubt that its growth is extremely prejudicial to old walls whose surface is insufficient to prevent its intrusion into their interior.

The alteration proposed by the Tariff Bill of the United States to prevent imposts on works of art brought into that country is certainly popular with the citizens. That such works if in existence for more than twenty years should be admitted free instead of paying twenty per cent. ad valorem duty, or under the most favoured nation clause fifteen per cent., may be trusted to extend the eagerness with which the patriotic nouveau riche of Chicago will pay high prices for the valuable works of art that still remain in the country houses of England, and so deprive us of some of the treasures that are to some extent national possessions. But the manufacturer of genuine antiques will have a glorious time; old masters whose paint is hardly dry, old furniture with shot-made worm-holes, Egyptian and Buddhist deities made in Birmingham will flood the American market, especially if the price is high—and the dealers may be trusted for that. Why the limit of twenty years' age should be selected it is difficult to conceive. It will not ensure veritable antiques, nor if the standpoint of excellence in art is supposed to be desired will this be safeguarded, for the work of to-day may be as pre-eminent as any that was produced twenty years or more ago. There is a valid argument in favour of the free admission of works of art as art, but none in favour of antiques, which on the one hand are not necessarily good because they are old, and on the other may easily be forgeries.

COMPETITION FOR NEW ARTS BUILDING.

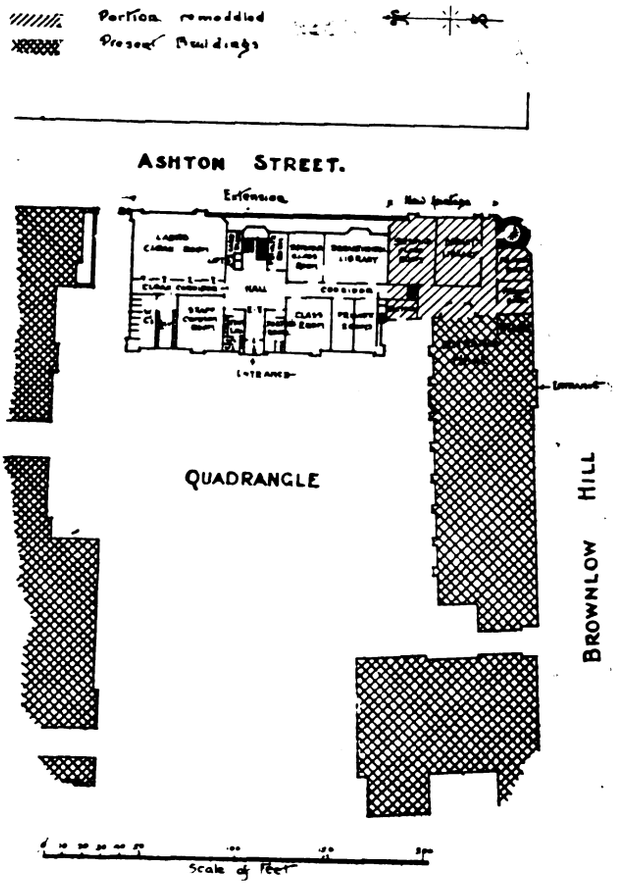
THE UNIVERSITY OF LIVERPOOL.

THE Council of the University invited competitive designs from Messrs. Briggs, Wolstenholme & Thornley, FF.R.I.B.A., Mr. J. F. Doyle, Mr. F. W. Simon, F.R.I.B.A., and Messrs. Willink & Thicknesse, FF.R.I.B.A., all of Liverpool, for an extension to the Victoria Building to house the Faculty of Arts, and appointed Mr. Guy Dawber, F.R.I.B.A., as assessor. The site has frontages to Ashton Street and to the quadrangle, and the competitors were not restricted in any way by ancient lights.

The Council desired that the new building should harmonise in form and colour with the present University, but did not bind the competitors to follow the existing internal or external detail. In their designs the competitors had to arrange their schemes so as to render possible a reconstruction of that part of the present building from the corner of Ashton Street to the junction with the new building for the purpose of providing future head quarters for the University Library, from which the principal departments of the new building will radiate. All the designs are on a similar principle and have a centre corridor with rooms on both sides.

The selected design is that submitted by Messrs. Briggs, Wolstenholme & Thornley, under motto "Quadrangle." The arrangement of each floor being simple and direct, is without waste. As will be seen by the accompanying sketch the entrance is from the quadrangle in the centre of the building and leads into a large entrance hall, with the staircase facing the entrance, and the corridors running right and left. The ladies' cloak rooms and sanitary conveniences are well arranged, being concentrated at one end of the ground floor, and cut off by means of a cloaks corridor, end lighted from the main hall. The corridors generally are lighted by means of borrowed lights. The class rooms are in all cases left-hand lighted. The windows of some of the class rooms to the quadrangle are somewhat small and appear to have been subordinated for architectural effect in elevation. The seating of the lecture room on the second floor is placed parallel with the length of the room, &c., and has the side desks bevelled. The arrangement shown will not be very comfortable for students occupying the side desks.

The elevations are well designed in Late Gothic influenced by a French feeling and will harmonise with the present building. The half-inch details are effective, being strongly drawn and finished in a monotint wash.



The materials proposed to be used in the elevations are grey brick with red sandstone dressings, and the cost has been based upon a cube of 598,400 feet at 10*d*. per foot, 24,950*l*.

In preparing his scheme Mr. F. W. Simon, the author of the design distinguished by a red seal, has evidently been too much influenced by the provision at some future time of a large hall in lieu of the existing arts theatre.

The placing of the entrance, entrance hall and staircase at the junction of the new with the old building conveys a feeling of lack of cohesion which is further emphasised by the dark colouring of the old portion. The corridor has the appearance of being wasteful, the line being broken by pilasters. The elevations and details look well, and are the best part of the scheme. They are treated in a severe classical manner, and are drawn in pencil, washed in with a monotint, and shaded in the modern French method. We do not understand how the style of treatment can be considered to be in keeping with the present building.

In design A, by Messrs. Willink & Thicknesse, the scheme appears to have been sacrificed by placing an entrance archway to the quadrangle in the centre of the building, and thereby disconnecting the ground floor class rooms from the entrance hall. The corridor on each floor is long and narrow and has wasteful recesses. The position of the lift is not good, and would be somewhat unsightly. The lighting of the gents' cloak room (in the basement) does not appear satisfactory, being lighted at one end by pavement lights.

The position of the drawing and map rooms in a Mansard roof would probably be unsatisfactory and lead to shadows being cast by the sides of the dormer windows. The elevations are highly coloured and show a restful building in the Græco-Roman style. Again we fail to see how this class of treatment can be said to be in harmony with the existing building. The half-inch details are carefully pencilled in and laboured in finish. The ultimate result hardly warrants the amount of time which must have been spent on the drawings. A word of appreciation is due to the authors for the sketch perspectives which accompany the scheme.

PLAN OF MESSRS. BRIGGS, WOLSTENHOLME & THORNLEY'S DESIGN.

The design under motto "Arts," by Mr. J. F. Doyle, is marred by the insignificant entrance placed at the end of the building. The ladies' cloak room accommodation is not sufficient, nor is it isolated, and has ranges of w.c.'s on inside walls. The lecture theatres are right-hand lighted, and sufficient thought does not appear to have been given to the lighting and seating of the class rooms in general. The elevations follow the style of the present building.

The scheme appears to have been hurriedly prepared, and the drawings are not so complete as those prepared by the other competitors.

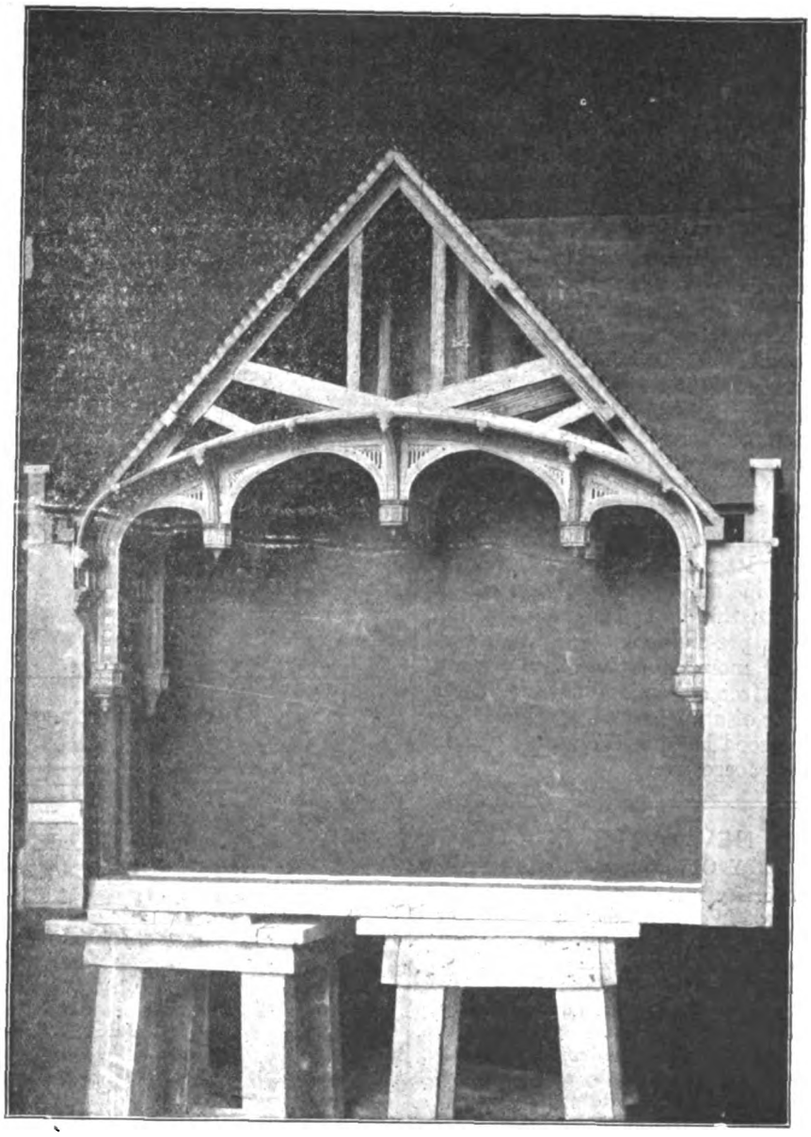

Fig. 1.—MODEL OF CROSBY HALL ROOF.

THE TRADES TRAINING SCHOOLS, LONDON.

THE report of the judges on the work done during the session 1908-1909 at the Trades Training Schools of the Worshipful Companies of Carpenters, Joiners, Painter Stainers, Plaisterers, Tylers and Bricklayers, and Wheelwrights has recently been issued, and affords us an opportunity for a short review of the excellent work that has now been carried on for fifteen years in these schools at Great Titchfield Street, London, during which some 4,000 workmen have had the knowledge of their craft increased by the instruction they have received in the schools.

The first point that should be noted is that these schools are open only to those engaged in the trade for which the classes are held; they are not for amateurs, but for actual craftsmen, apprentices, or improvers, whether carpenters, handrailers, joiners, masons, painters, plumbers, smiths, stone-carvers, modellers from the life, tilers and bricklayers, wheelwrights, wood-carvers, electric wiremen. The schools are maintained at the cost of the Worshipful Companies of the City of London mentioned above, as the moderate fees charged, which appear to be as a rule 5*s*. a term for adults and 3*s*. for apprentices and improvers, cannot be expected to meet all costs.

High quality in the character of the technical instruction given is apparent from the recognition obtained by two of the instructors at the Royal Academy, where both Mr. A. Broadbent, instructor of the classes for modellers, sculptors, and architectural carvers in marble, stone, &c., and Mr. Charles L. Hartwell, S.B.S., instructor of the life class, are exhibitors, the latter having had two of his works purchased under the terms of the Chantrey bequest. The quality of the work produced by the students is evidence that the other instructors are of equal calibre with the two we have mentioned, and by the courtesy of Mr. H. Phillips Fletcher, F.R.I.B.A., the Director of the Schools, we are able to illustrate some of this—a model of the roof of Crosby Hall (Fig. 1), made from measured drawings by Mr. A. C. Goulder, A.R.I.B.A.; a brick font (Fig. 2), some of the work of the modelling, sculpture, and stone-carving class (Fig. 3), and some of the work of the wood-carving class (Fig. 4). One point about the methods of the schools appears to us somewhat questionable. Design is not taught, and with this we agree, as the avowed object of the schools is instruction in operative craftsmanship, but the students are to a large extent allowed to make their own designs for what they execute. No doubt this adds to the interest of the men in their work, and as this is in the nature of overtime or recreation, possibly something must be conceded, but the result is that the students often spend their time on badly designed creations and may possibly be led to think that they can design. It would be a fine ideal for the Trades Training Schools to raise up a class of craftsmen equal in ability to those who worked for Sir

Digitized by Google

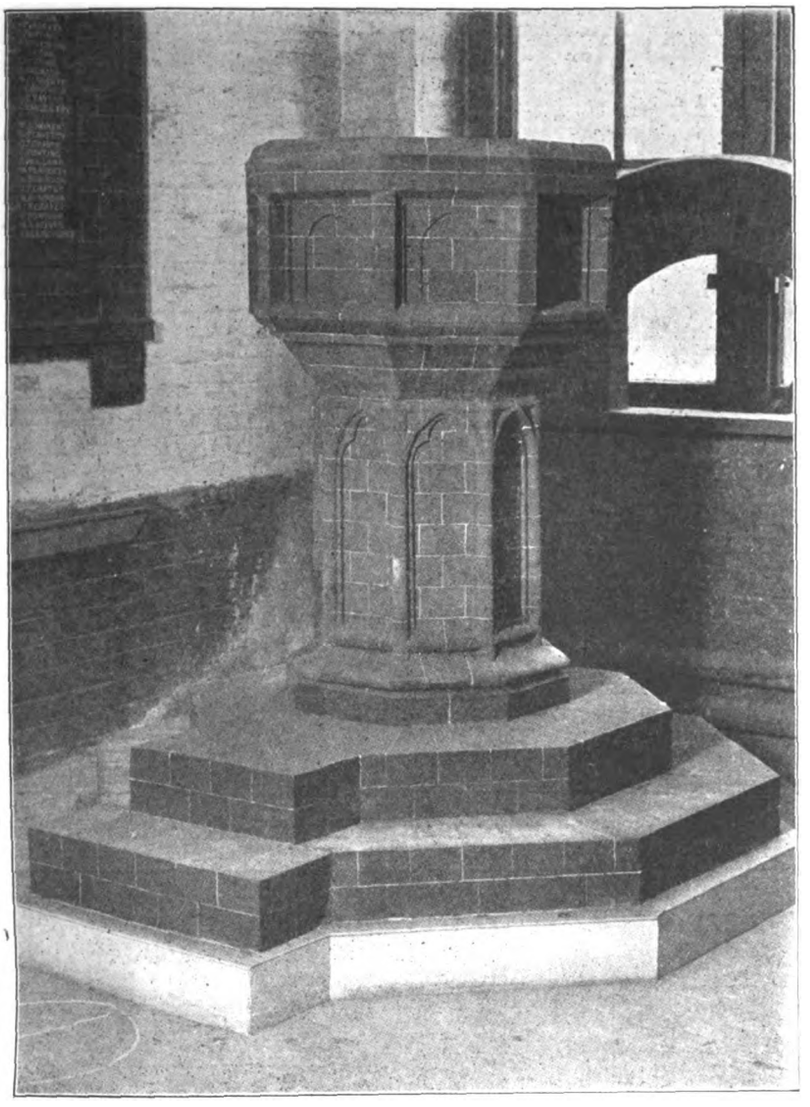

Fig. 2.—A BRICK FONT.

Christopher Wren, but it is an ideal difficult of attainment, and cannot be reached by letting the students do what they like. Thus, when we see bad grammar in design, as in the brick font, we must recognise that the Instructors and the Director of the Schools are in a difficult position.

The list of judges who examine the students' productions contains some well-known names, as Sir William Henry White, K.C.B., Sir Guilford Molesworth, K.C.I.E., Mr. Ernest George, Mr. Walter Cave, Sir George Frampton, R.A., Mr. Seymour Lucas, R.A., Mr. W. Goscombe John, R.A., Mr. Banister F. Fletcher, Mr. A. W. S. Cross, Mr. Mervyn E. Macartney, Professor Elsey Smith, and to show what they think of the work done during the past year we give the following extracts from their report:—

Carpenters.—The work of nineteen students is exhibited and the general standard of craftsmanship seems exceptionally high. The roof of Crosby Hall, by W. H. Gale, has been shown as a model with remarkable success, and has gained the Banister Fletcher medal for the best craftsman in the school, and there are two exhibits of domes, together with a circular bay, showing a good knowledge of geometrical setting out as well as excellent workmanship.

The more straightforward work consists of models of floors, joints, &c., and shows good and accurate preparation and fitting, and the amount of work exhibited by individual students points to serious application throughout the session. The judges are very satisfied with the work of the class as a whole.

Joiners and Handrailing.— The attendances this year have not been so numerous as usual, nor is the number of exhibits so satisfactory. Some of the models submitted, however, are excellent.

The oak pulpit, by R. J. Holley, is a very fine piece of work, entailing considerable skill in setting out and execution.

Handrailing.—There are several good specimens of handrailing in progress, but the judges would be glad to see more exhibits completed.

Masons.—The workmanship shown this year is satisfactory, and although there are not many completed models, the judges are pleased to see that the students are being well grounded in the simpler forms of masonry.

They hope that something a little more ambitious may be attempted in the future, and that the models will be more numerous.

Painters.—A number of very creditable specimens of decorative painting and sign writing have been produced during this session, and the judges consider that the traditional excellence of the class has been well maintained.

Plasterers.—The work executed in this class is a distinct advance on previous years, some of the models showing considerable promise. The judges were especially pleased with the careful examples of piece moulding by G. Davies, in which the actual clay model and moulds were shown.

Plumbers.—The number of exhibits this year, together with the general craftsmanship, is most gratifying, and testifies to the excellent method of instruction given.

Smiths.—The judges regret that more works have not been completed, but consider this due to the ambitious designs attempted. The welding and repoussé work is of a first-rate quality, and reflects great credit upon the class as a whole.

Stone-Carvers.—The judges were very gratified at the great progress made this year, there being considerably more

Digitized by Google

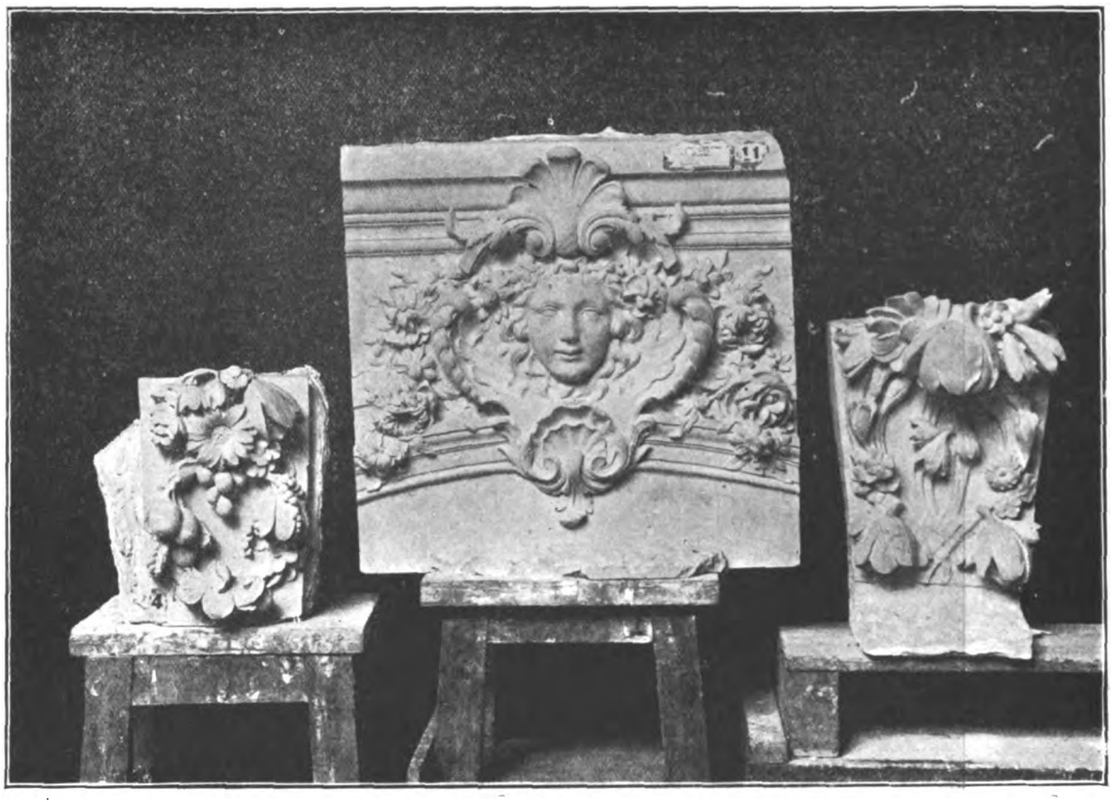

Fig. 3.—SCULPTURE AND STONE CARVING.

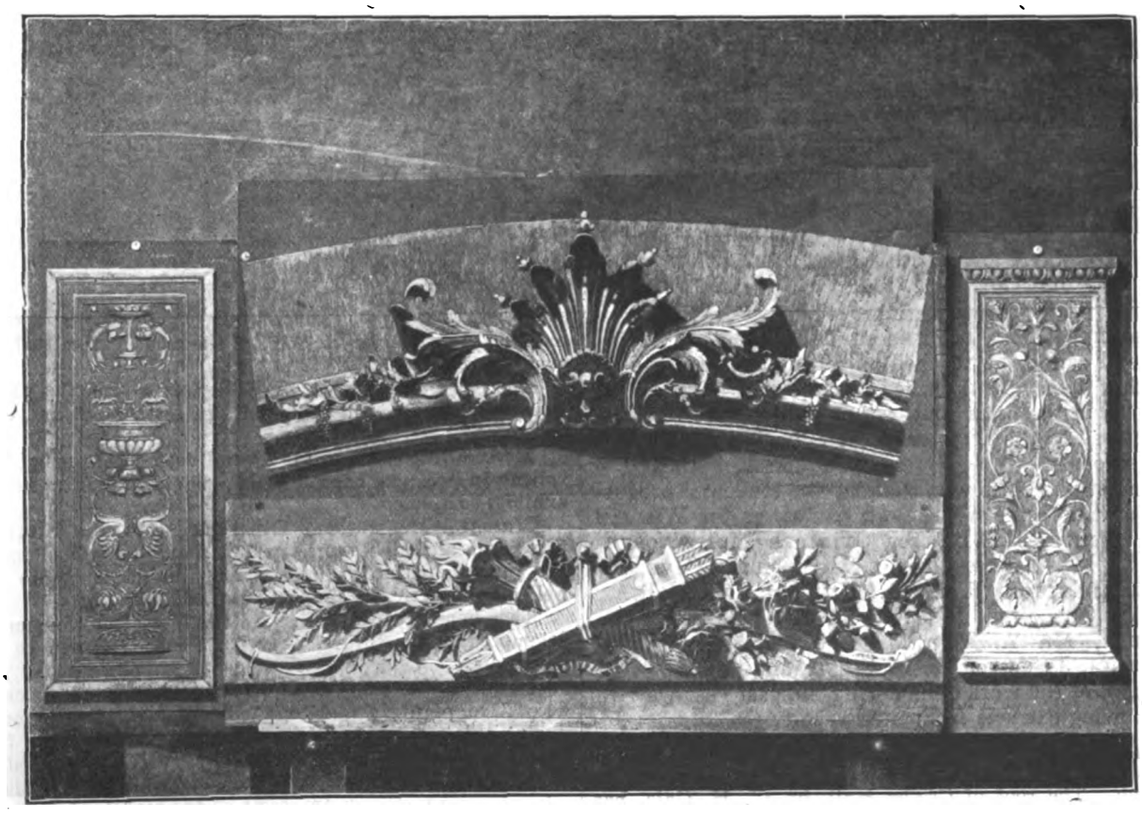

Fig. 4.—WOOD CARVING.

work done than in any previous session. The exhibits shown are quite a departure from hackneyed examples. Many of the students have used as *motifs* features of buildings recently erected.

Life Class.—Sir George Frampton, R.A., Messrs. Goscombe John, R.A., Banister Fletcher, and J. Hutton Freeman consider that the studies submitted to them are even better than last year, and again prove the advantage of instruction by means of quick studies which has been adopted.

Tylers and Bricklayers.—The specimens of cut brickwork exhibited are of exceptional merit, and the judges were struck by the working drawings, which evince a practical acquaintance with the work of the trade. The fine example of a cut brick font, executed by R. Fever, is decidedly unique, and illustrates the way in which the material may be used. He was a close competitor for the Banister Fletcher medal.

Wheelwrights.—The exhibits, although fewer in number than usual, are of considerable merit and show much care.

Digitized by Google

Wood-Carvers.—The judges are glad to see that a very good standard is maintained in this class, and they appreciate very much the skilful drawings that have been exhibited. They would like to see a little more wood-carving, and also think it desirable that the models should be presented with architectural surroundings when possible, and that the original sketches for the design should be exhibited. They would recommend that models of good architectural features should be added to this class.

Electric Wiremen's Work.—The judges were pleased to note that this class has met with success, as, although it was only initiated at the end of 1908, some very excellent examples of wiring for electric light, bells, and telephones have been installed. It is difficult to differentiate between the students, as such work is necessarily of a joint nature.

CONCRETE REINFORCED BY NAILS.*

THE paragraph in our last issue under "Our Contemporaries from Over-Seas," on the paper in *The Engineering Record,* has excited considerable interest amongst our readers, and we therefore reproduce the report from our contemporary:—

Concrete reinforced by metal to sustain tensile stresses produced by flexure has been investigated most fully in all its possibilities during the last twenty years. The strength of reinforced concrete in compression, both direct and due to flexure, has also received much attention more recently. By the very character of concrete, which has a tensile and shearing resistance many times lower than its compressive strength, and on account of the possibility of reinforcing this material in one direction or another, it lends itself most readily to experimental research in several directions, such as the effect of lateral restraint or enhanced shearing resistance. It is true that concrete is not a sufficiently homogeneous material to afford exact experimental data which could be utilised in comparative studies to a nicety. But for structural materials and engineering purposes it is important to obtain even gross experimental results and, in many cases, such information is sufficient.

Such gross results will be presented in the following notes on the compressive resistance of concrete cubes reinforced by wire nails. The writer claims a fairly extensive acquaintance with the literature of reinforced concrete and he does not recollect to have encountered mention of tests made on concrete reinforced in this manner.

That no attention was paid to increasing the compressive resistance of concrete by the embedding of wire nails, cut wire, nuts, and similar material, is not surprising because it is, on its face, very uneconomical and does not promise commercial success. Wherever such means of reinforcing may have occasionally been used, it probably has not been considered important enough to make a series of tests which would be worth while recording. The great compressive strength that can be developed in concrete reinforced in this way must have remained entirely undisclosed.

The occasion which led to the series of tests described in this paper arose from conditions requiring the use of an initially plastic material which should fill certain spaces, harden to an imperishable state, and develop within a comparatively short time great compressive resistance without sustaining much deformation.

Some time ago it was deemed advisable to fill the compartments of a large steel casting with a material as described above. This casting formed a pedestal of an important bridge being constructed by the Department of Bridges of the City of New York. Mr. C. M. Ingersoll, consulting engineer, suggested the use of concrete reinforced by wire nails or cut wire, and ordered tests of this material to be made by the Cement Testing Bureau of the department. The results of these tests were so satisfactory that the mixture was adopted for the filling.

Altogether 75 test cubes were made, 60 of which were broken, the remaining 15 being left for age tests. Those broken consisted of 57 specimens reinforced by wire nails, one by cut wire, and two by scrap iron consisting of nuts, nails and clippings. Of those reinforced by wire nails 55 were 6-inch cubes and two 12-inch cubes. These were the only 12-inch cubes, the remaining specimens being all 6 inches.

Several standard brands of Portland cement were used in the making of the cubes but no separation of the results with respect to the brands has been made in this paper. The cubes were made of a cement and sand mortar and standard eightpenny wire nails, 0.1 inch in diameter and 2½ inches long. In all but two cubes the proportions of the mortar were 1 to 2. The aggregates were proportioned by weight as follows: 4 lb. and 2 oz. of Portland cement, 8 lb. and 4 oz. of sand, and 11 lb. of wire nails.

The cement and sand were first mixed dry, and about 12 per cent. of water was then added, making a fairly stiff mortar. The nails were then added and mixed with a trowel in the usual way, the same as for broken stone concrete. They were slightly wetted before mixing. The concrete was then placed in the forms in layers of about 1 inch and tamped. The upper surface was finished with 1 to 2 mortar. The forms were removed in about 48 hours. They were then kept in the

* A paper read before the recent Convention of the American Society for Testing Materials by Leon S. Moisseiff.

air and wetted daily by sprinkling until used. The weight of the concrete so made was 196 lb. per cubic foot. The cubes looked smooth on the outside the same as plain concrete cubes, except for light brown spots, showing discoloration of the concrete by the embedded nails wherever the latter were exposed.

The accompanying table contains the results of all the tests, tabulated as to age of specimens, and the average, minimum and maximum resistances of each group. As seen from the table there are 12 such groups varying in age from one week to eighteen months.

The tests were made in a hydraulic press of 350 tons capacity, and the pressure was read off a pressure dial. The accuracy of the machine was within 3 per cent. In the case of the 12-inch cubes an 1,100-ton machine was used. The pressure was applied as slowly and as gradually as such machines will permit. The first indication of noticeable deformation was given by the flaking off of the sides, exposing the embedded nails. This may be termed the elastic limit, but it was not recorded in all cases. Where recorded, the elastic limit varied between 60 to 80 per cent. of the ultimate strength.

The crushing strength was considered to be attained when the deformation became excessive. After this point was reached the cube was rapidly squeezed without any increase in pressure—on the contrary, the pressure could be much decreased. When the squeezing was carried sufficiently far the cube would break apart when removed from the machine and dropped on the floor.

The results of the tests as tabulated speak for themselves. Little can be added in discussing them. The most striking fact is that a greatest resistance of 17,800 lb. per square inch was obtained on a cube fifteen months old, a figure unheard of in reinforced concrete testing. That this figure is not accidental is borne out by the fact that the companion test cube developed a resistance of 16,670 lb. per square inch, and that two 12-inch cubes, reinforced by 25 per cent. more nails than the other cubes, attained in eight months a resistance of 15,300 lb. per square inch without failure, the limit of the largest machine having been used.

The most important phenomena developed are, however, the comparatively high resistances obtained within seven days and one month, and the small variations in the strength of the various cubes at the age of seven days. The average compressive strength, as will be seen from the table, developed by 17 cubes was 3,010 lb. per square inch, with a minimum value of 2,770 lb. and a maximum of 3,330 lb., or about 10 per cent. either way. The average strength of 16 cubes at the age of one month reached 5,645 lb. per square inch, an increase of 88 per cent. in three weeks. The growing strength of the cubes with their age can be plainly seen from the table.

The cube reinforced by cut wire, instead of wire nails, failed at the age of seven days at 1,945 lb. per square inch, or under a pressure of only two-thirds of that of the wire nail cubes. The two scrap-iron cubes, while somewhat stronger, did not make a better showing.

From the proportion of wire nails used the high cost of such concrete is at once apparent. Eighty-eight pounds per cubic foot of concrete, or 18 per cent. by volume is certainly expensive reinforcing. The cost of concrete so reinforced will be about $2.30 per cubic foot, and the high cost precludes its use to any considerable extent. There are, however, many instances where a material which combines so high a compressive resistance with the advantages of concrete will find its applications. Thus, for instance, where column footings are to be raised or the foundation has settled, it might be found very convenient to utilise concrete reinforced by nails to fill the spaces. The plasticity of the material which can be made to fill all kinds of spaces, and the great strength developed in seven days will, in many cases, be of sufficient advantage to cause its adoption.

Aside from the practical considerations of utilisation, the tests described in this paper have a theoretical bearing. They illustrate in an extreme manner how the compressive strength of a material may be increased by reinforcing its shearing resistance. The nails actually reinforce the shearing planes in all possible directions, and thereby develop the high compressive resistance of the material. The tests thus shed a light on the internal stresses of a body in compression.

The Glasgow Society of Artists have decided to hold their seventh exhibition in the galleries of the Royal Glasgow Institute of Fine Arts, Sauchiehall Street, during October this year. Five new members have been elected.

ILLUSTRATIONS.

BIRMINGHAM UNIVERSITY.—ENTRANCE—DETAIL OF ENTRANCE—TESTING LABORATORY—ELECTRICAL LABORATORY—DRAWING STUDIO—A CORRIDOR.

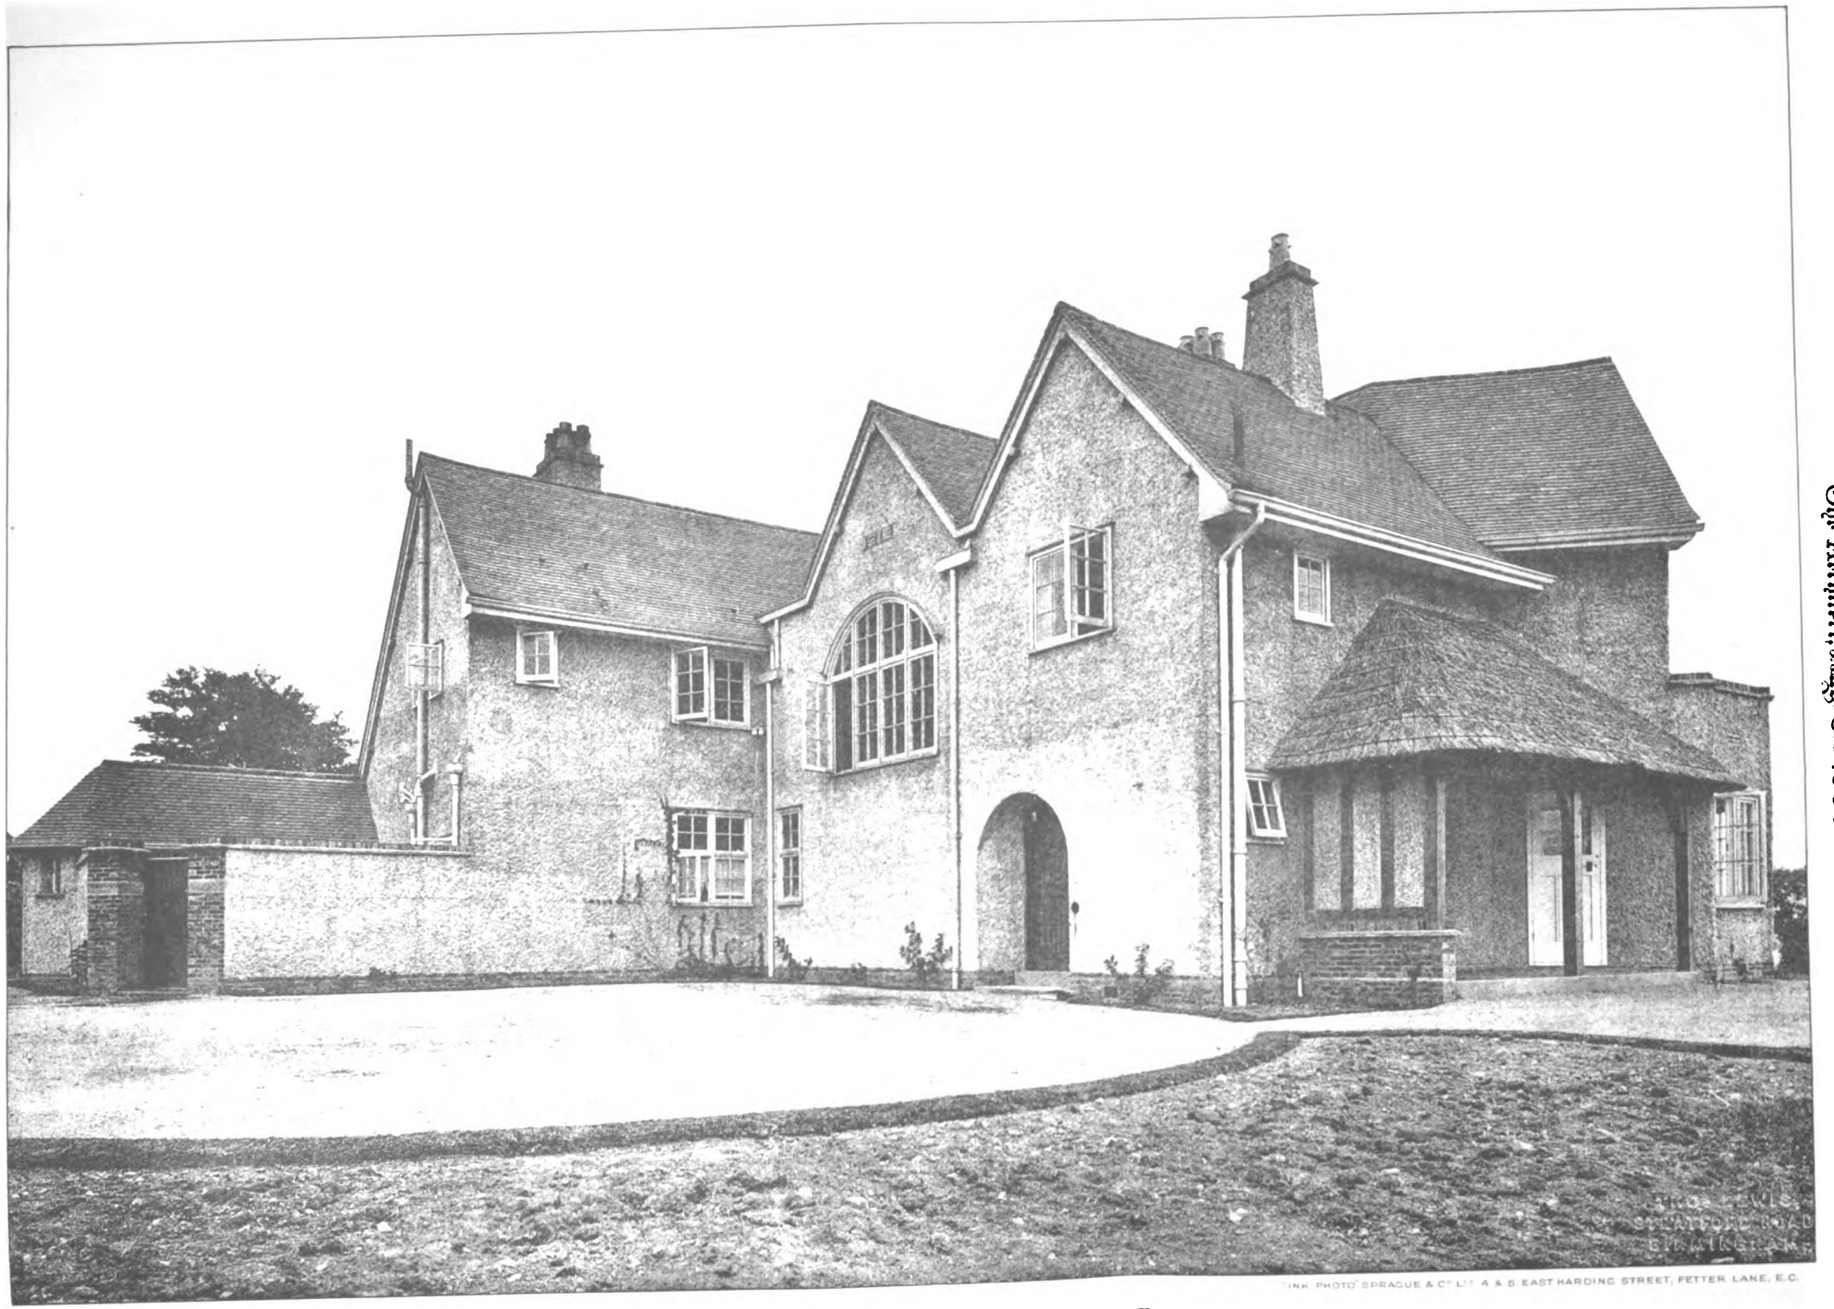
THE main entrance to Birmingham University is in the central block, which contains the Entrance Hall and the Assembly Hall, illustrated by us last week. It is approached in a direct line from University Road; the visitor passes through one of five vaulted archways under the reading-room of the Harding Library, which occupies the centre of the main frontage, and on past the Chamberlain Tower. Above the entrance doorways are nine sculptured figures by Mr. Henry Pegram, A.R.A., representing from left to right Beethoven, Virgil, Michel Angelo, Plato, Shakespeare, Newton, Watts, Faraday and Darwin. In the spandrils of the window above are carved the arms of the neighbouring counties, with the University arms on the keystone. To the right of this main block is the electrical and civil engineering block. The main laboratory contains the various apparatus for testing the strength of materials and for hydraulic work, and most particularly the 300-ton testing machine, which is large enough to deal with built-up structural members of a practical size in tension, compression and bending. There are two electrical laboratories—that on the first floor contains the light apparatus, that on the ground floor the heavy running machinery. The general contractor for the University building was Mr. Thomas Rowbotham, and the architects were Sir Aston Webb, C.B., R.A., and E. Ingress Bell.

HOUSE ON THE LICKEY HILLS, WORCESTERSHIRE.—S.W. ELEVATION.

THIS house, the country residence of Mr. Edward Cadbury, was designed for a very hilly, exposed situation. The walls are faced with thin black country bricks with thick white joints, and the roofs covered with hand-made tiles. Messrs. J. & A. Brazier, of Bromsgrove, were the builders, and Messrs. Cossins, Peacock & Bewlay, of Birmingham, the architects.

BEACON WOOD, LICKEY HILLS, WORCESTERSHIRE.—ENTRANCE FRONT.

THIS house, the country residence of Mr. George Cadbury, jun., was built by Messrs. J. & A. Brazier, of Bromsgrove, from designs by Messrs. Cossins, Peacock & Bewlay, of Birmingham. The exterior is faced with silver-grey rough-cast, the main roof being covered with hand-made tiles. The loggia and verandah are thatched.



LIVING ARCHITECTS.—OXFORD COLLEGES.

WE shall continue our series of drawings by Mr. Ginsbury of "Living Architects," and also the series of illustrations of the Colleges of Oxford in September.

The Aberdeen County and Municipal Buildings Commissioners had before them at their annual meeting last week a report by Mr. William Kelly, architect, on the state of the freestone of the Old Tolbooth. Within the past ten years the masonry has begun to show signs of exfoliation, and Mr. Kelly recommended that the loose surface of the stonework be scaled off and flushed up with cement, and the whole treated with a preserving solution. The Commissioners approved of the report, the cost to be borne equally by the county and the city. The Tolbooth was erected in the early part of the seventeenth century.

The Following Results of Examinations in the Department of Architecture are published by the Sheffield University:—First Year.—First Class: John H. Odom; Second Class: George A. Booker, Henry B. Leighton. Second Year (for certificate).—First Class: John C. P. Toothill; Second Class: Harry B. S. Gibbs, Walter Noble, Stanley H. Williams. The following students in the Department of Architecture have passed the following examinations of the Royal Institute of British Architects:—Preliminary, George A. Booker; intermediate, George R. Bower; final, Herbert G. Warlow.

ST. MARY'S CHURCH, WARE, HERTS.

WARE.*

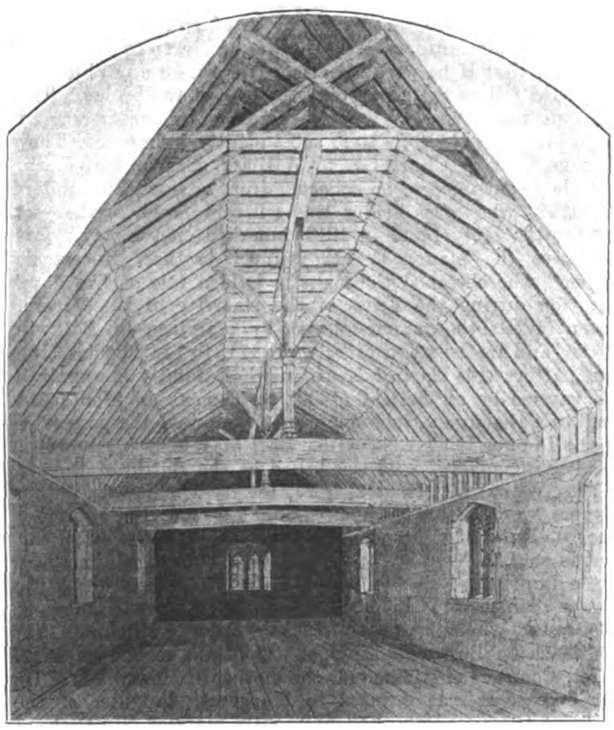
WARE, a thriving market town of Hertfordshire, derives what importance it has from the fact that it is the largest malting town in England. The number of malt-houses (about eighty) is its most noticeable feature, and we are told that when malt was taxed the amount collected one year was as much as 200,000*l.* Ware is of considerable antiquity, having been known to the Romans, their Ermine Street crossing the Lea a little above the town. At that time Hertfordshire formed part of the Roman province of Flavia Cæsarensis, but on the conquest of England by the Anglo-Saxons the county was merged partly in Mercia and partly in Essex. Roman remains have been found at different times in the vicinity of the town.

In the year 896 A.D. history relates that the Danes brought their war vessels up the Lea, anchored them near Ware, and laid siege to Hertford. The people of London attacked their encampment but were repulsed, and the following year King Alfred the Great commenced operations against them. He is said to have constructed fortifications and set men to work to divert the stream, in order to prevent the Danes from bringing out their ships. The Danes, finding their vessels stranded, abandoned them and retreated to the West of England. The precise locality of the Danish camp is uncertain, but it was somewhere between Ware and Hertford, and it is not clearly known what was the exact nature of the operations conducted by Alfred.

In Domesday the name of the town is given as "Waras," but in other old writings it has the name of "Gware" and "Gwaris." Cussans says:—"It is probable that the name of this town may have been derived from the weir built across the Lea at this place on the invasion of the Danes. This at least is the popular account, unsupported, however, by any positive evidence. Stowe says the town was built as early as the year 941. It must, however, have been for many years an inconsiderable village, for at the time of the compilation of Domesday it contained less than 120 inhabitants, including serfs, and was only worth 45*l.*"

The translation of Domesday given in the recently published "Victoria History of Hertfordshire" runs as follows:—"In Brachinges [Braughing] Hundret Hugh de Grentmaisnil holds in Waras [Ware] 24 hides. There is land for 38 ploughs. In the demesne there are 13 hides, and on it are 3 ploughs. There could be 3 more. There are 38 villeins and (cum) a priest and the reeve of the ville, and (cum) 3 Frenchmen and 2 Englishmen have 26 ploughs and a half plough. There are 27 bordars and 12 cottars and 9 serfs. Under the Frenchmen and the Englishmen are 32 men between villeins and bordars. There are 2 mills worth 24 shillings and 400 eels less 25; and other men have 3 mills producing 10 shillings yearly. Meadow is there sufficient for 20 plough teams. Woodland to feed 400 swine. There is an enclosure for beasts of the chase, and 4 arpents [about 12 acres] of vineyard just planted. The total value is 45 pounds; when received it was 50 pounds; T.R.E. [in the time of Edward the Confessor] also 50. This manor Anschil of Waras [Ware] held, and 1 sokeman, his man, had there 3 hides, and another sokeman, Earl Guert's [Harold's brother Gyrth] man held half a hide. Either could sell. These two, after King William came, were attached to this manor. They did not belong to it in King Edward's time—so the shire moot testifies."

Hugh de Grentmaisnil was a follower of William the Conqueror, and in return for his services large grants of land were bestowed upon him. The manor of Ware remained in his family till near the close of the twelfth century, when it passed by the marriage of his great-granddaughter to the Earl of Leicester. It subsequently passed to Saher de Quincy, Earl of Winchester. He freed the town from the toll levied by the Corporation of Hertford on all traffic by horses or carts crossing the bridge, by breaking the great iron chain which was put across the bridge to prevent a road here to the disadvantage of Hertford. Saher is said to have informed the bailiff of Hertford, who had the keys, that if he were dissatisfied or raised any objection he should follow the chain over the side of the bridge. The trade of the town was greatly increased by the freeing of the bridge, but the tolls were subsequently re-imposed. They were granted by Charles I. to William, Earl of Salisbury, and they continued to be collected from non-resident traders till 1900, when the bridge was entirely freed. Saher set out for the Holy Land in 1219, but died on the way. His son gave the manor to his younger brother, Robert de Quincy, who obtained the right to hold a fair of five days' duration during the Feast of the Nativity of the Virgin. Later (1262) the manor passed by marriage to Baldwin Wake, and in the reign of Edward III. to Sir Thomas Holland, afterwards Earl of Kent, in whose family it remained till carried by an heiress (1409) to Thomas de Montacute, Earl of Salisbury. Subsequently it came into the possession of the famous Richard Neville, Earl of Warwick, known as the "Kingmaker," who was killed at the Battle of Barnet. When Warwick's estates were forfeited this and other manors were bestowed upon King Edward IV.'s brother George, Duke of Clarence, who was subsequently attainted, and is said to have been drowned in a butt of Malmesbury while imprisoned in the Tower. On the duke's death the manor came into the possession of Richard Duke of Gloucester, who subsequently became King of England. On his death on Bosworth Field (1485) it was settled on Margaret, Countess of Richmond, the mother of Henry VII. On her decease it was granted to Margaret, daughter of the Duke of Clarence, who had previously married Sir Richard de la Pole, and was mother of Cardinal Pole. This lady subsequently became Countess of Salisbury, and when 70 years of age was accused of favouring the old religion and was sentenced to death, without even the ceremony of a trial, and beheaded in 1541 in the Tower. With her the noble and illustrious House of Plantagenet became extinct. On the accession of Queen Mary she restored the manor to the grand-daughters of the Countess of Salisbury, and one of them, Katherine, sold it, about 1570, to Sir Thomas Fanshawe, Queen's Remembrancer of the Exchequer. He was succeeded by his eldest son, Sir Thomas Fanshawe, who was appointed ambassador to the Court of Spain, and afterwards filled the posts of Secretary for War and Treasurer of the Navy. He died at Madrid in 1666, whither he had been sent by Charles II. as Envoy to Portugal and Spain, but his remains were brought to England and deposited in All Hallows (All Saints') Church, Hertford. They were finally buried in a vault under St. Mary's Chapel, Ware, in May 1671. The second viscount was the last of the family who possessed the manor, for he was compelled for want of money to sell it to Sir Thomas Byde, a brewer, of London, about 1700. In 1846 it was alienated to James Cudden, and in 1853 sold to Daniel de Castro, and again in 1869 to Mr. George Rastrick.



The manor-house is situated to the west of Ware Park, about a mile from Ware. The present building, about which there is nothing of particular note, was erected by Sir Thomas Byde on the site of the house occupied by the Fan-

shawes. A very fine avenue over half a mile long runs through the park, which contains some trees of magnificent proportions, said to have been planted by one of the Fanshawes.

There were anciently in the town two religious establishments which various writers appear to have more or less confounded with each other. One of these was known as the "Alien Priory of Ware," a Benedictine monastery, with respect to which Dugdale says:—"Hugh de Grentmaisnil, lord of this town, gave the church of St. Mary here with the tithes thereunto belonging and two carucates of land before the year 1081 to the monks of St. Ebrulf at Utica in Normandy: whereupon it became a cell to that abbey and in process of time was so well endowed that upon the seizure of the alien priories by King Edward III. during the wars with France this was farmed at 200*l.* per annum. After the suppression of these foreign houses this was given 3 Henry V. to the monks at Shene. King Henry VI. for some time annexed it to the abbey of St. Mary near Leicester, but it was afterwards restored to Shene, and, as parcel of its possessions, was granted by King Henry VIII. to Trinity College in Cambridge." A distinct foundation was the Priory for Friars of the Order of St. Francis. This had no connection with the parish church, and was, on the dissolution of the monasteries, given by King Henry VIII. to

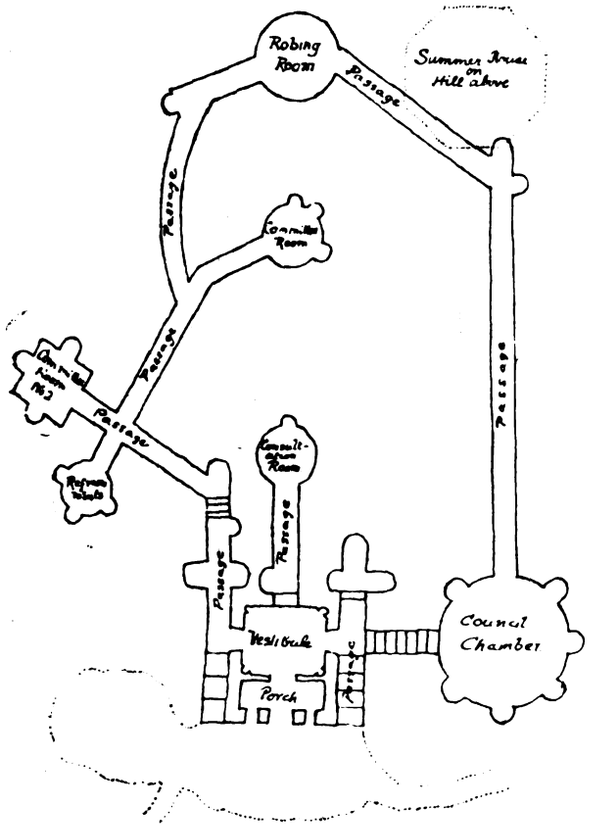
OPEN ROOF, WARE PRIORY, HERTS.

one Thomas Byrch, a yeoman of the Crown. The remains of the buildings of this Franciscan priory are incorporated in the building known as "Ware Priory," which by the kind permission of the occupant, Robert Walters, Esq., we have had the pleasure of inspecting this afternoon. The remains consist for the most part of ancient walls fitted up and accommodated to the purposes of a modern dwelling. A small obtusely pointed arch within the north-east angle of the building is supported by corbels displaying the upper parts of human figures, one of which appears to be clad in mail.

The church is a large and handsome cruciform building of flint and stone, in a good state of preservation, with a lofty embattled tower surmounted by a short, thin spire. The body of the church is in the Decorated style of architecture, whilst the chancel and tower are Perpendicular. The tower contains a peal of eight bells. The church is dedicated to St. Mary, and appears to have been erected towards the end of the fourteenth century. The chancel is said to have been built by Joan de Holland, the "Fair Maid of Kent," the wife of Edward the Black Prince and mother of Richard II. The interior is both roomy and striking. The fine chancel arch, the beautifully moulded columns which divide the aisles from the nave, and the lofty, open timbered roof contribute a grandeur and beauty which cannot fail to excite admiration. The large memorial window in the chancel represents the Crucifixion and other scenes illustrating the Passion of our Lord. The fine window in the north transept is designed to illustrate the Te Deum. Near the bottom of this window may be seen the wife of the Black Prince presenting a silver model of the church which she has dedicated to the service of the Supreme Being. Separated from the chancel by a new and handsomely carved oak screen and double arch with a slender clustered shaft of polished Purbeck marble in the middle is the lady chapel, spoken of as "the burying-place of Ware Park." Prior to the restoration of the church the mural marble monument now in the south transept of Sir Richard Fanshawe rested here. In the chapel are a piscina, sedilia, and aumbries. The west end of the chapel is separated from the south transept by a carved oak screen. The south transept also appears to have been made use of as a chapel, as shown by the piscina in it. When the church was restored many of the monuments were removed, and either lost or set up in other places. An altar tomb in the north transept had at one time some good brasses, but the churchwardens have put it on record that they were stolen several years ago by a dishonest parish clerk. The stone matrix with the bitumen in which the brasses were embedded still adhering to it is laid down in the south transept. Of the brasses

ST. MARY'S CHURCH, WARE, HERTS.

which formerly existed on the floor of the church two or three only are left. One now placed on the wall of the south transept to the memory of William Pyrey and his wives, Agnes and Alice, is remarkable. It would appear from the small brasses beneath the figures of the wives that he had five sons and five daughters by each of them. On the south side of the church a tomb in the churchyard to Dr. William Mead records that he died in 1682, "aged 148 years, 9 months, 3 weeks, and 4 days," a remarkable testimony, if it may be believed, of the salubrity of the county and the longevity of its inhabitants.



The font, placed just inside the western door to typify the entrance by baptism of children into the Church of Christ is an exceedingly interesting object. It is octagonal in shape, and supported on a base richly carved and moulded. On each side a saint sculptured in high relief is represented, and at the angles are the instruments of the Passion alternating with angels. The figures represented on the panels are St. George killing the dragon; St. Catherine holding a sword and a wheel by which she suffered martyrdom; St. James with a book, Palmer's staff and scrip; St. John the Baptist holding a book and Agnus Dei; the Virgin Mary, with a lily growing from a vase by her side; St. Louis holding a scroll and sceptre, surmounted by a fleur-de-lys; St. Margaret piercing a dragon with the foot of a cross; and St. Christopher carrying the infant Christ on his shoulders. The execution of the font is, from the fashion of the armour worn by St. George, ascribed to about the year 1380. The figure of this saint, although more crude in workmanship, is said to be in nearly every respect similar to the magnificent effigy of the Black Prince in Canterbury Cathedral. (Cussans, Thorne, and others.)

The registers date from 1553, and are complete, except that several pages are missing between the years 1706 and 1730.

The church was restored in 1850, and again internally in 1881, when the mouldings and tracery were re-chiselled and a good deal of new work inserted.

Amwell House, close to Ware railway station and now the Ware Grammar School, was formerly the residence of the Quaker poet, John Scott, generally known as "Scott of Amwell." In the poet's time the grounds attached to his house attained a good deal of celebrity from the fact that they contained a grotto constructed by Scott, with the aid of a native of Ware named Frogley. The grotto is a curious one, embellished with flints, shells, &c., and is understood to be about the best-preserved specimen of its class remaining. It is cut in the side of a chalk hill, and consists of seven different chambers all connected by underground passages. Thorne, writing about 1876, says, "The chambers now bear such titles as the Palm Pillar Room, the Hermit's Cave, and the Quaker's Room." The precise object which Scott had in view in constructing his grotto is not known. Above the grotto are two small summer houses, on the floor of one of

SCOTT'S GROTTO, WARE.

From a drawing by Mr. R. T. Andrews in the East Herts Archæological Society's Transactions, 1899. *(By permission.)*

which the date "1764" appears worked in small pebbles of a different colour to those surrounding it. There is also a small summer house which is said to have been Scott's favourite retreat. The grotto attracted the notice of Dr. Johnson, who is said to have called it "Fairy Hall," and to have "excited in Mr. Thrale and his lady the curiosity to see the gardens and grotto."

No paper on Ware would be considered replete without an allusion to "John Gilpin," that celebrated "citizen of famous London town," immortalised by the poet Cowper. It appears that Lady Austen, a friend of Cowper's, told him the story of Gilpin one evening, which so tickled his fancy that he was kept awake during great part of the night after hearing it, and next morning turned it into a ballad. It first appeared in the *Public Advertiser*, but without the author's name. It was subsequently reprinted in many forms, and was the talk of all classes; while prints of "John Gilpin" were to be seen in many of the shop windows. In 1785 Cowper wrote to a friend:—"I return you thanks for a letter so warm with the intelligence of the celebrity of 'John Gilpin.' I little thought when I mounted him upon my Pegasus that he would become so famous. I have learned also . . . that he is equally famous in Scotland, and that a lady there had undertaken to write a second part on the subject of Mrs. Gilpin's return to London, but, not succeeding in it as she wished, she dropped it. . . ." (H. Morley.)

On page 454 of William Hone's "Table Book," published in 1827, is an engraving depicting "Mrs. Gilpin riding to Edmonton." The good lady is astride a three-barred gate, and the following verses, with "the sketch (probably from the poet's friend Romney) was found, in the handwriting of Cowper, among the papers of the late Mrs. Unwin." Mrs. Unwin was the wife of the clergyman with whom Cowper lived for some time at Olney, in Bucks, after the death of her husband. The verses run:—

Then Mrs. Gilpin sweetly said
Unto her children three:
"I'll clamber o'er this stile so high,
And you climb after me."

But having climb'd unto the top
She could no further go,
But sate, to every passer-by,
A spectacle and show.

Who said, "Your spouse and you this day
Both show your horsemanship,
And if you stay till he comes back,
Your horse will need no whip."

Notwithstanding the King's prohibition, a tournament was held at Ware in the 25th year of the reign of Henry III., when Gilbert de Mareschall, Earl of Pembroke, lost his life by falling from his horse and being trampled upon. One of his knights was also slain in the diversion, and several others wounded.

The most noted of the local antiquities, and, indeed, one of the curiosities of England, is the "Great Bed of Ware," which was famous even in Shakespeare's time, and is referred to by him in "Twelfth Night." It is said to have belonged to Ware Park, but was kept at the Crown Inn until that building was demolished in 1675, when it was removed to "The Bull" and afterwards to the "Saracen's Head." It is now at Rye House.

As might be expected, some of the private houses and premises in Ware contain features of archæological interest. In the house occupied by Mr. Ward in the High Street there is a richly carved mantelpiece, some old oak panelling and ornamental plastering, and, in the drawing-room, what is known as "the waggon ceiling." In the shop of Mr. Price, printer and stationer, in the High Street, may be seen an old carved ceiling, believed to be coincident with a carved mantelpiece bearing the date "1648" in a private room upstairs. The out-premises of Mr. R. W. Harradence in the High Street contain some window openings and doorways with Gothic heads and mouldings which Mr. R. P. Andrews, of the East Herts Archæological Society, is of opinion "point decidedly to the existence of a perpendicular building" dating from "about the close of the fourteenth or the middle or early part of the fifteenth century."

It is recorded by Cussans that "at a Court held in 1670, it was decided that a ducking-stool should be erected within the manor for the punishment of scolds and termagant women"; and on a subsequent occasion, being found out of order when its services were about to be called into requisition, the bailiff was fined fifteen shillings for his neglect of duty.

In 1831, when some ground was being opened to form a new lock in the valley of the Lea, the skeleton of a man was found, and, some nine inches deeper, a steelyard, which appeared to be of Roman origin. The weight belonging to the instrument was found a few inches lower still, together with a brass coin of Domitian. Close by was also found a curiously worked brass candlestick, an iron axe-head, and a finger ring. Subsequently, at a little distance away, was found a pin such as was used by ladies for their hair, a Roman key, two stones which appeared to have been worked for the purpose of grinding, a coin of Severus, and a large earthen vessel. Four coffins of stone with lids nine inches in thickness were also found when a ditch was dug across a field called "Bury Field." In 1899, when excavations were made in this field for the site of Messrs. Allen & Hanbury's factory, numerous relics of Roman occupation were found, a full account of which is given by Mr. Andrews in a paper published in the Transactions of the East Herts Archæological Society of 1900. The objects consisted of "pottery, small coins, glass, and the remnant of a small bronze spear-head."

The New River runs through Ware, and its sources are in the immediate neighbourhood—Chadwell, about a mile east of Hertford, and "Emma's Well," at Great Amwell. The river was designed to supply London with water, and was constructed by Sir Hugh Myddelton, Bart., with the aid of monetary assistance from the Government, in consideration of which King James took "a moiety of the interest in profits to arise from the New River for ever." So valuable has this property become that the original founders' shares now command fabulous prices.

Digitized by Google

I cannot close this somewhat lengthy paper without a brief reference to Izaak Walton, the author of the "Compleat Angler," who spent a great deal of his time by the Lea in the neighbourhood of Ware and Great Amwell; to Charles Lamb, who passed much of his childhood at Blakesware, some four or five miles from Ware, and who has commemorated his stay in his essay entitled "Blakesmoor in H——shire"; and to William Godwin, sometime minister of the Independent Chapel at Ware, who in 1793 wrote a book entitled an "Enquiry concerning Political Justice." Of "William of Ware," who is said to have been the teacher of John Duns Scotus, a distinguished theologian and Franciscan writer, I have been able to obtain little or no information.

ARCHITECTURE AND TOWN PLANNING.*

IMPROVEMENTS in the laying out of our cities seem ever before us, and yet we do not succeed in obtaining any decided model which could serve for all time and for all cities. In new developments one finds, at times, unpardonable blunders and want of foresight; and, in old cities, wasted opportunities frequently stare us in the face. Take one instance only—Margate. In walking up to Cliftonville the painful result of letting building owners do what they like is apparent—blocks of bricks and mortar jut out at every conceivable angle, and muddle takes the place of what might easily have been a fine stretch of sea front right away to Kingsgate. Innumerable similar instances could be cited.

The subject of town planning has always been a favourite one with architects; and in the literature of within the last hundred years one finds Sydney Smirke, James Pennethorne, and other architects bringing to bear their taste and their skill in the earnest endeavour to improve this great London of ours. But, even as now, their efforts fell upon deaf ears. Through want of enterprise, and even of common-sense on the part of the ruling authorities, fine and cheap opportunities were given the go-by—and then ground values ran up, stopping, on the score of price, any chance of revival.

Whilst on the subject of price of land there can be little doubt that our system of leaseholds, which in London dominates building transactions, does to a certain extent affect town planning. Freeholders as a rule, particularly the great ground landlords, do not give away much land for the sole purpose of public improvements, and certainly the man who only holds an eighty years' building lease cannot be expected to sacrifice much of his 10*s.* a foot superficial ground for the benefit of his fellow-citizens, so that, between the two, good town planning goes to the wall. Now, in Paris, when it was Baron Haussmannized prior to 1870—and subsequently to 1870—the expropriations were taken in hand by the city authorities; the ground for building was laid out in plots and the freeholds sold by tender. Thus if any purchaser felt a desire to effect some improvement in the re-alignment of his plots, he knew that if any advantage accrued thereafter he would be the gainer. In London the authorities for making public improvements do so, as a rule, either under special Acts of Parliament, or under that well-tried and marvellously comprehensive statute known as Michael Angelo Taylor's Act. It cannot be denied that many more widenings of narrow important thoroughfares would take place if the large ground landlords of London co-operated more with the authorities, by way of reduced prices, than they are in the habit of doing—thus lessening the enormous cost of carrying out what, after all, are schemes benefiting generally the whole community, and often particularly the great ground landlords.

It is somewhat curious that a practical suggestion to beautify and make more commodious the city of London came some years back from a gentleman who had passed a great part of his life in one of our Colonies—I refer to the late Mr. William Westgarth—and it was due to him that I, and others, commenced to lay down our respective views on London improvements.

In December, 1883, that gentleman offered the Society of Arts a large sum of money to be awarded in prizes for essays on the best means of providing dwellings for the London poor, and on the reconstruction of Central London. Several architects competed for the prizes, and I was one of the fortunate winners of 100*l.* for an essay sent in on December 31, 1884. Since then, by papers read at the Royal Institute of British Architects, and at the Surveyors' Institution, the subject of improvements in London has been well brought to the fore. Much credit is due to Mr. Ebenezer Howard, the author of "Garden Cities," for that patient and far-seeing work which has produced such fine results in the way of town planning improvements. Continued and deep interest in this grand Metropolis should always be uppermost in the mind of every architect, and indeed of every citizen. I venture to think that such a catastrophe as that which happened to the City of London after the Great Fire in 1666 would be impossible to-day. We all know that Sir Christopher Wren and Sir John Evelyn prepared plans for the rebuilding of that part of the City which was destroyed, and that those plans were completely upset, and the opportunity for a fine piece of planning for ever lost, not on account of cost, but because an obtuse authority pooh-poohed the schemes which the superior intelligence of Wren and of Evelyn had evolved.

Successful town planning is not so easy as it looks. Given large vacant areas to deal with we must at the same time provide large heads to evolve satisfactory plans. Turin, for example, had large vacant areas, and the Italian architect or engineer who laid out the city did it on those strict and straight geometrical lines which form a subject of regret to all lovers of the picturesque, who can perhaps make up for their disappointment by coming back to England and viewing that incomparable bit of perhaps accidental embodiment of the picturesque and architecturally beautiful known as the "High" of Oxford.

Take again the recent clearances and town planning of Rome; ambitious and inappropriate architecture obtrudes itself on streets too wide and too straight, and dwellings for the poor of Rome are more like plaster palaces. The Ringstrasse of Vienna we in London cannot hope to imitate; Paris has had its way and its day; Berlin is being, in parts, transmogrified, and deeply afflicted with that disease which appears spasmodically in London, known as "l'art moderne." It still remains for little Brussels (and other parts of Belgium) to hold up its head as the best exponent of what is grand, beautiful, and appropriate in the way of town planning.

And what are we doing in London? Great and expensive clearances have taken place; the Corporation of the City of London can well be congratulated on its liberality and on its wisdom. The Tower Bridge and its approaches, notwithstanding the sneers at its so-called sham bridge architecture, is an everlasting tribute to energy and foresight, and the widening of London and Blackfriars Bridges will not be forgotten by City pedestrians and drivers. Many pieces of expensive and extremely useful widenings of streets are also due to the Corporation, and the value of its co-operation is to be found in Queen Victoria Street and the Victoria Embankment, by which the old and sometimes despised Metropolitan Board of Works were enabled to lay the indelible mark of its finger upon two unquestionably grand results of its wisdom and of its enterprise.

Then let us, for a moment, glance at more recent examples of town planning as we may call it. "Kingsway" and "Aldwych" are before us. Large sums of money have been expended on these street improvements, and when the sites are all let and the thoroughfares become real business centres, I do not know that we shall have much to grumble at in the way of alignment. Personally I should have preferred the southern end of the new street to have discharged itself into a circus at the junction of Wellington Street and the Strand, making a more direct north and south railway line, but there it is, and the sooner the new sites are all covered with buildings the better.

Victoria Street, Westminster, constitutes a good London improvement, but many years elapsed before it became a success financially. It is a matter of detail, perhaps, but we must all have noticed the better effect of that street by reason of the substitution of white paint on the fronts in lieu of the dark and gloomy stucco which originally prevailed throughout the thoroughfare.

We should all, too, when thinking of town planning, pay due respect and admiration to Nash for the laying out of Regent Street and Regent's Park. Beautifully conceived are the whole of the terraces round the Park. Variety and charm greet us at every view; and although the fronts are all in the favourite stucco of the period, when repainted, as they are every four years, the general effect is decidedly pleasing. It will be noticed that Nash dealt with each terrace in the Park separately, and made each block one carefully designed architectural unity. This method was to a large extent followed in Regent Street, but the more recent demands of trade have led to alterations and additions which

* A lecture by Mr. Wm. Woodward, F.R.I.B.A., delivered at Hampstead on July 28 in connection with the Town Planning and Housing Exhibition.

Digitized by Google

have broken up these unities. The Commissioner of His Majesty's Woods and Forests is, however, securing piecemeal the restoration of these architectural unities, by demanding that a row of buildings between thoroughfares shall be treated distinct as architectural blocks, but not necessarily that all the blocks shall be of the same precise character. We shall thus secure variety of treatment, and avoid that monotony which one regrets in certain Continental cities.

One of my own favourite projects, which I have been at for over a quarter of a century, is the opening of the Mall to Charing Cross, and I have always held, and still hold, that a grand triumphal arch should have been formed at Spring Gardens, opening up to the Strand a magnificent vista of trees and avenue right away to Buckingham Palace. But, very unfortunately I think, we find that three small arches have been formed with a heavy superstructure of stone which completely mars and prevents the fine view up the Mall which we could so easily have had. The Coronation Avenue behind these arches is a very fine one, leading up to that memorial to our beloved Queen Victoria which we are all looking forward to as the triumph of the united efforts of Sir Aston Webb and Mr. Brock. This opening to Charing Cross is now in danger of being further marred by the retention of four or five houses at the corner of Spring Gardens which should certainly be removed.

Another recent effort at a public improvement is at the Marble Arch. Mr. Speaight—the author of that scheme—is entitled to the gratitude of all Londoners. It is, however, to be regretted that he did not, while he was at it, shift the Arch itself to the entrance to the new avenue across the Park, where the new piers and gates have been erected, and so give the Arch a *raison d'etre*. Now, the Arch, divested of its former surroundings, stands nakedly in isolation, and what might have been a thoroughly good work has been marred by an architectural blunder.

We are not equal to some of our forefathers in beautiful town planning. Everlasting gratitude is due to the wisdom and liberality of the owners of the land forming the squares of London. Take the neighbourhood of Pentonville, and that of the centre of the West Central District, and there you will find acres of land given up to the open spaces called "Squares" which provide lungs in place of what might have been unhealthy congested areas. And so with our Parks. I do not know any Continental city which can excel us in our parks, and they certainly cannot in our squares.

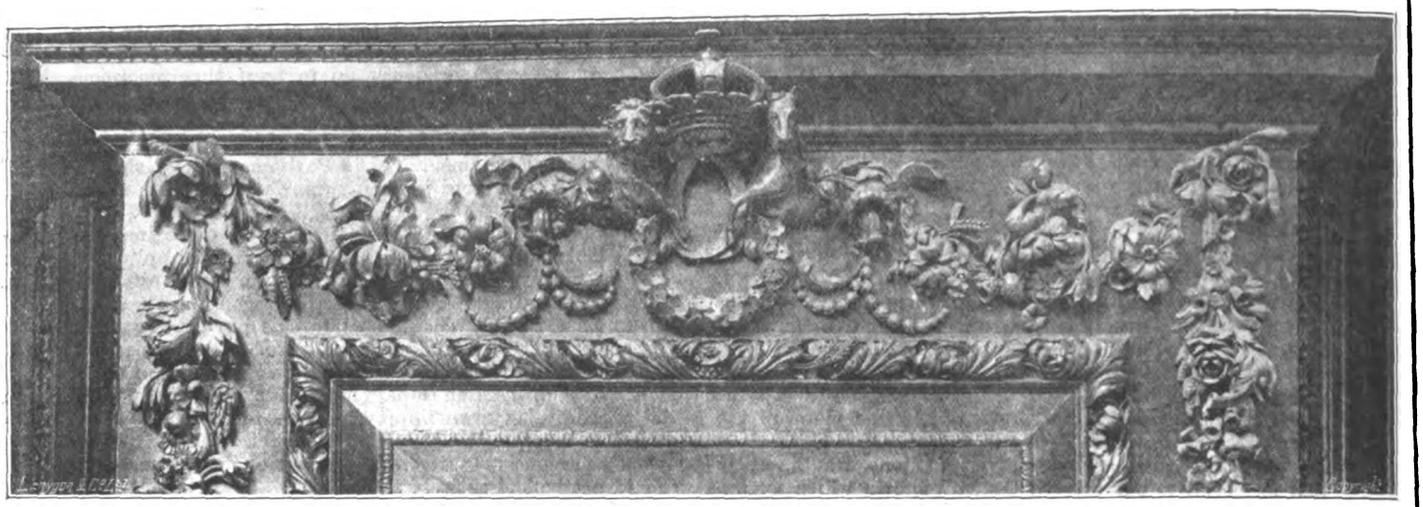
I have no doubt that much of what I have just read has occupied the mind of Mr. John Burns—the President of the Local Government Board—who has a very keen eye for the picturesque, useful, and healthy, and he has brought in a measure entitled "The Housing, Town Planning, &c., Bill," the object of which is, no doubt, to prevent as far as possible the loss of good opportunities, and to provide better housing for the working classes.

I am not concerned at the moment, bearing in mind the title of this paper, to consider so much in detail the provisions of the Bill as regards Clauses 10 and 11, but there can be little doubt that to leave to "four inhabitant householders" the power to put the ratepayers to the expense of a Local Government Board enquiry is very dangerous, and the power of the Board is supreme. Clause 14 respecting orders for demolition should, I think, be well looked into before being passed.

But even speaking as an architect, one can hardly allow to pass unnoticed that part of the Bill which gives so much freedom to local authorities to appropriate any land in their possession as a building site for dwellings for the working classes, including common land, or public parks, gardens, or other open spaces of which they may be custodians. This places in jeopardy many of those fine open spaces which have been acquired in recent years by beneficent bodies at great cost to the community generally, and to private individuals in particular, and which have done so much also to improve the surroundings of those open spaces, and to provide fair breathing areas for our over-crowded city. It is too dreadful to contemplate the possibility of portions of beautiful Hampstead Heath, for example, being appropriated for dwellings for the working classes, or, indeed, for those of any other classes. It may be said that it is quite improbable that any local authority would be so obtuse as to suggest the giving up of any favourite open space for either a bit of new town planning or a row of working-class dwellings; but one has to consider the power as we find it under Clauses 7 and 8 of the Bill of last year. It is true that Mr. Burns has consented to amend these clauses, but there are still remaining certain powers in the Bill which, if administered by a body caring more for a particular section of the community than for the whole, would certainly do more harm than good. It would, in my opinion, never do to trust these enormous powers for evil entirely in the hands of local authorities, and certainly not entirely in the hands of the Local Government Board, and I hope that before the Bill becomes law it will be found that to Parliament, and to Parliament alone, shall be entrusted the last word in the expropriation of open spaces in London.

Clause 4 of the Bill, sub-section (2), is quite inadmissible. This clause provides for the payment and application of any purchase money or compensation for lands, estate, or interest affected by the application of the Act. The Local Government Board's decision as to this payment, or compensation, is to be "final and conclusive, and shall be binding on all persons claiming to be interested in the purchase money or compensation so paid and applied." Surely if for the purpose of a town improvement or for the building of dwellings for the working-classes an open space or a piece of one's garden is required, the amount of the compensation should not be left entirely and without appeal in the hands of an individual to be appointed by the Board, whose views one can well imagine would not be entirely lost sight of in his award. There should, obviously, be left an opportunity on the part of the owner to be represented, and an independent umpire should be appointed.

Clause 45, sub-section (3), gives power to the Board to refuse to approve any town planning scheme except with such modifications, and subject to such conditions as they think fit to impose, and sub-section (6) of the same clause gives power to use the land taken for "providing open spaces, parks, pleasure or recreation grounds, or for the purpose of executing any work upon the land, whether in the nature of a building work or not, and the decision of the Local Government Board, whether any purpose is a building purpose or not, is again to be final."



The above two sub-sections require very careful consideration, as they give far too much power to the officials of the Board.

No doubt one of the intentions of the Bill is to provide for more healthy areas and dwellings, and for the better laying out of towns, but the whole of Clause 48, "Power to enforce the Schemes," is too drastic, and sub-section (3) of Clause 49 is a fair startler; because, if the operation of a scheme injuriously affects any property, but at the same time increases the value of certain other property, and compensation is paid, the whole or any part of any sums so paid may be recovered from the person whose property is so increased in value, and sub-section (4) again leaves the whole matter to the final and conclusive decision of the Board. All I can say is that the man who owns property in the vicinity of an improvement scheme has my commiseration, and, further, because under sub-section (5) "the money may be recovered summarily as a civil debt."

I am much afraid that the excellent ideas of Mr. Burns to give facilities for the prevention of planning blunders, and to secure the better architectural treatment of building areas, will not be taken advantage of so much as they might have been because of these drastic measures of expropriation and procedure being left for administration by officials of the Local Government Board, from whose final decisions there is to be no appeal. Many owners of coveted open spaces and gardens may live to congratulate, after all, our sister island by reason of the insertion of Clause 61, sub-section (2), "This Act shall not extend to Ireland." There is another clause in the Bill, viz., 55, sub-section (1), which defines "local authority"—so frequently referred to in the Bill—as "The London County Council." I think that the "local authority" should be the "local authority," and not the great central body whose work is already overwhelming, and whose knowledge of the needs and requirements of the real local authority cannot be so great as that of those living in the locality itself.

Amongst the bodies who are not neglectful of the great benefits which accrue to the general community of a city by reason of successful town planning architecturally treated the Royal Institute of British Architects may be mentioned. In February last Mr. H. V. Lanchester read a paper on "Town and Country: Some Aspects of Town Planning," full of artistic and thoughtful matter; but, like the schemes of many more of us, his were too ambitious and too costly for modern consideration. There was one feature, however, of his design for a main thoroughfare which deserves attention in all such schemes, and that was the provision of insets, or large recesses, in the line of street; and in the recesses he would plant shrubs, flowers and trees, and place

Digitized by Google

UPPER PART OF MANTELPIECE WITH CIPHER OF CHARLES II.—School of Grinling Gibbons.

seats, thus affording splendid opportunities for beautiful treatment and architectural successes from the returns or side elevations of the building more immediately fronting the avenues.

Town planning has not been altogether neglected by the great ground landlords of London. The Chelsea, Westminster, Bedford, and Ecclesiastical Commissioners' estates testify to many decided improvements in street outlays, and although the architectural treatment of some of them is not all one could desire, still, there is the good intention, and for that even one must be thankful. At the present moment there is a great scheme before us, initiated and to be paid for by the City Corporation—viz., a new bridge across the Thames between Southwark Bridge and Blackfriars, leading, too, to the southern front of St. Paul's Cathedral. Various objections have been already raised against it. I think I shall have many with me in the suggestion that this scheme would afford a fine opportunity for a competition amongst architects and engineers of England, and I hope these words may reach the ears of the City authorities. There are still splendid opportunities for improvements in London. Trafalgar Square, Piccadilly Circus, the continuation of Pall Mall westwards by a new street into the Green Park, a new street from Oxford Street opening up the British Museum, continuation of the Haymarket southwards by a new street into the Mall of St. James's Park, the formation of a quay or boulevard from Blackfriars Bridge right along past the Tower to Shadwell, and many other improvements suggest themselves.

The Brothers Adam also merit our warm thanks and admiration for what they have done in the Adelphi. The difficulties of level between the Strand and the Thames have been well surmounted by the arches under the streets, and Adelphi Terrace is still a beautiful feature of London. Not only is there a skilful piece of planning and construction in the Adelphi, but the brothers have created a style of architecture simple and good which even now has its many admirers and adherents. We might go further and fare worse as regards what is good and suitable for London.

The value of ground in London is so great that it is of little use calling up purely visionary schemes of town planning. Consideration must be given to the rights of ownership and to created interests, and all schemes which ignore those rights have little chance, I hope, of success. I am afraid that the great increase of traffic of London—a subject crying for remedial measures, one daily and hourly affecting our pockets and our tempers—can only be successfully provided for by bridges or by subways. We dare not hope to drive new streets through the heart of the City, or through the West-End; the disturbance of trade and business, and the terrific cost of expropriation make that idea entirely out of the question; but I see no reason why the Corporation, the London County Council, and Parliament should not seriously tackle this question of bridges and subways to relieve the worst of our congested thoroughfares; and again I suggest this as a fine opportunity for a competition amongst English architects and engineers.

We have still a glorious city wherein to dwell; it holds its own against all the cities of the world by its parks, its squares, and its open spaces. It contains the finest Protestant Renaissance cathedral in the world; its Abbey gives way to no other as an example of a Gothic ecclesiastical edifice; its historic buildings, museums, hospitals, and asylums command the respect and admiration of the world; and there is, above all, that grand old river—the sometime "silvery Thamis"—providing that healthy lung from which we all receive so much benefit; and, finally, there is that corner of Westminster Bridge from which the beautiful curve of the river is seen, embracing the best of river fronts—Somerset House, terminating in the prospect of the great cathedral—and from which also, turning round, there are the Houses of Parliament, Westminster Abbey, and all the other charming surroundings which we know so well.

We have the ability and the money to make these improvements a success; there is better architecture than there was fifty years ago, sounder construction, finer detail, and decidedly finer planning. Our street architecture meets more the needs of the commercial man and the shopkeeper, and if we ignore a little more than we do mere "arty-arty" productions, and give a little more simplicity to our work, clients, the public and architects generally will benefit. The architecture of our new streets shows a stronger desire, day by day, to rid itself of "rococo" embellishments and "stuck on" ornamental carving. Carving is a good servant but a bad master. In moderation it is quite an essential to a successful building, but if sculpture is to be employed (and I for one should like to see it much more employed) it should be confined to interiors in which properly designed provision is made for it. Its use in our exteriors—to rely upon recent examples—is a mistake; our atmosphere does not lend itself to it, and, even if it did, female figures apparently on the verge of slipping off pediments, and male figures in the act of falling from facades of buildings is not encouraging. The most recent examples of sculpture, as applied to architecture, have set back the clock, and have done considerable harm to one of the grandest of our arts. However, let us all hope for the best, and trust that fifty years hence London will be brilliantly the gainer by the incentive now given to good town planning, and to good architecture to adorn it.

We can, and must, make London even better than it is; we want it to be the safest, healthiest, most commodious, and most elegant metropolis in the world, and I conclude by echoing, as I have done before, the words of Voltaire, and say:—"May Heaven send some man, some statesman sufficiently zealous to undertake such projects, with a mind sufficiently firm and enlightened to carry them out; and that he may have trust enough reposed in him to make them a success."

NOTES ON BOOKS.

"The Decoration and Furniture of English Mansions during the Seventeenth and Eighteenth Centuries." By Francis Lenygon. (London: T. Werner Laurie. 31s. 6d. net.)

A COMPLETE treatment of the subject of this book would fill many large and weighty volumes, far too ponderous for anyone to read except the student who desired to become an expert in the restricted field of domestic art of which the author treats. It may be said, therefore, at the outset that the book before us is not a complete and exhaustive

Digitized by Google

MANTELPIECE, CIRCA 1770 A.D.

treatise on the subject. It is not such a *magnum opus* as a German professor would have spent his life in compiling, but within its limits it gives a very fair insight into the nature of the decoration and furniture of English mansions during the seventeenth and eighteenth centuries. It should be noted that the scope of the book is limited to two centuries of English domestic art and to the manifestations of that art in mansions, the homes of the wealthy. Hence the examples illustrated are sumptuous and costly. Moreover, they are for the most part taken from the very fine collection of Messrs. Lenygon at 31 Old Burlington Street, a fact that goes to indicate how very great is the wealth of England in magnificent craftsmanship. If one collection, that of Messrs. Lenygon, can furnish some two hundred fine examples as a selection only of the objects it comprises, and even then does not include such minor objects as table glass, fire screens, or indeed anything that is not strictly decoration or furniture of a mansion as distinguished from personal effects, it needs no argument to show that any attempt to completely cover the ground touched upon by this volume is stupendous. Hence we take Mr. Lenygon's book as it is and find it an admirable epitome of the subject with which it deals. The scheme of the book is excellent. A number of short and concise chapters on the various epochs of decorative domestic art in the seventeenth and eighteenth centuries and the crafts concerned give tersely and succinctly the main features of the subject and the influences that affected its development. Thus, the influence of the Flemish and Dutch work on that of England in the time of Wren is clearly pointed out, and the part played by Kent and his patron, Lord Burlington, in substituting Classic Roman and Italian Renaissance precedents as a basis for our own designs is well elucidated. Then the next great change, brought about by the Brothers Adam, is explained, and also the wave of French influence united with the "Chinese taste" that succeeded. By the courtesy of Messrs. Lenygon & Co., Ltd., we are permitted to reproduce some of the illustrations in this volume.

In the Buralem Municipal Buildings Competition, Mr. H. T. Hare, F.R.I.B.A., has just been appointed assessor. Designs have been received from twenty-three architects. The author of the design placed first will carry out the work; the authors placed second and third will receive premiums of 100*l.* and 50*l.* respectively.

LATE SEVENTEENTH-CENTURY ENGLISH CHAIR.

EARLY SEVENTEENTH-CENTURY ENGLISH CHAIR.

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *Arkitektur og Dekorativ Kunst* has given us the result of the competition for the new Bourse at Christiania, with illustrations of the first premiated design by Carl Michalsen of Christiania, and of the second premiated design by F. Rahn of Stockholm. The design by H. Bull is also illustrated. Both this and the first premiated design use Greek Doric porticos to a severe and simple general treatment. Almost barbaric in its somewhat affected simplicity is the crematorium in the old cemetery of Christiania, erected from the designs of Oscar Hoff for the Norsk Likbraendingsforenings.

Der Architekt illustrates additions to the Hotel Wiesler at Graz, of which Marcel Kammerer is the architect; a new bank at Prague for the Wiener Bankverein, by the joint architects J. Zasche of Prague, and Alexander Neumann of Vienna; and the new premises of the Prager Eisenindustrie-Gesellschaft at Prague, of which also Herr J. Zasche is the architect. These are all "new art," but in the last-mentioned example there is sufficient play of fancy to remove the design from the region of barbaric simplicity that is the latest phase of the movement. Quite different and more satisfactory are two designs for a new ball-room at the Italian Embassy in Vienna, by Pietro Palumbo, in which more conventional detail is handled with sufficient originality.

Deutsche Bauzeitung concludes its account with further illustrations of the competition for the new police buildings on the Augustiner site at Munich.

Architekten-und-Baumeister Zeitung illustrates a design by Jacob Modern, architect, for an imposing piece of street architecture comprising shops and flats in Nussdorfer Strasse, Vienna, in which for once "new art" does not figure, but a picturesque and effective rendering of Renaissance motifs quite sufficiently modern in treatment to escape any charge of being archæological.

NOTABILIA.

THE *Burlington Magazine* for this month contains a carefully written article on Philippe de Bourgogne (Felipe Vigarny), by Paul Lafond, with several admirable photographic illustrations of the wonderful work of that great sculptor and architect in the cathedral of Burgos, in which is exemplified both the latest influence of the Flemish-Burgundian school and some of the earliest Renaissance work in Spain.

The Art Journal.—Architects sometimes indulge in etching, as witness, not to mention well-known instances, an example in the current number of the *Art Journal* by W. Hilton Nash, F.R.I.B.A., and therefore the appreciative notice, with illustrations, of Mr. Muirhead Bone's work is of interest. An article containing much truth and real criticism is "The Treatment of Drapery in Painting," by A. L. Baldry. Mr. R. Ll. B. Rathbone continues his series on "The Artistic Training of a Jeweller," and has now reached the subject of the use of twisted and plaited wires. "A Distinguished Woman Sculptor" is an account of the work of Mary Pownall (Mrs. Alfred Bromet), which as illustrated is, if somewhat theatrical, at any rate delineative of character.

Pearson's Magazine in "The Mysterious Mummy," by G. St. Russell, has much information of solid archæological value on the subject of Egyptian mummies and burial customs, cleverly devoid of heaviness, and conveying real instruction in a popular manner, lightly enlightening.

GENERAL.

The Hermione Lectures at Alexandra College, Dublin, are to be delivered this year by Sir W. B. Richmond, R.A. A special course of lectures will be given at the college by Miss S. H. Harrison, entitled "How to Look at Works of Art."

The Late Mr. James Medland Taylor, of Rusholme, Manchester, architect, an ex-president of the Manchester Architectural Association and of the Manchester Society of Architects, and son of Mr. Isaac Taylor, of Stanford Rivers, Essex, left 86,163*l.* gross and 84,047*l.* net.

It is Officially Announced that it is the intention of the Academy—all rumours to the contrary notwithstanding—to hold next winter an Exhibition of Works by Old Masters and Deceased British Artists, and they trust that the owners of such works will kindly lend them with the same liberality as in the past.

FORTHCOMING EVENTS.

Saturday, August 14.

Manchester Society of Architects: Visit to "Tirley Court," Cheshire (a residence by Mr. C. E. Mallows).

Tuesday, August 17.

Manchester Society of Architects: Visit to Middleton.

Saturday, August 28.

Architectural Association: Camera and Sketching Club, Visit to Hayes, Harmondsworth, and Harlington.

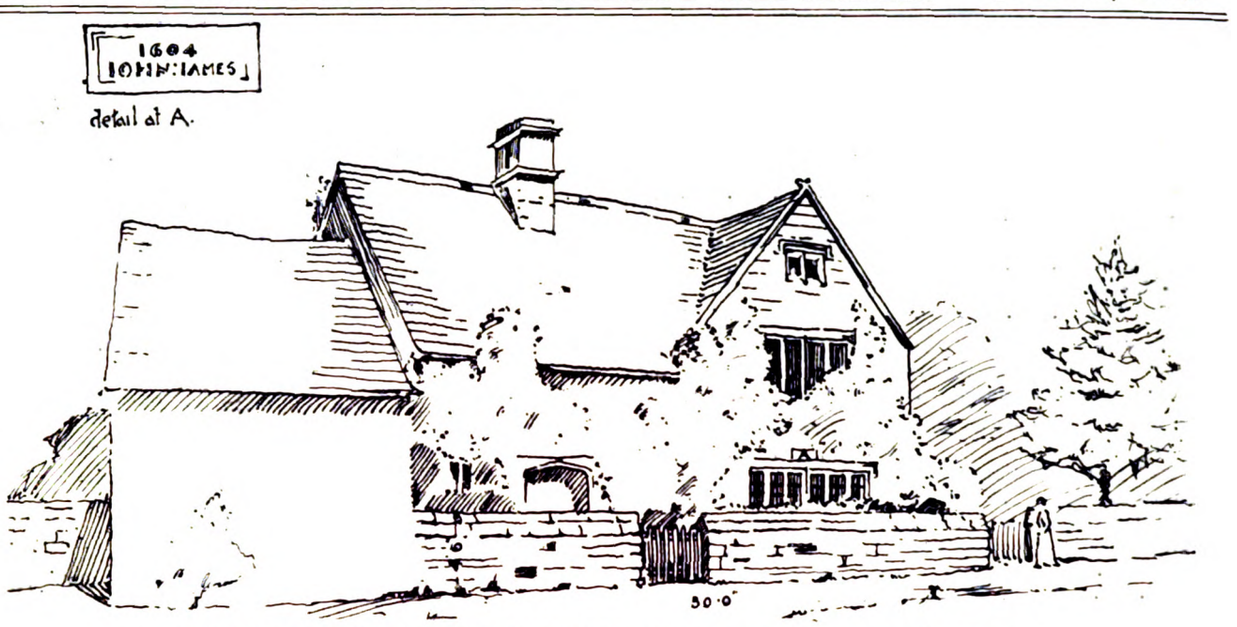
Saturday, September 11.

Society of Architects: Students' Sketching Party.
Architectural Association: Camera and Sketching Club, Visit to Guildford and district.

THE A.A. EXCURSION—CHELTENHAM.

HAVING reached the fortieth of its series of annual excursions, of which all but very few have been in England, the Architectural Association now perforce finds itself obliged to visit again centres that have formed its base on previous occasions. After a lapse of fourteen years it is hardly too soon once more to make Cheltenham the headquarters for the study of the architecture of Gloucestershire, and particularly of the Cotswold district. As usual, the members of the party gathered in twos and threes on last Saturday and Sunday, renewing the acquaintances and friendships that are so marked and happy a feature of the annual excursions of the Architectural Association. From all parts of England and Ireland come architects to study together for a week, and although there are several who have been present on many occasions, some, of course, for various reasons drop out, but there is always a ready accession of younger men to fill the gaps, and the popularity of the A.A. excursion seems never to diminish. After a quiet Sunday in Cheltenham the party commenced the serious work of the week on

Monday, when in glorious warm and sunshiny weather carriages from Cheltenham were taken for a drive through beautiful scenery to Whittington, where the Court and Church were visited. Whittington Court is a typical Gloucestershire stone country-house of the seventeenth century, with picturesque farm buildings that looked their best in the bright sunshine seen across the duck-pond. Picturesque as is the house with its three gables and porch on the entrance front, it is the interior that contains the most tit-bits of interest, chief of which is the charming newel stair, with good handrail and balusters and an original dog-gate. The newels have clearly originally been continuous from landing to landing, as was the custom in early examples, but have at some time been deprived of the probably turned shaft that ran from the square newel to the soffite of the flight above. A charming feature sometimes, but not often, found in English houses, though common in France, is to be seen at Whittington Court, internal porches to bedrooms, or *tambours*, as they are called across the Channel. At Whittington there is one with very charming detail if somewhat unorthodox. There are several mantelpieces and panellings of interest in the house, not all of the same date, but picturesque and quaint if somewhat coarse in detail, as seventeenth century work is wont to be.



The Church at Whittington is small and, as it stands, though evidently altered, of curious plan. A narrow nave and chancel, with a "processional aisle" on the south side of nave leading to a fair-sized side chapel, is quite unusual. The aisle was certainly wider in Norman times. There are three stone effigies, two of knights and one of a dame in the church, probably of thirteenth century date, and in the chancel wall is a fragment of a triple panel bearing the same arms as those on the knights' shields. On the north side of the nave is a wall arch that probably formed the recess for a founder's tomb.

Leaving Whittington the excursionists proceeded to Charlton Abbots, where the manor-house is another example of the seventeenth century, again with the typical three gables on the principal front. These, with good chimneys, the three storeys in height, and the position of the house on the hill-side, all go to make a highly picturesque composition. Of like nature here also are the farm buildings, charming, though probably unstudied in their grouping. The most interesting feature within the house is the stair, with solid oak treads around a walled enclosure, if not solid wall, 5 feet 4 inches by 5 feet 6 inches. A room with segmental barrel ceiling, some good door frames and panelling, and a carved mantelpiece suggest that the interior was once much more remarkable than it is to-day.

On their way back to Cheltenham from Charlton Abbots the party stopped for a couple of hours or so at Sevenhampton, visiting first the small but curious church, very narrow and very long for its size, with a central tower and transepts said to have been added in the time of John Camber, whose brass records that he died in 1497. The transepts being wider than the nave and tower has necessitated the use of quaint internal flying buttresses, to meet the thrust of the arches and vaulting of the tower. The window of the south transept is very peculiar. Clearly contemporary with the erection of this part of the church, it presents a late fifteenth century attempt to reproduce the form of an early thirteenth century window from memory rather than from measurement. Most of the work done in the fifteenth century, and there is much of it, is quite good though small. This church is one of the many in which the axis of the chancel inclines to the north from that of the nave. The chancel originally was of very early thirteenth century, or possibly late twelfth century date, whilst a Norman lintel over the south door suggests that part of the church may have been earlier still, a suggestion strengthened by a blocked-up semicircular headed arch in the north wall of the nave.

Sevenhampton manor-house, mainly seventeenth century, has been much altered at various dates, and though still picturesque palls a little after Whittington and Charlton Abbots. There are some pieces of old seventeenth century woodwork inside the house, but the main interest of the excursionists was directed to the trophies of big game-shooting and treasures of foreign travel collected by the present tenant, Captain Bears, who received and entertained the party.

THE POST OFFICE, STANTON, GLOUCESTER. From a Sketch by Banister Fletcher.

Tuesday was devoted to Broadway, the gem of the Cotswolds, and the delightful old market town of Chipping Campden. To economise time and avoid a long drive, the train was taken to Broadway, on reaching which the church was first visited.

The church of St. Eadburgh is a cruciform building with central tower and aisles to the Transitional nave. With the exception of the south transept, the windows are insertions of the fifteenth century, and contain some fragments of old glass. Naturally there has been much modern alteration in the fittings of the church, and an old but not remarkable Perpendicular relic of a pulpit has been repaired and painted crudely and substituted for a fine Jacobean pulpit and sounding-board. There are some remains of old screens, now made up and used for choir stalls, and a Jacobean communion table and rail with a made-up reredos of old panelling.

After a long and hot walk in the blazing sunshine from Broadway village to the old church and back it was refreshing to be in the cool of Abbot's Grange, where the party was received by Mr. Frank D. Millet, the present occupant, who, with the exception of adding a studio, is preserving the features of the old house. The hall with its open roof, the solar with a peep-hole overlooking it, and the abbot's chamber and chapel are all in excellent preservation, and a typical fourteenth-century grange is presented. Very interesting is the collection of bric-à-brac that Mr. Millet has made and has used for the furnishing of the old house. Of course, it is not contemporary, but even seventeenth-century furniture and oddments do not look quite out of place in a mediæval house. After luncheon at the Lyson Arms, which, in the increased popularity of Broadway, has lost much of its old charm and taken on the character rather of a Wardour Street old-furniture emporium, the party visited two of the old houses in the village—Orchard Farm, now occupied by Mr. Robert S. Hichens, and to which Mr. Andrew Prentice has added a charming music-room; and the Court Farm, now the residence of Madame Navarro (Miss Mary Anderson), which also has been altered and enlarged so that two cottages are now joined by a new hall and form a good-sized country house. These two houses, with much old furniture and fittings, some original and some imported, formed an object-lesson in the science of turning cottages into fair-sized houses and making these liveable modern homes while retaining much of their old-world charm.

Leaving Broadway, which, by-the-by, is in Worcestershire, here dovetailed into Gloucestershire, the party drove, with some walking, up the slope of the Cotswolds to Chipping Campden.

(To be continued.)

NOTES AND COMMENTS.

The criticism of Mr. Edwin T. Hall, F.R.I.B.A., on the provisions of the Finance Bill as affecting the estate of Dulwich College, has probably assisted, if it has not wholly originated, the proposal of the Government to amend Clause 11 so as to grant exemption "on the site value of any land where it is shown to the Commissioners that the land is being kept free of buildings in pursuance of any definite scheme, whether framed before or after the passing of this Act, for the development of the area of which the land forms part, and that it is reasonably necessary in the interests of the public, or in view of the character of the surroundings or neighbourhood, that the land should be so kept free from buildings." Of some assistance to building estates that are waiting for builders will be the proposed exemption of land on which the owner or his predecessors in title have spent 100*l.* per acre or more for the purpose of developing the land, although at the time it may not be built upon or used for any business, trade, or industry other than agriculture.

A faculty has been granted for the demolition of Holy Trinity Church, Kingsway, which fell into a dangerous condition, it is alleged, in consequence of construction of the tube railway and other excavations. There seems to be little doubt that despite all the care that the engineers give to the construction of tube railways, such borings through the ground do affect the soil beneath buildings in the vicinity, and lead to settlements that upon occasion may be dangerous to the stability of such buildings.

We are pleased to note that Birmingham is not to be found lagging far behind other provincial cities, but is to have its own Day School of Architecture at the Municipal School of Art. The course is to be one of four or five years and we have no doubt will be found to be as efficient as those already established in Liverpool, Manchester, and other centres. One great advantage that Birmingham possesses is the availability of the magnificently equipped testing laboratories of her University, where architectural students may expect to be able to participate in the instruction in those branches of architectural knowledge that touch closely on the study of engineering.

Whilst it is easy for medical officers of health to strain their powers and inflict injustice, it must be admitted that in the matter of the public health some control over the speculating builder is necessary, and a recent inquiry by the Local Government Board into the condition of affairs at Enfield, in the county of Middlesex, emphasises this point. Absorbent bricks, absent or defec-

Digitized by Google

tive damp courses, leaking roofs, insufficient air space and light are characteristic of many of the low-grade tenements, cheap and nasty, which conjoined with cheap travelling facilities have degraded Enfield in many parts from a charming residential suburb almost to the level of a London slum.

Wroxeter, the Roman city of Uriconium, about twice the size of Silchester, the excavation of which latter has added much to our knowledge of Roman life in Britain, has been unduly neglected and with the willingness of Lord Barnard, the freeholder, and the eagerness of Salopians to furnish funds, it seems a pity that the best of our experts in Roman archæology cannot at once turn their attention to Wroxeter. Sarum and Verulamium no doubt have claims, but we have vivid recollections of the remarkable interest of what has already been excavated of Uriconium, and should be glad to hear that further work there is to be immediately undertaken.

The decoration of our public buildings with painting and sculpture is eminently desirable, and what has been done at Plumstead should be an incentive to other localities. Not only is the alliance of the arts necessary to the full fruition of architecture, but pictures are, or may be, undoubtedly in the present day of high didactic value.

ARCHITECTURE: ITS TRUE PRINCIPLES.—XVI.

By R. OWEN ALLSOP.

Ratio and Proportion.

THE term "proportion" is somewhat loosely employed in ordinary discussion on architectural matters. More strictly the meaning intended to be conveyed is *ratio*. Thus the ratio of a capital to its columnar shaft may be 1 to 10, or $\frac{\text{capital}}{\text{column}} = \frac{1}{10}$. The term proportion—in the sense of the geometer—requires a third term. What is *meant* to be conveyed by the colloquial expression "proportion" is sufficiently understood, but it would be as well to reserve the term to define the identity or similitude of ratios, and to say that the relation of one part to another of that which has two parts is in such and such a ratio.

Much has been said in writing on the subject of architectural proportion of "subtlety." Now subtlety is not a pleasant word. It does not suggest simple straightforwardness. Possibly *refinement* is intended by those who employ the term. If so, we are at one with the opinion that there should be refinement in proportioning, since this suggests high reasoning and the impress of mind upon matter which is the essence of a creative art.

We favour distinct and definite ratios. So long as the architect has divided rule and compass and the examples of the refined Greek designers, let proportion (or ratio) be simple; let us get rid of surds. The eye does not like to be perplexed. The process savours too much of deception. It is one of the benefits of brick building that it encourages pure and simple ratios in the division of parts.

The geometrical basis of architectural design, the prime three dimension figures—circle, square, triangle, sphere, tetrahedron, and others—suggest simple ratios in proportioning other concrete figures. The inorganic nature of a building—as distinct from forms of animal and plant life—claims kinsmanship with the crystal as a natural method of bringing geometrical order and design out of the primeval order of sublimity.

It is well that the architect, dealing with inert matter, should work rigidly to some definite scale. It does not matter what that scale be—feet, metres or modules. The essential part is the mathematical division into exactly equivalent parts. To design exactly to scale and to proportion to simple ratios, is a becoming act of humility, as graceful in effect as the idea of rising above mathematical scale and proportion is offensive. Let us recognise our limits. Sublimity is a scale of infinity; our finite works must be to the measure of the finite. Finite order is regularity, and regularity is order. Irresponsible proportioning, guess work, hazarding are disorder. We deal with bricks and mortar—and a percentage. The gods may proportion on a scale we may designate elastic, but whilst man measures the earth and passes along like the hands of a clock it is necessary that his mind advances by equal step-by-step measure in design.

The larger the part the greater the simplicity, should be the guiding rule in architecture, and those inclined to complex involved proportion—materialised "surds"—may remember the Greek architect and his double-square temple cell. Simple ratios please both the eye and the mind; the former because it dislikes involution, and the latter because it recognises the bowing to superior forces—law. We may reasonably leave the idea of infinitely elastic proportions to the oyster in his "parasitically sublime" shell and put ourselves in the yoke of geometry with its squares and circles and elementary basic forms. Time is created as an entity by scoring divisions, of equal value, upon eternity. Minutes and seconds are aliquot parts of the hour. They are there in a proportionate relation. The essence of order is regularity of arrangement, and all beautiful things are based on order, mundane and geometrical, or, if extra-mundane, on the order of sublimity, which we need not pretend to comprehend.

If any part is a multiple of a whole we may say it is proportionate thereto. Unless this is so there is no true ratio, or at any rate a less noble one because less simple, less truly a ratio, and hence less affinity to actual truth itself. If there exists no reason why a certain height, width or depth should not be a simple ratio and refer in simple terms to a given unit of measurement, it is æsthetically more satisfactory that this should be so, just as it is constructionally better that a measure, space or length, should be part or number of the basic scale, whether this latter be feet, metres or modules. In this matter the architect is bound in fetters (and rightly so) where the painter and sculptor, copying that which is based on a Divine system of order (termed sublime), are in a sense more free. It is well that the architect should of necessity be compelled to tread out his spaces with manacled feet. It suggests a state of being under rule, a state of order, of bowing to a superior force.

Whatever the talk about proportion we know in practice it is a matter largely based on the pencil point and the graduations of the scale—the unit of measurement—the true "module" of design, whether half a column's diameter or not does not concern the question. The circle arises from the revolution of the compass point, the sphere is born of the circle, the cube of the square, the tetrahedron of the equilateral triangle. Why, then, when the change is made to less simple and hence less noble figures—superficies or solids—should we wish to cast off the mathematical tether? The architect must be a geometrician and a practical mathematician. All the finer effects are based on these exact sciences. There is no more reasonable course than to be bound in all important ratios by a geometrical spirit, leaving the freer hand to less significant details.

The preceding remarks may be understood to apply to large divisions. Recognised examples support the suggested principle. In smaller affairs the question of what we generally understand by the term "proportioning" may assume a different aspect, and any contrast of varied dimension to regular division (monotony) seems allowable. The designer has a freer hand, and his skill will be a measure of his study of nature and natural objects of beauty; for it cannot be allowed that the art of proportioning is to be learned from the study of architecture solely. It is a question of eye education. To confine the attention to architectural form leads to those strange theories of triangulation that are naturally repugnant to the sentiments of the artist. If anything at all is to be learned from these theories it is that in large parts all true architecture shows a tendency to simple and direct ratio, a fact that might be demonstrated better by plain, figured dimensions than by mysterious circles and

Digitized by Google

triangles that cause misapprehension in the mind of the young student. And it must be considered that not so much virtue exists in dimensions of so many cubits width, breadth and height, as that the command is given and obeyed:—*Thus, shalt thou make it.* Decision and definiteness at the beginning of things is indicated, with power, authority and pre-arrangement; as when, while others vacillate, someone draws a line from city to city, and says "Make the railway *so.*" Tables of stone control matters of life and death only. What the simple geometrical mass formation is to composition, so may be assumed to be the law of simple ratio in large parts.

One cannot withhold the thought that too much mental agitation is exhibited over the matter of proportioning in architecture, and that the acrimony of discussion suggests *de facto* the absence of the proportioning sense; and, further, that the elevational instinct, that lies like a curse over much modern architectural design, is responsible for the creation of a stumbling-block. Those who never first conceive a design in the solid, but originate solely with board and square, are necessarily much concerned over relative widths and heights. So also is the composer of pictorial advertisements and the fretworker, and all artists in one plane. Yet we rarely feel called on to criticise the results of geometrical length and breadth in the actual building. If the Bell Harry Tower at Canterbury is seen in evening gloom we perhaps may be drawn to make comparison as to its relative height and breadth; but even here the effect is rarely that of elevation purely, two sides being mostly seen. And if we behold such a view as that in fig. 38, we doubt if any ever may be induced to institute an inquisition as to the arithmetical ratios in the minarets, being solely impressed with the fact of a slender, elegant proportioning. Many of the fine theories of proportioning would doubtless have been seen to have been superfluous had it been realised how widely the ratios vary even in examples of Doric columns, *all* beautiful and majestic.

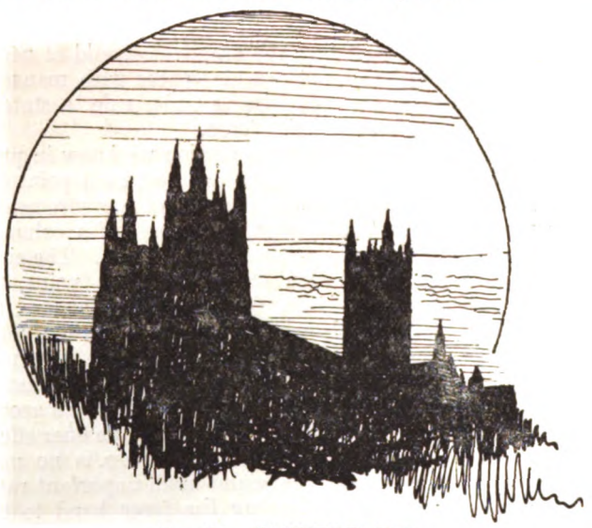

Fig. 37.—CANTERBURY.

If we diverge in proportion from the primal cube the *effect* can only be by extension in height or width; hence, by a comparative analogy, we are never concerned as to the arithmetical proportions of a man, but say that he is *tall* or *short*. The majesty of tall proportion has always been recognised, but in architecture there is also effect by lateral extension. The long nave and lofty tower mutually enhance one another.

That which we intend when we talk about proportioning in architecture, as a root principle, must be adjudged to be not elemental, but compound; that is to say we might reasonably use the title, "The Proportioning of Architecture," in place of a treatise on "Architectural Design." The act of proportioning, rightly understood, includes all principles, or a large number of such. The elevationist does not understand this; nevertheless, it will be seen that when we proportion (in three dimensions) we bring into consideration contrast, gradation, grouping or massing, concentration and climax, and many other qualities. All effects of lineal or superficial proportioning are modified in perspective (true) effect. Naturally, in elevation making we are greatly concerned with proportioning—not a line can be drawn without involving the principle; hence, even in the matter of two dimension design "proportion" is an all-embracing term.

In practical designing, proportion, where not ruled by the prime architectural consideration of fitness for duty, is a matter of beautifully contrasted and varied dimensions, and the opposite is monotonous division—indeed it might be said that this latter is the *foil*, enhancing variation much as perhaps the equal interval and

Fig. 38.—SANTA SOPHIA.

regular beat of the bar in music may be considered a foil or the relieving background to the variation in time-interval and rhythm of the air. There is a wonderful relation between regular (monotonous) motion and music, which may be observed to add a peculiar dignity and majesty to even mechanical motion—where regular—and doubtless herein is the origin of the idea conceived by primitive astronomers as to the music of the heavenly spheres. It may be that the magical effect of the introduction of brick and stone course lines into an elevation is the foil of monotony to the variation of proportional dimensioning. The subject of proportion in architecture is one behoving all to treat upon with due caution and consideration for other's opinions; but it may be laid down that to educate the eye—as the window of the mind—by the study of natural objects of beauty is the only way to acquire the art of what we call "proportioning," and of which the essence is beautiful and interesting contrast of dimensions and sizes. The study can only be by analogy, since nature refuses to be—cannot be—copied, but may be the source of inspiration arising from deductive reasoning. In this manner the field from which to glean ideas becomes inexhaustible, and even if actually-found, natural dimension be literally copied, there is such a fund of these that the whole art world during the life history of our globe would no more exhaust the fount than a thimble remove the waters of the ocean. Thus, the study of the stratification lines in a piece of coal may be more to the purpose than any micrometrical measurement of old Grecian colonnades. As there are more obviously beautiful things than coal, the supply of naturally beautiful dimensions may be said to altogether exceed the demand.

(To be continued).

Mr. William Owen, architect, of Duchy Chambers, Clarence Street, Manchester, died last week. Mr. Owen, who was born in Altrincham in 1852, studied at the Manchester School of Arts, and in 1874 was awarded a gold medal by South Kensington for the best architectural design of the year. He was afterwards elected an Associate of the Royal Institute of British Architects, and he has since carried on an important practice in Manchester and district.

PORTLAND CEMENT.

THE manufacture of Portland cement has made such remarkable strides within the last few years, as regards the quality of the product turned out by our modern factories, that the standard books of the quite recent past are hopelessly out of date, not only as regards the methods and processes by which Portland cement is now made, but also with respect to the qualifications that should be expected of even the average grade of present-day cement, let alone the finest or special classes of the material. Hence we welcome the second edition of an up-to-date, comprehensive, and scholarly book,* which in its revised and enlarged form may be taken as a synopsis of the latest knowledge and experience in the manufacture and in the testing of Portland cement.

The primary great factor in the superiority of our present-day cement over that of even a few years ago has been the adoption by English manufacturers of the rotary kiln, and it seems that in the near future this type is likely to supersede all others. It is remarkable that although a patent was taken out in 1877 by T. R. CRAMPTON, another in 1885 by F. RANSOME, and a third by F. W. STOKES in 1888, for rotary kilns for "the burning of Portland and other such-like cement," none of these early forerunners of the modern kiln proved a commercial success, the chief cause of failure being the absence of a suitable method of firing. It was not till HURRY and SEAMAN in 1898, followed by other American manufacturers, introduced the method of firing by means of powdered coal that the rotary kiln became a successful apparatus for the burning of Portland cement. Since this improvement numerous and careful experiments have determined the most suitable kind of coal, the amount of air, and the position of the delivery jet, and brought the rotary kiln to its present position of excellence. The form and detail of the rotary kiln is fully explained by the author, as well as those of the leading types of kiln that it is superseding.

It is now tolerably common knowledge that the constituents of Portland cement are lime, silica, and alumina in fairly well determined proportions, and that it does not much matter what limestone and what clay are adopted as the raw material, whether the white or grey chalk and alluvial mud of the Thames and Medway, the marl deposits of the Cambridgeshire district, the Lias formation of limestone and shale in Rugby and South Wales, the argillaceous limestone of the Lehigh Valley in the United States, or of the septaria of the London clay, formerly used for Roman and kindred cements. Corrections of these natural materials, of course, require to be made, an addition of clay in one case, an addition of limestone in another.

The natural materials will always be found to contain other substances besides lime, alumina, and silica, so that the theoretically perfectly pure Portland cement—a compound silicate and aluminate of calcium—is, as far as we know at present, unattainable, but it has always been a puzzle to us that magnesia should apparently be so detrimental to the quality of Portland cement when a large percentage in conjunction with lime, as in the case of some American limestones, produces a remarkably fine hydraulic mortar that can even be used with sea-sand, or, as in the case of the magnesite cements that have recently made possible a new industry, it seems to have valuable cementitious properties of its own. Mr. DAVIS says in respect of magnesia as a constituent of Portland cement, "the exact chemical action has not yet been definitely explained," and this, we must take it, is the extent of our knowledge to-day on the point.

After the rotary kiln the most important element in the improvement of our modern Portland cement has probably been the increase of the degree of fineness to which the product of the kilns is now ground. Many text-books on materials and some architects' specifications still contain the proviso that the cement shall pass 90 per cent. through a sieve of 2,500 meshes per square inch. It is a remarkable step from this to the requirement of the British Standard Specification that the residue on a sieve of 5,776 meshes per square inch shall not exceed 3 per cent. The British Standard Specification has indeed been a great boon to both the manufacturer and the user of Portland cement, not that we think it is perfect and incapable of improvement, but it gives the manufacturer a goal at which to aim and the user a standard of quality with which he should be content. It has also undoubtedly done more than anything else to bring before architects and engineers the high quality of cement that our English manufacturers are now prepared to give us. The improvements in grinding machinery that have done much to render possible this high quality—the ball mill, the tube mill, the "Griffin," the "Edison," and the "Kominor"—are described by the author.

Important to the manufacturer as are the details of selecting and mixing the raw material, burning, and grinding, which Mr. DAVIS, himself a practical manufacturer, describes, it is rather in the second part of his book that most of our readers will find the information that is to them particularly useful and interesting. The mineralogy of Portland cement is vital to the expert who is studying to find out why this useful product has its peculiar properties, and how they may be obtained and improved; but to the architect, the engineer, and the builder the sampling, testing, and uses of the material are of greater moment. Hence we are gratified to find that Mr. DAVIS has gone very fully into this part of his subject, and has given us a valuable account of the mistakes in the employment of cement that may frustrate the improved scientific accuracy and careful methods of our modern high-class manufacturers. The causes of surface cracks, efflorescence, discoloration, "dusting" of floors, shrinkage, temperature cracks, porosity and permeability of concrete, are all lucidly and fully explained. The methods and varied forms of apparatus for testing cement are dealt with at length in respect of fineness, weight, setting, soundness, contraction and expansion, tensile, compressive and transverse strength.

The important question of soundness, with its not necessarily connected phenomenon of expansion and the elements that influence the results of tests for this quality, are thoroughly treated, and particularly the position occupied by the Le Chatelier method, as to which the author's conclusion is that this is a test purely for expansion and not for soundness. Moreover expansion does not necessarily connote unsoundness, nor does the former always accompany the latter, but absence of expansion is a desirable quality in a cement, and this the Le Chatelier test does accurately determine. Other tests for soundness are considered—boiling, steaming, warm water, cold plunge.

With regard to tensile strength, our author strongly urges the adoption of tests with sand rather than with neat cement, both as giving a better indication of the full value of the cement in practice and as tending to reduce the considerable variations that slight differences of the conditions produce in testing briquettes of neat cement. It scarcely needs pointing out that for true comparison carefully tested standard sand must be used, as the results from the use of different sands with the same cement differ widely.

A useful section of the book is that on the ageing of cements and concretes, and the effect of this ageing on strengths, for information as to which, as Mr. DAVIS points out, we have to turn to America, Germany, or France. As an appendix are given the British standard specification for Portland cement, the American standard specification, the German standard specification of Portland cement used in the Prussian Government works, and the French Government specification for Portland cement.

Thus for the manufacturer and the consumer of Portland cement we have a standard work invaluable in every particular to each and all.

* *Portland Cement.* By A. C. Davis, Fellow of the Chemical Society, Associate of the Institute of Civil Engineers, Member of the Society of Chemical Industry, &c. (London: Woodford, Fawcett & Co. 15*s.*)

ANCIENT MONUMENTS OF SCOTLAND.

THE Royal Commission on the Ancient and Historical Monuments and Constructions of Scotland have issued in Blue-book form as their first report an inventory of monuments and constructions in the county of Berwick. The Commissioners state that they have been "appointed to make an inventory of the ancient and historical monuments and constructions connected with or illustrative of the contemporary culture, civilisation, and conditions of life of the people in Scotland from the earliest times to the year 1707, and to specify those which seem most worthy of preservation.

"The monuments in the county of Berwick have been visited, and a complete inventory, showing the situation and characteristics of each, along with a bibliography, a reference to the Ordnance Survey sheet (6 inch scale) on which it is noted, and the date on which it was visited, has been compiled and is annexed to this report. Your Commissioners consider that to render the inventory of practical utility these details are essential. The number of objects noticed is 260, of which 70, it is believed, have not previously been described. Your Commissioners propose in the current year to review the monuments in the county of Sutherland, and also, if possible, those in the county of Caithness, and lists have been distributed and other preparations made with that object.

"The fact that the Corporation of Edinburgh have recently caused to be compiled and have published an inventory of the older structures in the central part of the Old Town is an encouraging action that merits record. In course of the year various cases in which interesting monuments were threatened with injury or destruction have been brought informally to the notice of your Commissioners, and it is gratifying to record that representations made by your Commissioners have met with consideration from proprietors and others interested.

"Your Commissioners desire to make grateful acknowledgment of the manner in which the work has been facilitated by the clergy and schoolmasters of Berwickshire. Special thanks are due also to the Society of Antiquaries of Scotland."

Ecclesiastical Structures.

Under this heading it may be observed that there are remains of four monastic establishments:—

(1) The Abbey of Dryburgh, in the parish of Mertoun. Though much ruined, it is distinguished by the fine transitional and first pointed details, and for the considerable remains of the conventual buildings.

(2) The Priory of Coldingham, in the parish of that name, the successor of a much earlier foundation mentioned in Bede's *Ecclesiastical History*. A portion of the church alone survives, a transitional building showing detail of great beauty.

(3) Of the Convent of Cistercian Nuns at Eccles only a mere fragment, of Norman and transitional style, is left.

(4) The Priory of St. Bothan at Abbey St. Bathans, represented by the east wall and by a portion of the north wall of the existing church, and also by the recumbent figure of a prioress lying therein.

There are remains of Norman churches in other parts of the county, at Bunkle, Chirnside, Edrom, Legerwood, and St. Helens (Cockburnspath). Among ecclesiastical structures of later date, the most worthy of note are Ladykirk, said to have been built in 1500, and a perfect specimen of Scottish church architecture of that period, pointed barrel vaults of stone being used throughout; Cockburnspath, remarkable on account of the unique feature it possesses in the round tower rising in the middle of the western wall and having its upper portion pierced with cruciform loopholes of a somewhat military character; Greenlaw Church, noted for a fine square tower with vaulted basement and corbelled-out parapet, also suggestive of a keep; and the church of Lauder, bearing the date 1673, and a good specimen of the debased Gothic of the seventeenth century.

Castellated and Domestic Remains.

These, though numerous, are mostly unimportant. Cranshaws is the only keep still in its original condition standing alone and inhabited. Others, as at Duns Castle (Duns parish), Cowdenknowes (Earlston parish), Bemersyde (Mertoun parish), Hutton Hall (Hutton parish), and Wedderlie (Westruther parish), though still occupied, have been merged in houses of later date, and some of them have been largely transformed. The ruined keeps number sixteen.

Of houses of the seventeenth century still inhabited Wedderlie, which is unaltered, and bears the date of 1680 is a good example. The castle of Thirlestane, near Lauder, though considerably added to in modern times on the west front, is the most remarkable historical dwelling in the county, and its plan is unique among Scottish mansions. The houses of Nisbet, Cowdenknowes, Hutton Hall, Houndwood (Coldingham parish), and The Hirsel (Coldstream parish), all of which have been enlarged or modernised, still retain ancient features of interest. Of the ruined houses of a defensible character, Greenknowe Tower in Gordon parish is the best example.

Moated Mound.

The only example of this kind of construction in the county is on the Castle Law estate, parish of Coldstream. It seems to have escaped particular attention hitherto, but it is a very good example of a class of constructions now generally recognised as defensive works of early Norman date.

Prehistoric Remains.

1. *Defensive Constructions.*—In this connection we may take first the constructions noted under the general heading of forts on the Ordnance Survey maps. These, for purposes of observation, fall naturally into four geographical divisions:—(1) Those in the vicinity of the coast; (2) those inland; (3) those in the hilly districts of Lauderdale and adjoining parishes; (4) those that are occasionally to be found on isolated eminences or other defensible sites throughout the south-eastern or lowland half of the county. In the first division may be noted the enclosure on Ewieside Hill, Cockburnspath, surrounded by three ramparts, for the greater part in excellent preservation; it shows unusual features at the entrance to the interior. Attention may also be drawn to the large number of enclosures which have been obliterated in this parish. In the region around St. Abb's Head and Coldingham Loch lies a remarkable group, whereof the survival is no doubt due to the fact that many of the enclosures occupy the summits of small rocky eminences unsuitable for cultivation. The second division includes a remarkable series of enclosures beginning at Warlaw Hill, in Coldingham parish, and running along the ridge of Bunkle Edge, through the parish of Bunkle and Preston, till it terminates on the south slope of Staneshiel Hill, in Duns parish. The most noteworthy among them is the fort at Prestoncleuch, surrounded on two sides by three ramparts, which here and there are 10 feet to 12 feet in height. In the third division of the county prehistoric defensive constructions are both numerous and important. In the parish of Lauder there are fourteen, the most conspicuous examples of which are Longcroft, containing numerous foundations; West Addinston, where the inner rampart on the north-west is still 17 feet high, and at the entrance shows curious crescentic depressions traversing the roadway, with circular foundations in the interior; Tullis Hill, a circular construction in good preservation, with a well-defined rampart 12 feet or 13 feet high above the bottom of the ditch, and a stony rampart on the top of the counterscarp; and the Haerfaulds. The defensive enclosures in the southern half of the county are few and unimportant, and have suffered much from the plough.

2. *Sepulchral Constructions.*—Few of these remain intact, and the total number noted in the county is only ten. One of them, however, calls for very special remark—viz., the Long Cairn at Byrecleugh, in the parish of Longformacus, known by the name of the Mutiny Stones. From its external features this appears to be representative of a type that frequently occurs in the north and west of Scotland in association with stone age burials, but it is the only one of its class hitherto noted in the south-east. There is only a single stone circle in the county—that situated on the moor to the north of Lauder. It is of large diameter, has the greater number of its upright stones still *in situ*, and does not appear to have been excavated. The stones seem small, but the soil in which they are sunk is peaty. There are the remains of cairns in the neighbourhood. The Twinlaw Cairns, in Westruther parish, though conspicuous landmarks throughout the county, have been excavated and reconstructed.

Miscellaneous Objects.

Earthhouse.—Belonging to the prehistoric era is an earthhouse at Broomhouse, in the parish of Edrom. The entrance has been covered with earth for preservation of the structure.

Village Cross.—The village cross at Cockburnspath is worthy of remark. It is a handsome structure, bearing on the four faces of its capital alternately thistles and roses, and is kept in good repair.

It is perhaps desirable to note that there is no recognised Roman construction in this county.

A PRACTICAL TOWN.

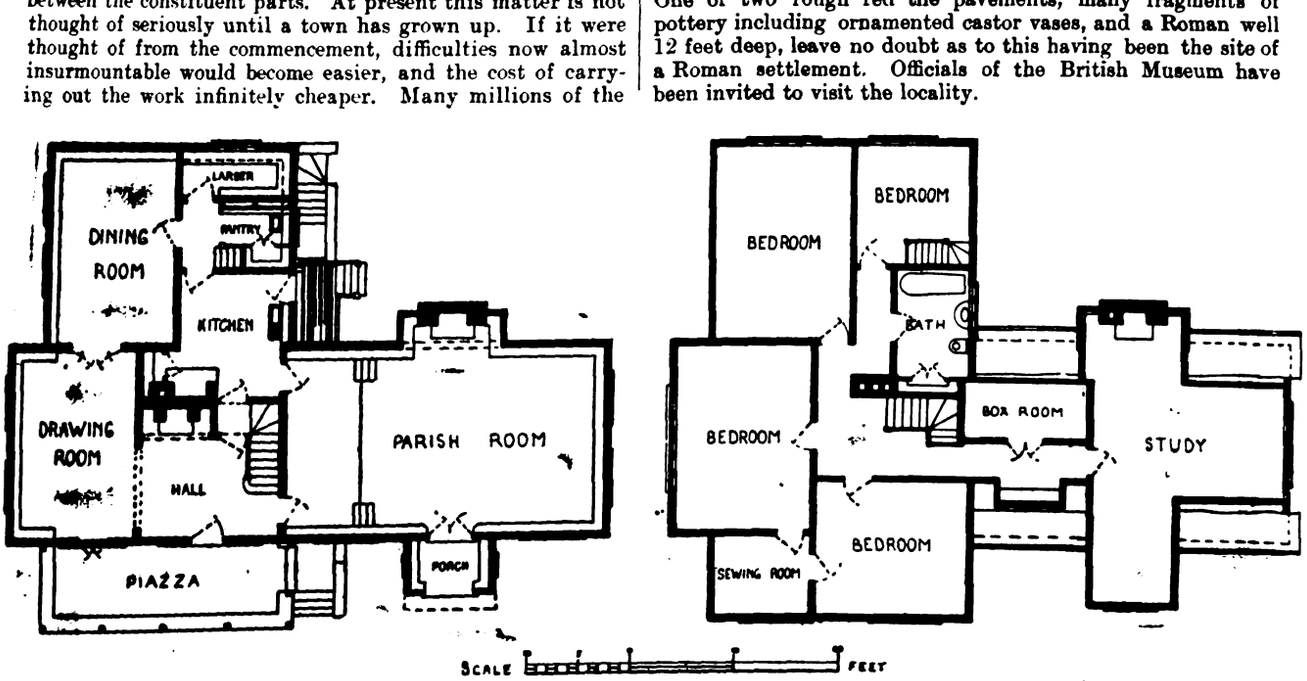
IN connection with the Town-Planning and Housing Exhibition that has just been closed at Hampstead, a lecture was given on the 4th inst. by Councillor J. S. Nettlefold, of Birmingham, on "A Practical Town," i.e., one suitable for a commercial centre. Commercial centres are, he said, composed of public buildings for administrative, religious, recreative, educational and other purposes. (1) Manufactories, warehouses, offices and shops. (2) Private dwelling houses and public parks, playgrounds, open spaces and allotments. (3) And, in completion the means of communication which require at least as much careful forethought and planning as any other part of a town. There is unfortunately in our English local government great lack of co-operation, not only between the various committees composing those bodies, but also between those bodies and the directors and private individuals, manufacturers, merchants, house-builders, &c., but perhaps the worst feature of all in English local government is the fact that most commercial centres are governed by several entirely distinct local authorities, each struggling with the other for what it thinks to be its own interests, instead of all pulling together for the common good of those who live in one part of the town, and work in another.

Supposing those difficulties have disappeared, how should we plan our practical town? Administration comes first. The principal buildings for this purpose should be the centre of our town as they are of our civic life, and should be business-like as well as dignified, depending for their impressiveness on beauty of line, rather than on excessive ornament. It is most important also that there should be plenty of free space round this centre. Other public buildings, religious, recreative, educational, &c., should also be placed on main thoroughfares with open spaces around them. Our next concern is the individual employment of citizens. Factories and warehouses should be at the rear of the town, and properly served by railways and canals.

And now we come to the enjoyment of the citizens, the home and its surroundings. In placing business buildings on wide main arteries radiating from the centre in the way suggested, we shall provide oases where dwelling houses can be put. In these districts, the actual roadways should be narrow, with tree-planted grass margins and pleasant footpaths on either side. In England main arteries are far too narrow, and the roadways of side streets far too wide. Open spaces, playgrounds and allotments are a great deal better on back land than when located on valuable frontage, which might be, from every point of view, more profitably used for houses.

Hampstead and other garden suburbs have shown the practicability of what is suggested above. To-day we are not considering mere ideals, we are considering accomplished facts. That brings us to the means of communication between the constituent parts. At present this matter is not thought of seriously until a town has grown up. If it were thought of from the commencement, difficulties now almost insurmountable would become easier, and the cost of carrying out the work infinitely cheaper. Many millions of the ratepayers' money have been spent in this country for pulling down buildings that never should have been put up. Take for instance the large amount of property that had to be pulled down in connection with the making of the thoroughfare from Charing Cross to Portland Place early in the eighteenth century. Similar mistakes have been repeated over and over again; it is only necessary to instance Kingsway. To-day there are happily good grounds for hoping that we, commercial Englishmen, will, as a nation, soon be giving as much attention to the rational enjoyment of our fellow citizens as we have done in the past to their profitable employment.

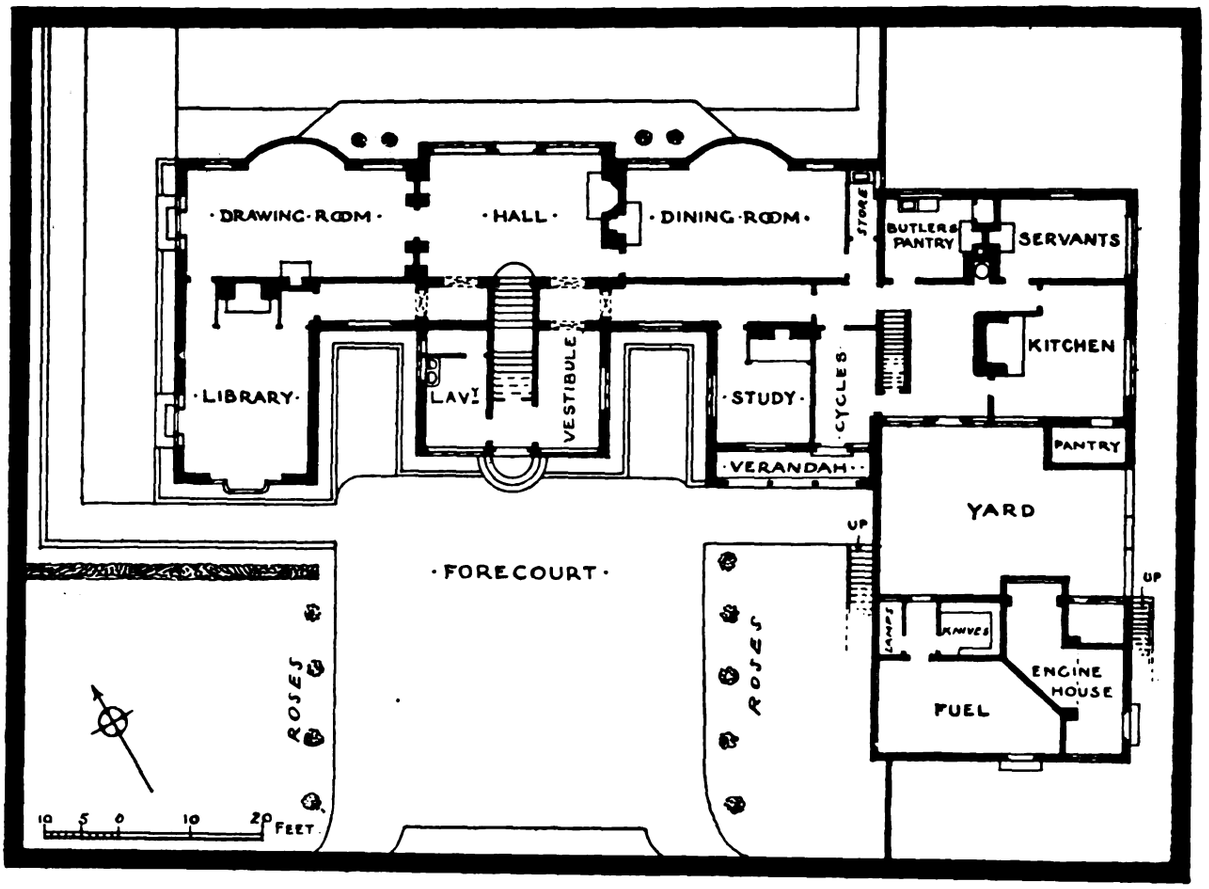
ILLUSTRATIONS.



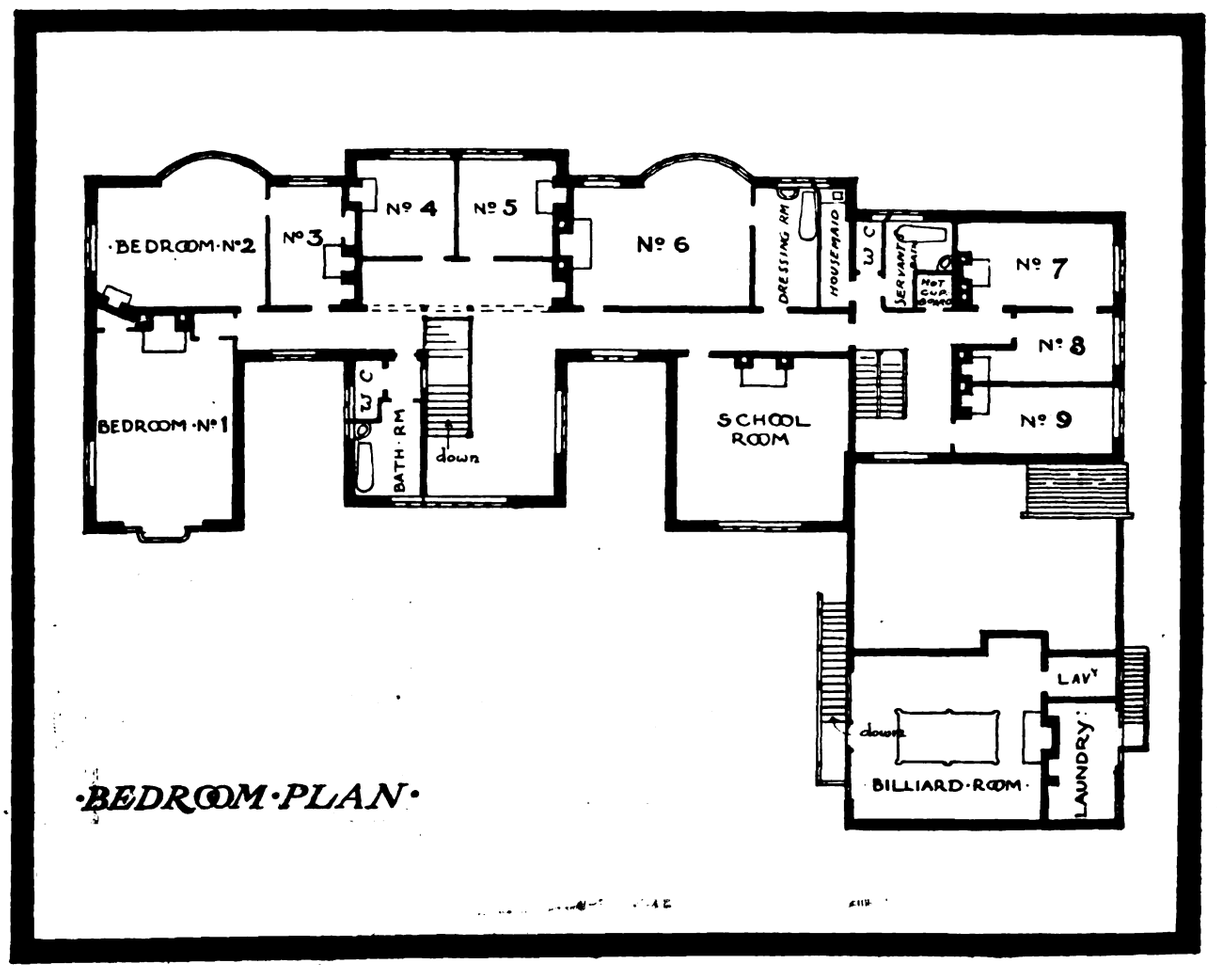
ALLANGATE, RUSTINGTON, SUSSEX.—GARDEN FRONT—FRONT ENTRANCE GABLE—ENTRANCE FRONT.

THIS house faces the main road between Littlehampton and Worthing, from which it is screened by a high rubble wall. It was built for W. Rawson-Shaw, Esq., J.P. Local materials were almost exclusively used, the most noticeable exception being the stone dressings, which are Doulting The bricks and tiles are hand-made. The contractors were Messrs. Cornish & Gayner, of North Walsham. The house was erected from the designs of Mr. R. Heywood Haslam.

RECTORY AND PARISH ROOM, GLYNDON, NEAR BALTIMORE, U.S.A.



THIS building is being started at once. The walls to the cellars, and to a height of 6 feet from the ground, will be built of local stone. The walls above will be of stud-work, faced with half-timber work, and the roofs will be covered with shingles. The walls inside will be plastered and the woodwork generally will be stained dark brown. The full detail plans and specifications were prepared by Mr. R. A. Briggs, F.R.I.B.A., of 12 Norfolk Street, Strand, London, W.C., and the work during construction will be probably supervised by a local architect.



The Foundations of a Roman villa have been discovered on the marshes near the new pleasure ground, Northfleet. It lies on the property of the Associated Portland Cement Manufacturers, Ltd., in a locality where the firm are excavating chalk. In the interests of research, the firm has deputed a workman to carefully excavate the spot under supervision. One or two rough red tile pavements, many fragments of pottery including ornamented castor vases, and a Roman well 12 feet deep, leave no doubt as to this having been the site of a Roman settlement. Officials of the British Museum have been invited to visit the locality.

THEORY OF THE APPLICATION OF ANGLES IN GREEK ARCHITECTURE.

By G. S. Aitken, Architect.

I AM indebted to Professor Baldwin Brown for a suggestion to try and find how far the assumed geometrical system of Classic design applies to hexastyle as well as other forms of Greek temples, and, as may be seen from the accompanying diagram, the result is so remarkable as to place beyond doubt such as the Greek practice.

It will be noted that in two of the cases illustrated the diameters of the columns seem to have been determined by angles of 67½ degrees (the complement of 22½ degrees); a third case gives 60 degrees as the basis of division, and the fourth that of 45 degrees as settling the intervals between the columns instead of their diameters.

It will be observed also that in the two 67½ degrees instances the angle fixes the widths of the outer intercolumniations, which in these cases are narrower than the intermediate spaces.

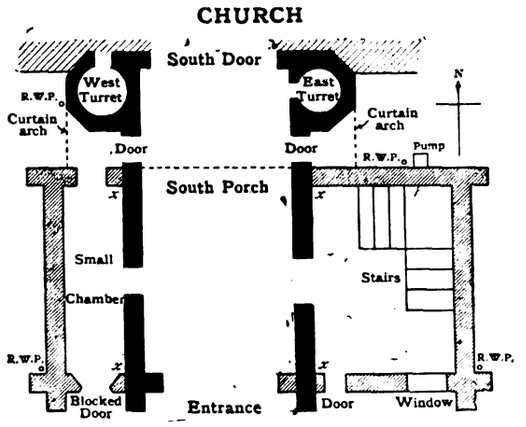
If the Greeks used this system of angles we may conclude they did not take foreshortening into account, or make any correction for it in the mass at any rate, whatever they may have done in detail, and this seems reasonable, as they could only have arranged for corrections suiting one point of view. Their effect would be lost as the spectator moved, and, in fact, would have led to distortion in all other positions than the one for which they provided.

The question still remains for answer, wherein lies the virtue of this system of angles? Well, in this way: they are proportional parts of a right angle that in its turn is a proportionate part of a circle, which, as a geometrical form, embraces all created things. They may therefore be considered as representing something higher than human thought, although the Greeks might not know it, and as such are worthy of respectful consideration. If an architect could approach the standpoint, in however a modified degree, of the great Designer and Former of all (all other things being taken into account), his work would be correspondingly better than that of the man who stood far off on the line of approach.

And so we find the Mediævalist came nearer to the centre than the Greek in his use of the equilateral triangle—the symbol of the three Divine Persons who all had their part in the work of creation; the architectural result was nobler and more aspiring, attaining its greatest in the altitude of Early Pointed, descending in the later phase of Perpendicular, and reaching its lowest in the time of the Renaissance, when pure intellect and humanism shut out the "spirituelle."

There is a quaint motto over the door lintels of many old Edinburgh houses, "Except the Lord build the house they labour in vain who build it," which, though it may not have been intended as an architectural allusion, is worthy of reconsideration in the present day; and we may find after all that the law of three as a counterpart of the Three Persons of the Trinity has its place in architecture after all.

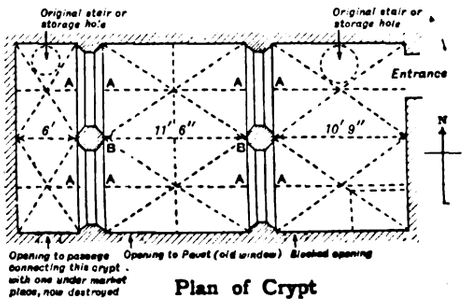
TOWN HALL, CIRENCESTER.



THE thirty-second annual report of the Society for the Protection of Ancient Buildings is a booklet of a hundred and twenty pages, nearly a hundred of which treat of various buildings that have come under their notice during the past year. The committee state that the work of the Society is seriously handicapped by lack of funds, and in consequence they are most anxious that the membership should be largely increased during the current year. Amongst the many schemes that have been carried out in consultation with the Society was the repair of the town hall at Cirencester, Gloucestershire. By permission we reprint the following detailed account of how the work was executed:—

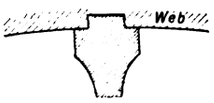
The building consists of the south porch of the parish church, with a small chamber on one side and a staircase on the other, and above, over these, at the first floor level, a large room, now open to the roof (but probably formerly floored at half its height), which at one time was used as the council chamber of the Town Council. This chamber occupies the southern portion of the building. The northern part, that abuts upon the south wall of the church, contains a small chamber, and a kind of gallery over it approached by a turret stair on the west. This lower small chamber communicates with the porch by an east turret, which externally is complete up to the roof, but internally has no steps above the first floor level. The west turret communicates directly with the church, having a door into the south aisle.

The sketch plan shows the disposition of the parts of the building—the council chamber being south of the dotted line. The shaded parts are later work than the dark, showing that the original building was the south porch with the two turrets, perhaps carried up with parapets and leaded roof to the sill of the short window on the south door of the church. No actual trace of such a roof was found, but that the ad-



Digitized by Google

joining chamber and staircase were built later is proved by the straight joint in all four points of their attachment to the walls of the porch (marked on the plan *xxxx*).



Ground Plan.

Beneath the old town hall is a crypt, its walls being under these later-added walls of the staircase and small chamber, while stout stone arches carry the side walls of the porch. The crypt is vaulted in stone, with rather obtuse pointed arches. The vaulting is divided into three main parts, corresponding with those above, and the diagonal and transverse ribs have the appearance of being later than the arches that carry the porch walls. For example, the horizontal ridge ribs, where they run to the apex of these arches, are not finished so as to die on to them, but are butted up to them. (See "A" on plan of crypt.) The springers on the transverse ribs beneath the porch are apparently also let

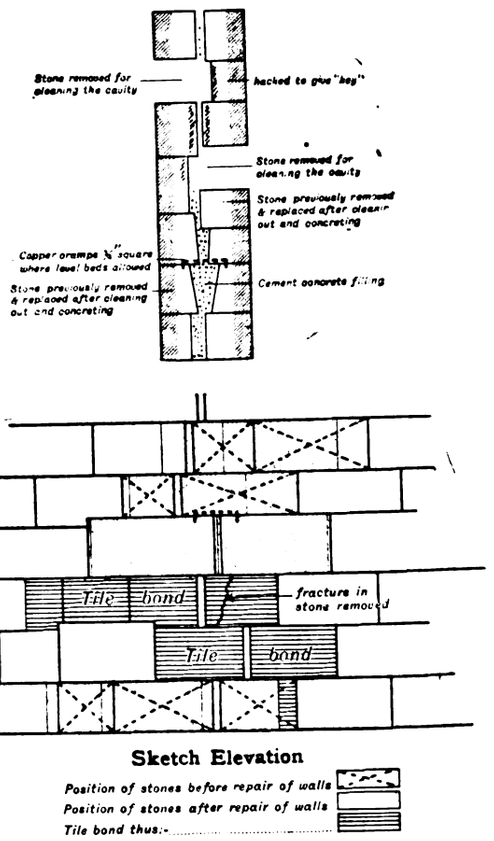
Plan of Crypt

in to the piers of these same arches (see "B" on plan of crypt), and have a straight joint above, so that the vaulting of the crypt appears to be an insertion, later in date than the arches that carry the porch walls. It is probable that this was a contemporary revision. The vaulting ribs are large and simple in profile, and are cut, English fashion, to take the web thus—

which is very well built in thin laminated stones and plastered with a coat of pure lime about $\frac{1}{8}$ inch to $\frac{1}{4}$ inch thick.

At the time when the works of repair were taken in hand, the large arches under the porch walls showed signs of crushing, the soffits having been pinched at the joints so that two or three large pieces of stone had spalled away.

The walls of the crypt are of small stones and the joints were soft and open. These were wedged up with slates in cement and flush-pointed with lime mortar. The masonry of the north-west corner wall of the crypt appeared to be very loose and was cracked; it was found to be saturated with water arising from the pump and from the rainwater pipe outside. The defective work was all taken out and rebuilt in cement with large bonding-stones and concrete.



The vault ribs in several places had dropped slightly, and so had parted from the web. These were supported either by copper hooks let through from the concrete filling above, and down through the stones, or where the length of rib and character of the damage required it by inserting steel joists from wall to wall and from them suspending similar hooks of copper, the whole being thoroughly covered in breeze and cement concrete, and the steel joists painted.

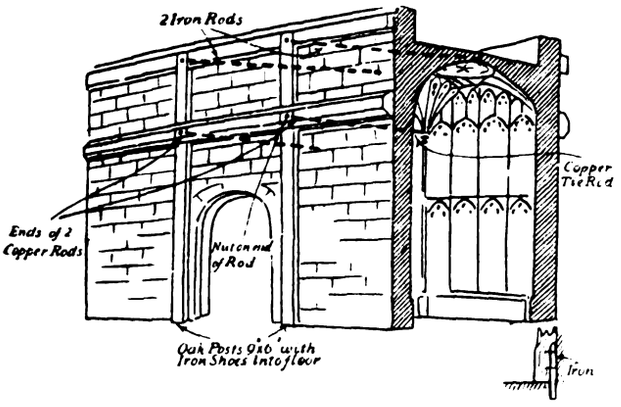
The walls over the arches being made sound, the porch walls were examined and found to be built without any bonding stones from face to face, but, as it were, with an inner and outer surface wall, filled in with lime mortar. The filling was completely dry and loose and the walls showed many large cracks, some being as much as $1\frac{1}{2}$ inches wide from the top to the bottom of the walls. Also, the thrust of the vault of the porch had pushed out the walls about four inches on each side, and thus the vaulting stones were loosened and the arches broken.

The outer—i.e., the west and east outer—faces of these porch walls, when the whitewash had been removed, showed that at one time they had been exposed to the weather.

These porch walls were repaired by removing stones at intervals from each side and cleaning out all the loose core, then thoroughly washing out the cavity and chipping over the backs of the face stones, and then filling in with cement concrete sufficiently fine to ensure its filling all cracks and interstices up to the level of the uppermost stone removed; and so on, working up and over the entire wall from the floor of the porch to the vault and wall top.

Tile bonds, twelve inches or more in depth, according to the height of the stone courses, were inserted on the outer faces of the walls, across the cracks, and the bonding of the stone courses was altered where possible so as to bridge the cracks and form a sound bond. The following diagrams explain this:—

Sketch Elevation



During the progress of this work the porch vault was carefully supported, and when the repairs to the walls had been finished the vault itself was taken in hand.

Examination had shown that this had been supported—probably in 1831, when the building was largely restored—by an oak framework laid on the top of the porch walls, from which depended iron hooks passing through the vault stones and thus hanging them to the framing. It was found that this framing was pressing on the crown of the vault, and that in some places the floor joists of the council chamber were in turn resting on the framework. The method of support of 1831 was adopted and strengthened, the framing raised clear of the vault, and the floor joists re-arranged so as not to rest anywhere but on the walls.

Steel joists from wall to wall were made use of to support the oak framework, three being laid across above it—in the thickness of the floor joists—and the framework hung from them in much the same way as the stonework had been hung from the framing. Additional copper hooks were used as support to any stones that required it. The joints, stoppings and pointing of the vault were all cleaned out and refilled with lime mortar; in the very large joints small pieces of tile were used. The back of the vault and all the open joints were washed thoroughly clean before repointing; and, finally, the pockets of the vaults were filled with breeze-concrete.

Digitized by Google

The side walls of the porch were further supported by a framework of oak beams outside the walls, tied together by two hardened copper rods, 1½ inches square at the springing

level of the vault; while above the vault two round iron rods, one inch in diameter, connected two oak plates, nine inches by nine inches.

The copper rods were then painted stone colour and the floor above relaid with screws to prevent jarring the new pointing.

At the same time as the work of repairing the crypt and porch was proceeding, the three oriel windows on the south front and the parapet were being mended and replaced.

Examination of the windows had shown that they were built on large, strong corbels, of which the inner ends were flush with the inside of the wall. Above these the oriels are built up to the glass level in thin panelling stones, about seven or eight inches thick, with broader string courses at intervals. The windows themselves show three faces, and have stout angle mullions and small inter-mullions crossed with transoms, and, at the half way, with a broad band of quatrefoil work, this being the space between the windows necessitated by the floor dividing the original lower and the upper small chambers, alluded to above.

At five different levels in the whole height of each window had been built a cross bar of iron passing through every mullion, and at either end bedded deep into the walls, the ends themselves turned down cramp fashion, the three lengths being connected by a great hook and eye joint at each angle mullion. These irons had corroded very much, bursting the stonework away from them and causing much dilapidation to the mullions. The mullions were mended with hand-made plain red roofing tiles in cement, and, where possible, portions of the stonework which had split off were re-used.

In order to obviate the recurrence of similar damage, all the iron stanchions and cross bars, where they entered the stonework, were spliced with copper, which at once preserved the old iron bars and stanchions—greatly to the advantage of the appearance of the building from the street—and made an efficient and strong tie round every oriel window, for the tie was continued as before and bedded in the main walls.

At the old floor level, just over the head of the lower half of the oriels, a band of iron had been built in, and this had burst off all the stonework inside the window. The iron was entirely removed from all three windows and replaced by copper in the central window only. Tile lintel-ties were carried across all the oriels at this level. The work at this point became very difficult and dangerous, in the central window especially; but it was accomplished without any crack or settlement. Two bands of tiles were carried round each oriel inside, cutting as deeply into the walls of the oriels as their thickness permitted without showing on the face.

The walls below the glass level were cramped, repaired, and strengthened, while over the whole area of the south wall, including the three oriels, was built a tile lintel twelve inches deep, the ends returning eight feet into the end walls, thus tying back the south wall to the main building.

All broken mullions and tracery were cut out and rebuilt in tile-work in cement, the tiles being cut to the profile of the moulded stones.

Other parts of the front wall, such as the bonding of the buttresses, were found to be defective, and these were dealt with severally.

The entire parapet had been removed previously to the Society taking the case in hand, and the stones were stacked in the churchyard beneath the tower. No key was obtainable as to the meaning of the numbers, partly obliterated and many in duplicate, which marked the various pieces; so that the whole had to be reconstructed from the existing stone sill and from a large and clear photograph taken twelve or fifteen years ago. By means of this photograph stones were identified—even by tiny sand holes and other unevennesses of surface—and finally, with great patience on the part of the workmen, practically every stone was replaced in its original position. In a few cases the stones were so badly broken that they had to be made good with tiles in cement, plastered; and a few single mullions were replaced with new stone.

Where the stones were short in length, tiles were used to build up to them; and copper dowels and cramps and slate dowels were freely used. Two copper rods were built in to support the north-east pinnacle, and two stone buttresses were built across the gutter behind the parapet on the south front, to strengthen it. Some of the pinnacles were badly broken, and were mended with cement concrete; and copper dowels were used in replacing crockets, &c.

The turret stairs were carefully examined and repointed and the joints cramped where necessary. The curtain arches abutting on these turrets had iron ties bedded over them in the walls that form the ends of the dais in the council chamber, with similar results to those in the case of the oriel windows. These irons were cut out and tile bonds inserted from the inner face of the turrets to twelve inches into the walls of the town hall.

The timbers of the roof were examined and the roof itself tied back to the framing of the north wall by iron rods and by irons bolted to the posts and plates of the gallery. The lead roof was repaired, and the gutter on the south front taken up and relaid.

Finally, to protect the external surface of the stonework, it was given three coats of baryta-water, the last being mixed with lime, a little colouring matter being added to temper the hard, white effect which would obtain until the work had become weathered.

A stone inscription commemorating the work is to be placed in the town hall.

REINFORCED CONCRETE.*

Historical.

THE author is fully aware that when dealing with a subject such as "Reinforced Concrete," which is described by some as being "comparatively new," it is customary to preface any remarks with a brief *résumé* of its history, and it is proposed to follow this time-honoured custom, but the reason for so doing is entirely different from that which usually prompts such remarks. Engineers are not greatly concerned with the actual history of the rise of reinforced concrete as a material to be reckoned with in very many branches of their profession, interesting as such history undoubtedly is, but they are most decidedly concerned in obtaining definite proofs of its lasting qualities, and it is only by looking backwards that any reliable data can be obtained as to this.

Firstly, reinforced concrete is not the "new thing," the "experiment," the "unknown quantity" which it is so frequently and erroneously described as being. Of course there are new forms and uses of it which we have not yet been able to test by time as to their durability, but these only represent phases of the development of the material as a whole and do not affect the main question of depreciation, upkeep, reliability, and similar important matters. It is a fact well known to all those who have studied this question, even superficially, that there were important structures in reinforced concrete erected in London in 1889, and which are still in use, and on the Continent can be seen equally large structures successfully built twenty-five years ago and also still in use without having been strengthened or "patched up." It may probably be said that the above instances, being buildings or houses, are not very conclusive evidence to engineers, as they would probably never be loaded up to even the safe loads for which they were designed, and the area of their foundation-plan is practically equal to that of the buildings themselves, and also that they are not subjected to much vibration. We will therefore take the case of bridges, which are subjected to great vibration and the foundation area of which is very much less than that of the whole structure, and we find that there are numerous instances of bridges in reinforced concrete built more than ten

* A paper read at a meeting of the Institution of Mechanical Engineers at Liverpool by Mr. Arthur C. Auden, July 1909.

Digitized by Google

years ago which are still in as good, or better, condition than when first put up. The author does not refer to narrow-span bridges or culverts, but to those of fair spans such as the Eslingen Bridge over the River Neckar with a 60-foot span, fourteen years old, and over the same river at Ybbs with a 140-foot span, twelve years old, the Chatellerant Bridge, 153-foot span, eleven years old, and the Prince Rupert Bridge at Munich with 191-foot span, and ten years old. Instances could be multiplied to a great length, but the author thinks that even these few preliminary remarks will be sufficient to prove conclusively that no one need be "afraid" of reinforced concrete, as it has entirely passed out of its experimental stage, and though failures have occurred through bad design or workmanship, there is no doubt that their proportion is wonderfully small to the total amount of work done—in fact the reinforced concrete "scrap-heap" is the smallest of any material with which we are familiar.

Materials.

An important point in connection with reinforced concrete frequently presents itself, namely, as to the nearest place where the materials, such as sand and gravel or chippings, can be obtained, and it is a question well worth close consideration because in nearly all instances the cost of the proposed structure will be of course affected by the cost of its constituents, and these are in turn much influenced by the cost of freight and carriage. From this particular standpoint it is proposed briefly to classify the materials, as it is by no means uncommon to find that, within reasonable limits, we can, by slightly altering our design, use cheaply-obtained aggregates without in any way materially affecting the use and efficiency of the proposed structure, provided of course that the said structure is not of an ornamental design and does not contain much fine work.

From the above standpoint, therefore, the author will consider, firstly, the stone, that is, chippings or gravel.

In many places the Eastern Counties flint is practically the only stone locally obtainable, but though this makes good, tough concrete, it is unreliable for fire-resisting purposes owing to its tendency to crack and "fly" under heat. The proposing user must, therefore, balance his reduction in capital expenditure by a slight increase in his fire-risk. It is interesting, however, to know that this tendency to crack under heat can be much reduced by passing all the stones through a crusher, as practically all flints have their crystallisation definitely bounded by planes along which they always break, the remaining portions between such planes being comparatively homogeneous, with but little tendency to "fly."

The same remarks apply to limestone, but it has not the redeeming feature of being more fire-resisting after being broken; in fact, it is not advisable to be used at all where fire-resistance is an important consideration, as it is very apt to disintegrate to powder under the action of heat, but it is not to be condemned entirely as it is quite a serviceable material apart from increased fire-risk. It must, however, be remembered that it almost always needs washing before use, as, after breaking, it will generally be found to be covered with fine, blunt dust, which prevents the cement properly bonding with it; the expense of this washing must, therefore, be set against the cost of other slightly higher-priced stone which can be used as received.

Sandstone can be obtained in many parts of the country in almost unlimited quantities, but as a rule it is too soft, too porous, and too absorbent for use in reinforced concrete work. Samples should always be taken and tested by crushing, and if it is found that it will stand about 1½ tons per square inch, and that the difference in weight, when clean and dry, and after being two days under water, does not exceed 8 per cent., it may be safely used.

Quartzite stone is fairly good if not too soft and open in texture, in which case the same precautions apply as for sandstone.

With reference to testing for crushing strengths of either stone or concrete, it must be borne in mind that reliable results cannot be readily obtained by crushing small pieces, say of only about a square inch or so in area; it is always advisable to use larger test pieces, say such with an area of at least 10 or 12 square inches.

As we are considering the subject of aggregates from the standpoint of disadvantages versus cheapness, it is not necessary to allude to the numerous other stones which are quite suitable for reinforced concrete work, such as granite, basalt, millstone grit, breccia, diorite, trap, &c., although there are inferior qualities of them all, but which, as a rule, it does not pay to use.

With reference to what may be called artificially-produced aggregates, broken earthenware and stoneware from the Potteries District make quite a good aggregate, but those who have not had experience with this material for reinforced concrete will be disappointed to learn that the same must be unglazed, thus preventing the use of the many hundreds of tons of broken crockery now existing in some of the older Pottery towns, as the glaze prevents the proper adhesion of the cement, but doubtless this difficulty will be surmounted in time. When using unglazed earthenware such as broken "saggers," care should be taken that the thick and thin pieces are, after being broken to pass the proper gauge, carefully mixed with each other, as a quantity of thin flat pieces together are apt to form beds or planes which are a source of weakness; under any circumstances it is always better to mix some chippings or gravel with all broken earthenware.

Burnt clay and gault are quite permissible materials, provided that they are tough and hard and do not soften or "crumble" after being left in water for two or three days.

Speaking generally, broken bricks are not a good aggregate for reinforced concrete, although they have given excellent results in mass-concrete. They are usually too soft and yield too much blunt dust and have frequently old mortar adhering to them; if, however, they are hard and close in texture and free from mortar they may be safely used.

It is well known that coke-breeze makes an excellent class of concrete, but it must be remembered that such cannot be regarded as being really fire-proof, although some recent tests by the British Fire Prevention Committee, to which reference will be made later, show that this material can "hold its own" very well in this respect; but from its nature it is much less capable of resisting either tensional or compressive stresses than harder and tougher materials, and the question of sulphur is also present. It is, however, quite possible to design a structure in such a way that—omitting the question of the best fire-resistance—a large portion of it can be made with reinforced concrete composed of this usually cheap and readily-obtained aggregate.

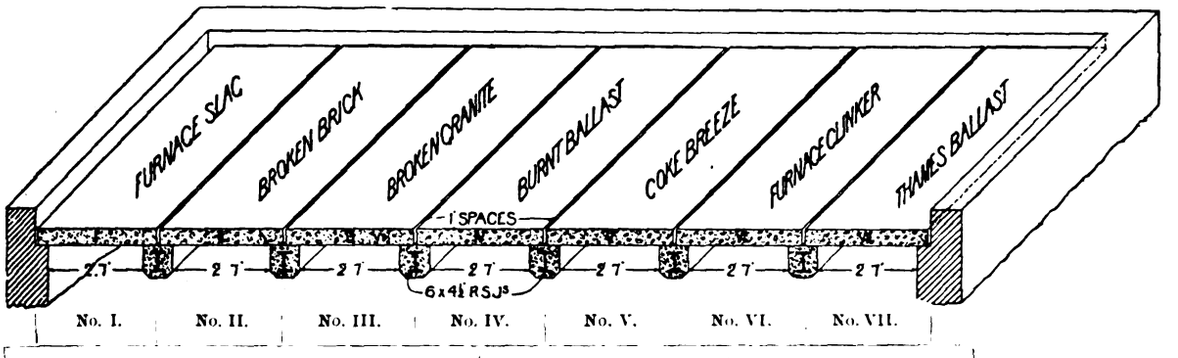
There are very few manufacturers or mechanical engineers who do not make ashes and clinkers, and many have to pay to have them removed. It is, however, quite possible with care to obtain two decidedly serviceable forms of aggregate from these, one being the ashes, which are very similar to coke-breeze, and the other the hard-burnt clinker; but, as with all other materials except the real stone aggregates before mentioned, discretion must be used in the selection of any which are derived from waste products, such as are now under consideration.

In the case of ashes, only those that will float in water and which are of a uniform colour and texture and quite free from adhering pieces of coal and dirt should be used, while with clinker only that which is really hard and clean is serviceable. In both cases, if the washing and riddling or screening are carried out as one process, a more reliable result will be obtained. The question of sulphur must, however, be carefully watched.

Slag from furnaces, whether blast or cupola, makes also quite a good aggregate, provided it is hard and tough and free from dust and its sulphur contents carefully noted.

As is well known, all clinkers, breeze, slags, &c., contain a certain amount of sulphur, which is apt to attack the reinforcing steel with disastrous results. The maximum allowable percentage of sulphur in reinforced concrete aggregates is now being made the subject of tests and experiments—as in fact are all other details in connection with reinforced concrete—and it is to be hoped that an authoritative statement on this subject will shortly be issued, as it is of considerable importance to engineers, particularly to those who have slag heaps of any considerable size; but there is an important point in connection with the presence of sulphur—namely, that if it is in the form of "sulphate" it is practically harmless, but if in the form of "sulphide" it is very deleterious, and anything more than a very small amount indeed should not be allowed.

Care should also be taken with all artificial aggregates that no free lime is present; but, as in the case of sulphur, there are two forms of this material present, one the free lime referred to which is dangerous, and the other carbonate of lime which is practically harmless. It must be noted, however, that washing and exposure to the air and sun will do much to convert the dangerous sulphide into the comparatively harmless sulphate and exactly the same is true with reference to the harmful free lime and its practically safe carbonate. Unfortunately, quite good and accessible aggregates containing lime or sulphur are sometimes con-



Digitized by Google

demned en masse because no discretion is exercised as to the form in which such occur.

Mention has already been made of the washing and screening of aggregates, and it may be of interest to note that "jigging" is a much better method than throwing against an inclined sieve or screen; it has the advantage also of enabling the washing to be done simultaneously with the screening, and also—particularly in the case of the artificial aggregates—jigging knocks the weak corners off and produces better-shaped pieces.

Before leaving the subject of aggregates the author would draw attention to the recent important fire-tests, made by the British Fire Prevention Committee, of concrete composed of various descriptions of material, the proportion of cement, sand and aggregate being identical in each case, i.e. 1-2-3, except with the burnt clay and coke breeze, where there was no sand, the proportion being 1-0-5.

FIG. 1.—*Arrangement and Results of Experiments by the British Fire Prevention Committee with Concretes composed of various aggregates.*

No. I.—Top:—Slab cracked across in two places.
Underside:—Curved downwards ¼ inch; slight cracks visible.

No. II.—Top:—Slab cracked across in three places; slight curve downwards.
Underside:—Curved downwards ¼ inch; slight cracks visible.

No. III.—Top:—Slab cracked across in three places; curved downwards about ½ inch.
Underside:—Curved downwards ½ inch; no cracks visible; about 1 inch washed off by water.

No. IV.—Top:—No cracks; not curved downwards.
Underside:—Not curved downwards; no cracks visible; about 3 inches washed off underside (in parts) by water.

No. V.—Top:—No cracks; not curved downwards.
Underside:—Not curved; no cracks visible; about 1 inch washed off underside (in parts) by water.

No. VI.—Top:—Slab cracked across in two places; curved downwards about ⅛ inch.
Underside:—Not curved; one slight crack visible; pitted in places about ¼ inch deep by water.

No. VII.—Top:—Slab cracked across in very many places; curved downwards about 2 inches.
Underside:—Curved downward 1½ inch; and bad cracks all over in all directions, mainly longitudinally; much washed off by water.

The illustration, fig. 1, kindly supplied by the British Fire Prevention Committee, shows diagrammatically the arrangement of the test which was simultaneous and exactly the same for all the slabs, which were all uniformly loaded to 224 lb. per foot super. The remarks printed beneath each slab are of much interest as showing the behaviour of each material after being quenched with water when practically red-hot. The slabs were all 10 feet by 2 feet 7 inches clear span. Engineers will be interested to know that the furnace clinker mentioned was obtained from off the bars of an ordinary steam boiler, not from destructors.

Sand.

Sand is, in some parts of the country, more difficult to obtain than any other constituent of reinforced concrete. A certain amount is absolutely necessary, and nothing up to the present is known which really and entirely supplies its place. Engineers having foundries will have a ready means of judging sand for reinforced concrete if they remember that, generally speaking, the better sand is for moulding, the worse it is for reinforced concrete. For instance, it must not "bind"—that is, retain any shape when compressed—and it must be incapable of being smoothed with a trowel to a bright surface, or of "standing up" by itself when cut with a shovel; these being "rough-and-ready" methods of ascertaining that the sand has what is required—namely, large sharp grains. Dirt in the form of slime, mud, or vegetable refuse is distinctly bad, but a little loam, enough to soil the fingers when lightly rubbing the sand between them but not enough to make the sand itself adhere to them, is no detriment. Small particles or nodules of clay do not appear to affect the strength of the concrete, provided they are very small both in themselves and in number, but they are not an advisable ingredient and should be avoided if possible, unless there is ample time to mature and test sample pieces of concrete made with the sand containing them.

If sand is scarce or costly some economy may be effected by regarding the very small pieces of the stone or other aggregate below ¼-inch mesh as sand, and mixing them with some real sand. The economy is not so apparent as appears at first because the small pieces must be screened out from the larger aggregate, and in most instances washed to remove the floury dust before being mixed with the real sand ready for putting in the gauge-boxes. It is not good practice to use the stone aggregate and its smalls and dust and some sand upon the chance that they will be in the proper proportions and that the voids and spaces will be properly filled. Experience has shown that this is usually not the case, and although this frequently is the practice with mass-concrete, it should not be allowed in reinforced work, where absolute homogeneity is so essential.

Cement.

With reference to cement there is nothing to remark, as most excellent descriptions of this material are obtainable anywhere, but it should not be one of the many mixtures imported into this country as cement, which do not deserve the name and are costly at any price. Any user is safe if he insists that his cement shall pass the British standard specification in every detail, and that it is purchased from a reliable manufacturer.

Reinforcement.

Since the issue of the first patent with reference to reinforced concrete in 1831—which it is interesting to note was to an Englishman, and, as far as the author's present information stands, this patent out-dates all others in any country—the number of patent systems, forms and methods of reinforcement have been very great, of which many survive. However, it is not now proposed to enumerate the various systems, whether patent or otherwise, but only briefly to draw attention to the advantages and disadvantages of such in each particular instance.

Firstly, it may be said that practically every one of the many systems at present in use has good points in which it is superior to others, but it is also certain that no one system has the monopoly of being the best in every instance and in every form of construction; for example, that which is exceedingly good for beams is inapplicable or unnecessarily costly for use in flat surfaces, and the same may be said as regards others for use in columns and not in arches, and so on.

Secondly, it is frequently cheaper to sacrifice a little of the theoretical efficiency of any method for the sake of ease of handling upon the actual work in progress, as all the metal in reinforced concrete being covered up, any error in position due to misplacement or to any part having become loose or driven or shaken out of place when the surrounding concrete is being punned cannot be seen and put right. It will therefore be readily recognised that any methods involving loose pieces, or such fastened together at many points with small diameter wires, are not so efficient in actual work as those where all the parts are rigidly fixed together.

It is also important that all reinforcement should be so designed as to possess a considerable amount of initial

Digitized by Google

rigidity, so that it does not "sag" or "warp" or "twist" when placed in position in the mould-boxes. Many illustrations regarding this could be quoted, but that of compression-bars, intended to be above the neutral axis in a beam, sagging down by their own weight till a portion of their length is below the said axis, where it is worse than useless, is not by any means as rare as it should be. The same remarks apply to lateral misplacement, particularly in the case of columns and struts, as well as to the pitching and spacing of reinforcing bars or metal on flat surfaces, such as floors, walls, &c. In these last-mentioned it is practically essential to have the bars or metal so designed that it cannot be knocked out of place, as it is almost impossible to keep a number of separate loose bars in proper pitch; it is advisable, therefore, that all reinforcement for this form of work be woven together as shown in fig. 2.

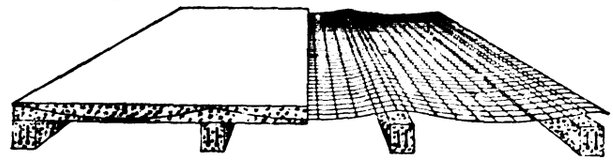


FIG. 2.

Reinforcement of Flat Surfaces: Wires or Rods held in pitch by weaving.

Punching or slitting solid plates into strips or bars is another efficient form of reinforcement for flat surfaces, particularly for those which are approximately square in plan—viz. where the strains are practically equal all over; but for flats where the length is considerably greater than the span a wire meshing is cheaper, as the cross-span wires take the load, the longitudinal ones being only necessary to keep the others in pitch, and it is not advisable to pay for metal and strength in the longitudinal direction where it is not wanted.

Auxiliary Tension Members in Beams and Slabs.

An examination of all the accepted specifications for the last ten years dealing with reinforcement, or a reference to the advertisement pages of technical journals, will show that it is almost universally acknowledged that these important accessories must be inclined to the main tension-bars, and not be at right angles thereto, and also that such bars must be so designed as to retain absolutely their positions where they are connected to the main tension-bars, and cannot be slipped or moved along the same when ramming the concrete or otherwise. The reason for this inclination will be readily seen on examination of a slab breaking under a test load. It will be seen that the cracks are not normal to either the neutral or transverse axis, but are at an angle thereto, and it is known that the most efficient way of preventing any two surfaces from coming apart is to spike them together with a nail at right angles to themselves. This reinforcement is therefore designed so as to pass through the weak portion of the beam or slab where cracks are likely to occur, at right angles to such cracks (or planes of rupture), this reinforcement being, of course, in addition to the main tension-bars taking the main tensional stresses below the neutral axis of the beam. It is not such good practice, though frequently exceedingly convenient, to obtain auxiliary tension members by means of placing a large number of rods or bars in the bottom of the beam and bending up the ends of them at various points, although by this means the desirable inclination above mentioned is gained, but this design involves a considerable excess of metal at the centre of the beam, and a greater weight of steel than is required must be purchased.

Reinforcement of Struts and Columns.

There are two very distinct methods of reinforcement in use for these—one being that in which the vertical bars are prevented from spreading by being spirally wound with rods or wire, and the other where the same end is obtained by means of rings or loops of wire tying the vertical bars together, such loops or rings being arranged at various distances apart to suit the design and strength desired. Both these methods have good and bad points, each one being the best under appropriate conditions.

The spiral winding has given most excellent results, and is considered by many to be the best for columns, &c., as it permits the use of lighter and fewer vertical rods, but it has the disadvantage of being somewhat difficult to make it a "good mechanical job"—that is, so that the spirals shall all be the same diameter and parallel in bore, otherwise some will clasp the group of vertical bars too closely and others hardly touch them, which results in unequal stresses. This is, however, generally made much easier by using bands of flat rectangular section which bend readily, and by first winding the spirals on a cylinder and then slipping them over the vertical bars when made. Great care must be taken when using spiral reinforcement in vertical columns that it is not made in too long lengths, as all the concrete has to be put in from the top of each length, and it is well known that when concrete is dropped from even a small height the mixture of its constituents becomes very uncertain. Care must also be taken that each length of spiral is "corkscrewed" well into the one below it, as otherwise there is a plane of weakness between each length of spiral. This form of reinforcement must be so designed that the required strength is obtained without the pitch of the spiral being closer together than the size of the largest pieces of aggregate used, as if it is so the stones become jammed between the coils and a lack of homogeneity is the result. In the one case of a column being tested to destruction it is very interesting to note that, notwithstanding the concrete being of the highest quality and very carefully matured (being nine weeks old), it failed before the vertical reinforcement, which was not broken. In the column the vertical rods were ¼ inch and the spiralling ⅛ inch in diameter, and the column itself 12 inches outside diameter. The spiral binding, however, does not always break before the vertical rodding.

The second method of column and strut reinforcement above mentioned—namely, loops or rings slipped over the vertical bars and held at the proper distance apart, as shown in fig. 3—is also an excellent one, especially when the loops are carefully made mechanically on hard metal formers, so that each one is an exact replica of its neighbour, the result being that each one equally clasps the group of vertical bars, otherwise should one be tight and the other slack the bursting strains will not be taken up by all the loops in equal proportions. As the first desideratum of this design of column and strut reinforcement is the prevention of the vertical rods spreading apart under the load (the loops themselves, being further apart, do not resist the bursting strains on the concrete to the same extent as the spiral windings), it is not good practice to allow the loops to be curved in between the points where they touch the vertical bars. Unless the wire or rodding forming the loop is straight between its resistance points it does not get a chance to develop its tensional strength, as it must "pull itself straight" first, which it does at a low stress. For this reason the use of comparatively high-carbon steel is often recommended for columns or strut loops, as it is stiffer to resist distortion, and as distortion is one of the main things to avoid, particularly in this phase of reinforcement, the use of harder steel, if the same can be obtained without any marked increase in cost, appears to be certainly indicated; in fact, as the elastic limit of all reinforcement is almost of as great importance as its ultimate strength, the use of bars and rods possessing considerable resistance to stretching is certainly to be recommended, provided that the said ultimate strength is not appreciably decreased. The use of high-carbon steels has been recommended for various other reasons.*

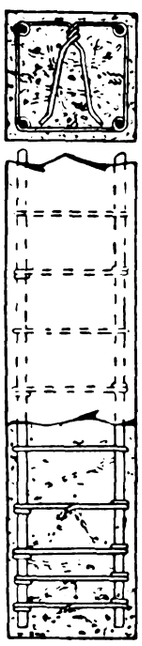

FIG. 3.

Arrangement of column reinforcement with vertical rods and loop-pieces.

It is often said that it is immaterial whether the reinforcing rods are bent or not, as, being bedded in concrete, they are immovable, and doubtless this may be true in a structure where there is no vibration and where the loads are unvarying in amount and disposition; but where it is not so, there is a tendency on the part of the concrete on the concave side of the curved pieces of wire or rodding to become friable, and this tendency should be eliminated in the design by working the reinforcement in straight lines whenever possible. It

* Mr. Charles F. Marsh, in a paper read before the Concrete Institute, stated:—"For hooped members, if the allowable compressive stress in the concrete is higher than about 1,000 lb. per square inch, it is advisable to use high-carbon steel for the longitudinal reinforcements, and the employment of high-carbon steel for the bindings is always advisable. For the purpose of resisting temperature stresses there is an advantage in the use of high-carbon steel, as its greater resistance will enable it to offer more assistance to the concrete."—*Transactions, Concrete Institute*, vol. i. page 7.

Digitized by Google

should also be noted that all the joints of the vertical rods in columns and struts must be in close-fitting sleeves—preferably of good quality lap-welded steam barrel.

When designing reinforcement there are of course many points for consideration quite irrespective of the particular method of constructing or attaching the various parts or members, one of the principal being that all beams or floors running continuously over the tops of columns or stanchions or walls must be reinforced above their neutral axis where they pass over the said columns, in exactly the same way as they are reinforced below that axis in their clear span, as the parts in tension and compression are reversed in these circumstances. In one well-known system the bars are run along both top and bottom surfaces from end to end, but these rods or bars in the compression area are only provided as a means of keeping the shear members or loops or stirrups in position, not as reinforcement against reverse flexure nor as such in compression, this last not being needed unless the area above the neutral axis is such that it cannot stand the allowable crushing stress.

The exact position of this neutral transverse—or, more correctly speaking, diagonal—plane of "reverse flexure" has not so far been very exactly located, and it will of course vary with every variation in the distribution of the load. The present practice is therefore to design the reinforcement over the supports to overlap the ends of that which runs along the "belly" of the beam. The diagonal auxiliary shear members connected to each of the main tension-bars above

FIG. 4.

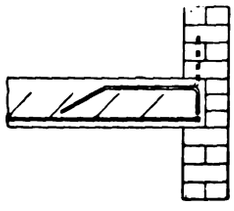

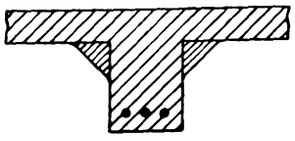

FIG. 6.

Diagram of section of beam and floor showing increased area of concrete in compression.

and below the neutral axis thus become parallel to each other, as shown diagrammatically in fig. 4, in the same way as the tension members in a lattice girder. The same arrangement must be carried out where the ends of beams rest on and in walls, and the diagram fig. 5 shows this reinforcement against tension due to the same reverse flexure above the neutral axis under these conditions. As will be noted, the ends of the bars are bent downwards into the beam itself when only the beam is in reinforced concrete, but, should the whole structure be of this material, the beams and walls consequently being all monolithic, it is better practice to bend the bars upwards as shown in the dotted lines, this being also handier, as the men can readily see, and if necessary adjust, any bar which may have been displaced by punning or otherwise.

When designing long and deep beams or girders, such as for a railway bridge with flat (not arched) spans, it will also not infrequently be found that the available area of concrete in compression above the neutral axis is such that the stress per square inch is more than the concrete will safely stand—that is, more than 550 to 750 lb. per square inch, according to the class of concrete and the nature of the aggregate used; but this is easily overcome by using reinforcement in the compression area, always remembering that the value of steel in compression is 50 per cent. less than that of the same in tension. Here also the question of rigidity to resist deformation under compression is important, exactly as it is in columns and struts, and care must be taken that all the separate members in compression are properly braced together to avoid the tendency to spread in any direction, but particularly sideways and downwards. Even with ordinary beams supporting floors this question of the available area of concrete in compression demands consideration, but the floor and beam being all in one solid piece, not only does the part of the floor immediately over the beam contribute to the desired area, but portions of the floor on each side of this are available also, thus enabling us to regard the beams as of T section, as shown in fig. 6, but, except under special conditions of loading, the breadth of floor which we can consider for the purpose of this calculation should not exceed four to six times the breadth of the beam itself, according to the class of concrete and the nature of the aggregate used. But even with this reservation, this fact of the beams and floors being solid together enables a wonderfully strong and light structure to be obtained. The same diagram also shows in closer section an additional means of obtaining this larger area of concrete in compression—namely, that of making fillets at the junction of the beam with the floor.

Another point to be remembered is that temperature stresses must be carefully guarded against, and that extra reinforcement—in fact, increased scantlings over all—must frequently be adopted for this purpose, as the coefficient of expansion of steel and of concrete is practically the same. In structures such as bridges these variations due to the temperature can be arranged for by the ordinary hinges or expansion joints (of which the latter can be very rapidly and effectively made with thick sheet-lead, the area being such that no pressure it will experience will cause it to "squeeze out"), but in the case of structures where such are impossible, as, for instance, in an exposed tank or bunker or silo, the only remedy appears to be a general increase in strength, particularly by means of increased reinforcement, and, although perhaps contrary to theory, this method has proved perfectly successful.

(To be concluded.)

NOTES ON BOOKS.

"Small Estate Management." By Albert C. Freeman. (London: Rebman, Ltd. 2*s.* 6*d.* net.)

THE author of this handbook has apparently put before him the very laudable aim of rendering the financial position of the small estate owner as sound as possible by making the property itself sound. There is throughout an air of severe practicality which commences with the opening page of the Introduction. The first chapter emphasises the necessity for system if the estate surveyor is to obtain the best results for his employer, very briefly in passing alludes to the claims of concrete for use in places where bricks have to be obtained from a distance, and gives a general sketch of the various duties that will come under his notice. A broad account follows of the Small Holdings Act, 1907, which the author anticipates will be as much a success as its two predecessors were failures. But this second chapter, as well as its supplement, Chapter V., however interesting it may be, is somewhat outside the range of the book, unless the estate surveyor can turn to account the plans given of buildings for small holdings. A highly important factor in estate management is local legislation. Of late years much has been heard of this question, and the results of the agitation are to be seen in a gradual extension of facilities which will no doubt ultimately be as wide as is desirable. There are, it must be remembered, emphatically two sides to any proposed abatement or amendment of bye-laws, and the Local Government Board have to strike a golden mean between them. The remarks on planning and construction contain a lot of concise information. The estate surveyor has generally to take things as they are, and he may often find himself unable to do more than wish he could follow the advice given in the book; but it should often prove useful to him.

"Visitors' Guide to Westminster Abbey." By Francis Bond. (London: Henry Frowde. 1*s.* net.)

This book no doubt will admirably and exactly fulfil its purpose. This being admitted, it may seem a contradiction to describe it as disappointing. But our complaint is that

Digitized by Google

Mr. Francis Bond has thought too exclusively of the visitor who has to cram as much sightseeing as possible into the half-hour or so that can be spared for "doing the Abbey." For those excellent people there are already all-sufficing guide-books, even omitting the accounts included in the guide-books to London. From Mr. Bond we should have preferred a "Short History of Westminster Abbey," instead of a Visitors' Guide. The former would afford him scope for his highly specialised knowledge, while the latter actually shows him as nothing more than a painstaking historical investigator. In a word, what we want is more of a structural historian and less of an erudite cicerone. This wish could be easily met by the addition of a fairly long introductory chapter, giving in outline the story of the present building, of its predecessors, of its place in London and national life, not forgetting its architectural influence and interest. Mr. Bond may reply that all this is amply dealt with in his large work, "Westminster Abbey." Indeed, the opening lines of his preface explain that "The Visitors' Guide consists of the seventeenth and part of the eighteenth chapters of the writer's larger work on Westminster Abbey. It deals principally with the monuments and other objects of interest in the church and cloisters." Those who find the structure of more interest than its contents may therefore be disappointed; nevertheless, the casual visitor cannot fail to be grateful for the reprinting of these two chapters, which tell him all that he cares to know and considerably more than he is likely to remember. In addition there are thirty-two clear photographic plates, as well as other illustrations. The guide-book sets out from the north transept and most conscientiously mentions every memorial, beginning with the "big and ugly monument to the elder Pitt, Lord Chatham," and ending with "the monuments in the west aisle of this transept, which are, however, for the most part of little interest." But this is of course an unlucky starting and ending point to a splendid itinerary, in which almost every inch of the way is made to speak of its historical connections. Many are the curious pieces of information that are given. It is worthy of remark that Mr. Bond pays the scantiest attention to the great dead of the immediate past who have been laid to rest during the last fifty or hundred years in the nave and choir aisles. Generally the name only is given. Yet the names of Livingstone, Robert Stephenson, Charles Barry, Outram, Darwin, and Lord Kelvin must convey more to the minds of most visitors than those of Lord Russell, Robert Waldeby, the Duchess of Somerset or Queen Anne of Bohemia.

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *American Architect* issues a special number on the architecture of Princeton University, which is nearly all based, more or less closely, as regards the buildings illustrated, on the style of the colleges of Oxford and Cambridge prior to the Renaissance influence. Several firms of architects are represented—Messrs. Cram, Goodhue & Ferguson, Messrs. Frank Miles Day & Bro., Mr. H. J. Hardenbergh, Messrs. Parish & Schroeder. The unity of feeling imparted by the work illustrated is the result of an endeavour to construct a harmonious scheme, both topographically and architecturally, in place of the somewhat heterogeneous and haphazard collection of buildings with which the University grew up.

Berliner Architekturwelt gives us some further examples of the modern "new art" architecture of Berlin in the form of flats and office buildings, with a variant in the Geschäftshaus Marcus, in which conventional motifs are used with a distinctly modern handling, thus showing originality without an affected disregard of the past. Some picturesque suburban houses of moderate size and a medley of various details and parts of buildings make a relief to the more solid subject.

Der Profanbau illustrates some extensive blocks of flat dwellings with shops below at Charlottenburg, Berlin, in which a studied irregularity of grouping, partly suggested by the nature of the site, is adopted, and successfully combats the tendency to monotony that flats are apt to engender. The detail is of course "new art" but clever, and sculpture is skilfully incorporated. The Hotel Vent at Oetztal, in the Tyrol, adopts the characteristic local colour by a liberal use of wooden balconies. The Glückerthaus at Darmstadt affords an excellent example of the best type of modern internal architecture of Germany.

Deutsche Bauzeitung gives some more good illustrations, "architectural and otherwise," of Cairo, apropos of the International Archæological Congress.

A Construcçao Moderna shows how restless and incoherent is the design of some modern Portuguese domestic architecture in a house of considerable size at the corner of the Avenidas Ressano Garcia and Martinho Guimaraes at Lisbon.

Il Monitore Tecnico gives the programme suggested by the Italian section of the permanent committee for the International Congress of Architects to be held at Rome in 1911.

Arkitektur og Dekorativ Kunst has some good illustrations of the fine wall-paintings by Emanuel Vigeland in the Vaalerengens church at Christiania.

The *Engineering Record* gives a paper read before the American Society for Testing Materials by Professor H. C. Berry on "Tests of Bond of Steel Bars embedded in Concrete," which is of interest, and compares the results obtained by testing beamwise and vertically, whether "push-out" or "pull-out" methods were used. A good piece of reinforced concrete work is described and illustrated in connection with the Mont Carmel wing of the Château Frontenac, the famous hotel at Quebec.

NOTABILIA.

THE *Connoisseur* deals with the King of the Belgians' collection of old masters, and illustrates some of the examples of old Dutch and Flemish masters, about forty in number, that were sold and transferred to Paris. An interesting article is included on Mrs. Beauclerk's collection of fans. The history of English costume, by Dian Clayton Calthrop, now reaches the time of Edward III.

The *Antiquary* has a short but interesting article, entitled "A Chat about Chests and Coffers," by F. C. Hodges and W. A. Dickins, and another on "The Abbey of St. Eloy, Noyon," by J. Tavenor Perry.

GENERAL.

Among the Illustrations included in the paper on "Ware," read before the Upper Norwood Athenæum, which was reprinted in our issue of last week, was one showing the "Open Roof, Ware Priory, Herts." It should have been mentioned that the illustration was from an engraving in *The Builder* for July 21, 1849, and was reproduced by its permission.

Mr. John Wornham Penfold, of Courts Hill, Haslemere, surveyor to the Goldsmiths' Company, who died on July 5, aged eighty, left estate valued at 62,071*l.* gross. He bequeathed 500*l.* to the Surveyors' Institute, 150*l.* to the trustees of the charitable fund of the Surveyors' Club, and 100*l.* to the Benevolent Society of the Royal Institute of British Architects.

The Wimbledon Town Council last week decided, on the report of Mr. Simpson, architect, London, not to attempt to extend the municipal offices on the present site in the Broadway, but to erect new offices in some other part of the town. The proposal is to be vigorously opposed.

The Dean and Chapter of Winchester Cathedral propose to offer the famous Inigo Jones screen which formerly stood at the entrance to the choir to the Victoria and Albert Museum, London. The screen had been offered to the city authorities, but as it was not considered that the proposed precautions for its preservation were sufficient the offer was withdrawn.

At a Meeting of the Welsh National Museum Council, held at Cardiff on Saturday, the proceedings of the building committee, which met in London, were approved, and a form of advertisement was agreed upon inviting architects to compete for the proposed building.

A Ruskin Exhibition has just been opened at Keswick, and is to continue during this and the succeeding month. It was organised in its main features by Mr. Gill Parker, curator of the Ruskin Museum, Sheffield, from which most of the exhibits have been drawn; others come from Brantwood, Coniston and other private collections. In the first series of pictures from the museum at Sheffield are to be found examples of the work of a band of artists whom Ruskin had working for him on the Continent to illustrate ecclesiastic, domestic and civic architecture. They were originally intended for a projected work which was to deal with picturesque examples from France, Switzerland and Italy, including the architecture of Venice.

In View of the continued interest in the exhibition of collected works by Ford Madox Brown at the Leicester Galleries, Messrs. Brown & Phillips have decided to keep it open throughout August. The chalk drawing entitled "Convalescent," executed in 1872—a portrait of Mrs. Madox Brown—has been purchased by the Metropolitan Museum of New York.

FORTHCOMING EVENTS.

Saturday, August 28.

Architectural Association: Camera and Sketching Club, Visit to Hayes, Harmondsworth, and Harlington.

Thursday, September 9.

Paint and Varnish Society: A paper will be read entitled "The Painting of Plaster," by Mr. W. Fourniss.

Saturday, September 11.

Society of Architects: Students' Sketching Party.
Architectural Association: Camera and Sketching Club, Visit to Guildford and district.

Monday, September 13.

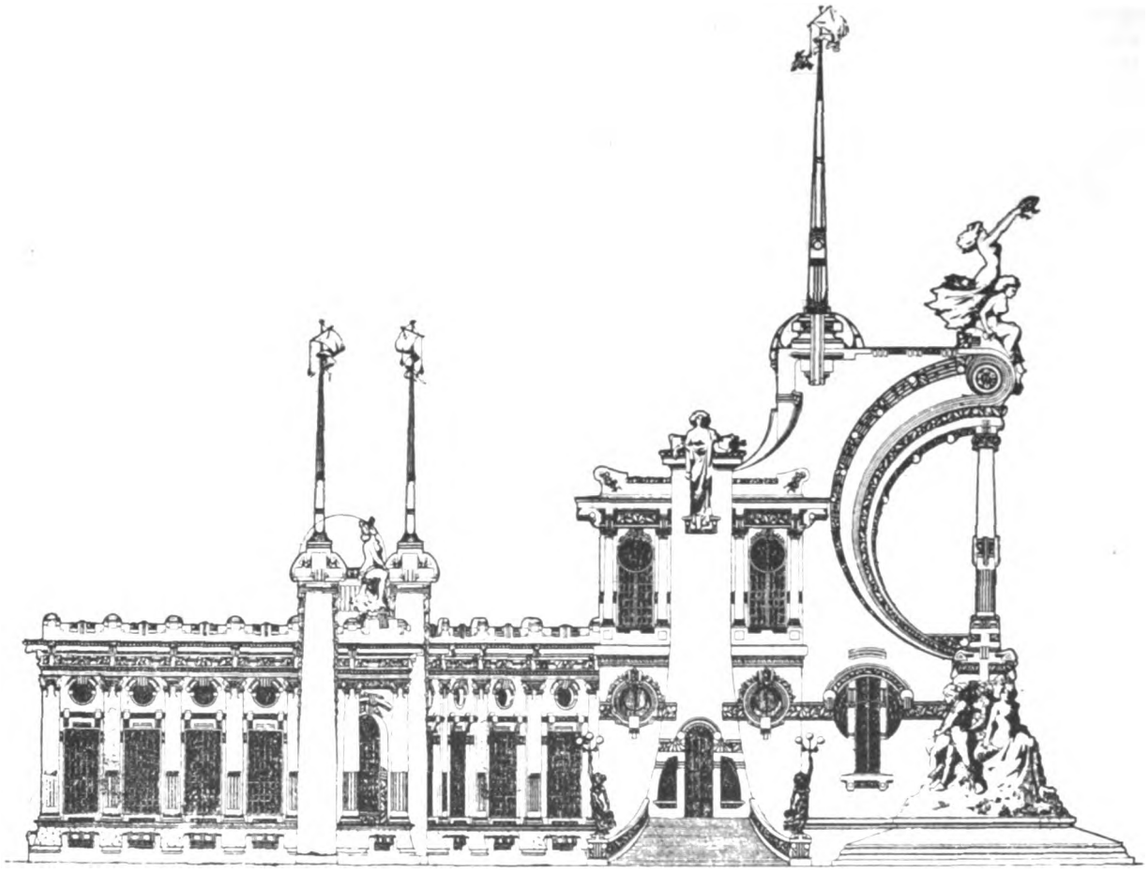
National Association of Master House Painters and Decorators of England and Wales: Annual Meeting at Sheffield, September 13 to 18.

THE A.A. EXCURSION—CHELTENHAM.

(*Concluded from page* 98.)

CHIPPING CAMPDEN is a town of very great antiquity, supposed to have derived its name Campden from a congress of the Saxon chiefs confederated for the conquest of Britain, held here in the year 687. "Chipping," of course, refers to its function as a market town. In the fourteenth century Chipping Campden became noted as a staple town for wool, and was the residence of many opulent merchants, who exported a great quantity of that article to Flanders. The ancient Woolstaplers' Hall was lost to sight for many years, though traditionally one of the old houses in the town was so called. Mr. C. R. ASHBEE bought this house, and, opening up some of the parts obscured by modern innovations, discovered evidence that justified the tradition. This he pointed out to the excursionists, and explained its significance. Campden remained prosperous through the fifteenth century and until the Flemings settled in the western part of England, bringing with them the manufacture of woollen cloth to the place of production of the staple, and then gradually the prosperity of the town declined, for which combination of circumstances we have to thank the preservation of the great amount of old work that makes Chipping Campden so attractive to the student of architecture. A magnificent mansion was erected here by Sir BAPTIST HICKS in the early sixteenth century, of which only a few fragments remain, as it was destroyed by its owner at the commencement of the civil war in the reign of CHARLES I., to prevent its being garrisoned for the Parliamentarians.

The church is of very late fifteenth-century work, and is a magnificent example, large and well designed, with a fine western tower and some excellent monuments. Here the party were met by Mr. C. R. ASHBEE, who described the building and afterwards escorted them to his own house, the ancient Woolstaplers' Hall, and the workshops of the Guild of Handicraft, which have been removed hither from Essex House, Mile End. All too little time remained for sketching—in fact, days rather than hours can be profitably spent at Chipping Campden in the study of old work of various dates from the fifteenth to the seventeenth century, and a return was made to Cheltenham by rail from Campden station.



Wednesday was devoted entirely to the cathedral city of Gloucester, to which the party journeyed by train. After an hour or so "go-as-you-please," the members gathered together at the cathedral, and were met by Mr. F. W. WALLER, the surveyor to the Dean and Chapter, who showed them round and gave a very interesting account of the way in which the fifteenth-century men encased the Norman structure and of recent works and discoveries. Thus Mr. WALLER pointed out that it had been recently found that the vaulting to the south aisle of the nave rises 2 feet higher from the floor-level at the east end than at the west, notwithstanding that the floor itself rises 10 inches in the same direction. Mr. WALLER also explained the repairs that were in progress to the vaulting, much of which had become exceedingly dangerous, probably, in his opinion, as the effect of earthquake. Another subject on which Mr. WALLER enlightened the visitors was the daring construction of the central tower, in which a weight of 4,700 tons is carried upon so small an area of pier that the load upon it is between 12 and 13 tons per superficial foot, and this on a Norman work of freestone casing filled in with concrete. In their endeavour to reduce the superincumbent weight as far as possible, the builders of the tower had cut down the thickness of the upper part of the walls to as little as 8 inches in the panels. The general impression left on the minds of the members was that it would be impossible to persuade any district surveyor or other public authority to allow a modern architect to approach anywhere near the bold audacity of the fifteenth-century builders at Gloucester.

After luncheon the party separated into two main bodies, the one to sketch and photograph in the cathedral, the other to inspect, under the guidance of Mr. TREW, one of Mr. WALLER's assistants, many examples of old work scattered through the city.

Thursday found the excursionists again utilising the railway, and taking train to Bourton-on-the-Water, they then drove to Upper Slaughter, where the manor-house built in the reign of JAMES I. and the church were the items of interest noted on the programme. The church is originally of the Transitional period, the nave arcade having Pointed arches with chevron ornaments. The square and rather low western tower is Early English, with a belfry of Decorated date, at which time many additions and alterations seem to have been made, including a very fine and rich canopied tomb in the north chancel aisle. The chancel is remarkably long—in fact, longer than the nave, which points to a probable monastic connection. The manor-house is of modest size, but a well-preserved example of its date with a charming two-storeyed porch. Internally the staircase and some chimney-pieces of interesting but unpretentious character are the chief features. There is little doubt that the name "Slaughter," Upper and Lower, refers to the great defeat inflicted upon CANUTE by EDMUND IRONSIDES between these villages and Chastleton.

From Upper Slaughter the party drove to Nether Swell, in response to an invitation to visit the house that has recently been finished there from the designs of Mr. E. GUY DAWBER, a recent past-president of the Architectural Association. The excursionists were received by Mr. DAWBER and his client, Mr. SCOTT, and conducted through the grounds and the house. The latter as it now stands and as it is shown in Mr. DAWBER's Academy drawing, which we reproduce amongst our illustrations to-day, is an enlargement of the original house built only

Digitized by Google

a few years ago from Mr. Dawber's designs, and though at present rather new and staring, may be trusted in a short time to weather to the usual Cotswold silver-grey tone, which so pleasantly succeeds to the original bright yellow tint of the local stone. The gardens, too, which are extensive and well planned, want a few years' time before the bowling green will be fit for a match between any decent teams, and before the bronze vases from Paris and bronze sculpture harmonise with the stone walls. Bearing in mind that the whole environment has been created out of a bare hillside, it says much for the skill of Mr. Scott's designer that even in its newness—the work was only finished last June—there is a great deal of charm about both house and garden. When, however, the members were taken into the house, they received a cold douche to their artistic susceptibilities, the effects of which even an excellent luncheon failed entirely to efface. Outside the house we feel that we can understand what a large manor-house of the sixteenth century in the Cotswolds looked like when it was brand new. Inside we are in presence of a modern French attempt at a rechauffé of the work at Versailles, and a rather poor attempt at that, a "salmi," in fact, in which yellow and the present fashionable French grey of Paris are the principal flavouring of disjointed design in plaster. Mr. Dawber apparently had to stop outside whilst the interior of his design was being decorated, almost the only trace of his handiwork being the staircase. Even the doors opening towards the oak staircase are only oak on one side, and white Louis Quinze on the other. After the interiors, whether of old work or modern, seen at Broadway, the inside of Nether Swell set our teeth on edge. Perhaps we were unfortunate to be seated at luncheon opposite the fireplace of the dining-room, where an elaborate composition in grey plaster reaching to the ceiling surmounts a delicately sculptured white marble mantle enclosing a deep recess lined with the crudest and roughest of red brick, with wide mortar joints and fitted with a modern dog-grate. We could not help thinking what an opportunity has been missed for a real English interior on Jacobean lines, such as may be seen at Chastleton or Sudeley. What could have induced the owner of this fine house—externally—to go to Paris for his internal decoration, when such examples exist within the distance of a short drive, we cannot imagine.

Good as was the material refreshment at Nether Swell the artistic delight of Chastleton, at which the members completed their day's programme, was far better. Here is an interior that should be good to live with, as it was pleasant to study for all too short a time. A charming hall and stair leading on the first floor to a wonderful old dining-room, with splendidly carved panelling, full of a curious combination of refinement and coarseness in detail that conclusively proves that the craftsmen were to a large extent the designers of the work they executed, each expressing his own individuality. Chastleton is a house in which to study for a month, rather than to scamper through in an hour. From Chastleton the party drove to Moreton-in-the-Marsh station, and so by rail to Cheltenham.

Friday, the last full day, gave the excursionists their first relief from the blazing sun that seemed bent upon concentrating the whole of our belated summer into a single week, and clouds, with an occasional burst of sunshine, tempered the great heat. By rail again the party went to Winchcombe, and then drove up to the high-lying manor-house and chapel at Postlip. The house is clearly of at least two distinct periods, the eastern wing, with a gable on the south and a row of dormers on the east side being of Tudor date, and the extension westward with four more gables on the south or entrance front, of the early seventeenth century, probably of about the date carved on the fine dining-room chimney-piece—1614. This extension, which forms the greater part of the existing house, is said to have been the work of Giles, of Broadway. There is a good chimney-piece in the hall also, but the finest room of all is that over the dining-room, which not only has a magnificent chimney-piece, but is

Digitized by Google

FRONT ELEVATION, PAVILIONS FLANKING ENTRANCE, INTERNATIONAL EXHIBITION, BUENOS AYRES.

panelled throughout with carved frieze and pilasters. A charming feature of the house is an internal courtyard in the centre of which is a fountain.

From Postlip the excursionists drove back to Winchcombe, where after luncheon a pleasant hour was spent in sketching some of the old houses and parts of the church.

Winchcombe is a market town of great antiquity, and in the past of great importance, for it was at one time a county of itself, until, in the days of CANUTE, his viceroy, EDRIC, "joined the Sheriffdom of Winchelscomb, which was entire within itself, to the county of Gloucester." During the Heptarchy it was the residence of some of the kings of Mercia, of whom OFFA founded a nunnery here in 787. In 798 CENULPH, who succeeded to the kingdom of Mercia after the death of EGFERT, OFFA'S son, laid the foundation of a Benedictine abbey for three hundred monks, and dedicated it to the Blessed Virgin MARY. This abbey gradually fell into the hands of secular priests until 985, when OSWALD, Bishop of Worcester, reformed its discipline, recovered the lands of which it had been deprived, and restored it to the Benedictines, who, despite some ups and downs, maintained a high position under a mitred abbot until the dissolution of monasteries. Now all trace appears to have been lost of its establishment except the traditional site.

Amongst the sources of wealth of Winchcombe in the past was the cultivation of tobacco, which is said to have been first planted here after its introduction in 1583. This industry was crippled by the restrictions on the trade introduced in the twelfth year of CHARLES I., which seems to mark the commencement of the decline of Winchcombe, judging from the remains of ancient architecture.

The parish church, partly erected by Abbot WILLIAM in the reign of HENRY VI., and completed at the expense of the parishioners with the assistance of RALPH BOTELER, Lord of Sudeley, is a fine example of Perpendicular work, especially notable for its bold detail and great gargoyles.

From Winchcombe a short drive through the park of Sudeley brought the party to Sudeley Castle, where they were met by the owner, Mr. DENT-BROCKLEHURST, who acted as cicerone to the marvellous collection of historical treasures with which the house is crammed, dating especially to the periods of the Tudors and the Stuarts, with whose fortunes the then owners were so closely connected. These do not, indeed, comprise all the relics of the past, for there is at Sudeley a quite remarkable collection of neolithic arrow-heads, celts, and other implements; and the contents of this remarkable private museum include many stirring records of English history from prehistoric times down to the mementoes of the late General GORDON.

Sudeley manor-house or castle was built by RALPH BOTELER, a famous admiral in the reigns of HENRY V. and HENRY VI., from the spoils gathered from the French navy. He sold it to EDWARD VI., to avoid confiscation, and that monarch granted it to Lord SEYMOUR, who afterwards married Queen CATHERINE PARR, the widow of HENRY VIII., for whose reception considerable additions were made. In ELIZABETH'S time, that queen was entertained at Sudeley in 1592 by the third Lord CHANDOS, and apparently about that time further additions were made. The castle being held by GEORGE, Lord CHANDOS, for the King in the Parliamentary war, was twice besieged, and although the artillery seem to have done little damage, a great portion was destroyed by the Parliamentarians after their capture. The ruins that they left give evidence that the design of the architectural work they destroyed was of a high character.

From Sudeley Castle the excursionists returned by rail from Winchcombe station to Cheltenham, and in the evening was held the usual meeting for display of sketch-books, for election of the excursion committee, and for music that constitutes the virtual wind-up of an A.A. excursion; but on Saturday morning a visit was paid by about half the members to the shops of Messrs. H. H. MARTYN & Co., LTD., where the bulk of the work in hand

at present appeared to be in execution of designs by three of the regular attendants at the A.A. excursions—Mr. A. W. Prentice, Mr. G. H. Fellowes Prynne, and Mr. C. E. Bateman. The actual operations of high-class ornamental work in plastering, woodwork, carving, sculpture, and metal-work were seen by and explained to the visitors.

Thus ended a really enjoyable excursion, differing in one respect from all others but one of the preceding thirty-nine, as far as memory of the oldest attendant went—that of being rainless.

NOTES AND COMMENTS.

The competition for a new town hall at Stoke-upon-Trent looks like becoming a cause of heart-burning and wrangling on the same score as that for Middlesbrough public library—disregard of the conditions. As we report in another column, Mr. Leonard Stokes, the assessor, has selected the best three designs. Of these clearly the first and third considerably exceed the stipulated cost. Clause 15 of the conditions of competition reads:—"Any design adjudged to be likely materially to exceed the sum of 25,000*l.* on the buildings, exclusive of furniture, fittings, &c., will be disqualified, but in this sum 1,000*l.* must be included for an organ." This is quite clear and definite; there is no doubt about the meaning of "will be disqualified," and the assessor's obvious duty was to disqualify every design that infringed this condition, even if all were so disqualified. In the questions by competitors there was included the inquiry as to whether "the usual 10 per cent." margin on cost would be allowed, and the reply was "Am unable to add anything to the conditions already supplied to you with regard to the cost of the building." It was therefore made perfectly clear that the condition as to cost was "of the essence of the contract," as the lawyers say, and it is no answer to urge that the accommodation required could not be provided for the stipulated sum. The Council are therefore in our opinion quite right in adopting the recommendation of their committee to give the premium of 100*l.* to the design placed second by the assessor, and to insist on the disqualification of the others in accordance with the conditions.

It is high time that the Council of the Royal Institute of British Architects should decide whether assessors appointed by themselves or by the President are or are not to be expected to carry out their duties in accordance with the "Regulations for Architectural Competitions, approved by the Royal Institute of British Architects." We have had too many object lessons this year of an undesirable kind. Reading—the conditions drawn up by or with the co-operation of the assessor nominated by the President of the Royal Institute of British Architects. Naturally everyone thought they would be all right, and over 200 architects sent in their guineas for particulars. Then when designs were well under way, the competition is barred by the Royal Institute till the conditions are modified. Middlesbrough—the assessor again selected by the President of the Royal Institute of British Architects. Conditions of the competition, admittedly ridiculous, ignored by the assessor and successful competitors. Now Stoke-upon-Trent—cost a vital element, and the assessor ignores an absolutely precise and definite condition of the competition, and, as far as our information goes, awards prizes to designs that ought to have been disqualified. It may have been, as it ought to have been, that Mr. Stokes in his report said, virtually, "These are the best three designs, but under clause 15 of the conditions Nos. 1 and 3 are disqualified."

The death of Dean Lefroy removes from amongst us a remarkable personality, and one to whom both the Church of England and the lovers of our ancient architecture must ever look back with gratitude for the work he did at Norwich, the restoration of the interior of the cathedral and of the cloisters, the magnificent organ, and above all the extended use of and interest in their cathedral church that he induced in the people of Norwich.

An important point in compensation law was established by the decision in the Manchester County Court in the case of Harry Lees *v.* Waring & Gillow, Ltd. Plaintiff, a painter, had become incapacitated by lead poisoning caused by the character of his employment, and the point was that Messrs. Waring & Gillow, whilst admitting liability, claimed that their liability should be shared by Messrs. James Ferguson & Co., in whose employment the plaintiff had been during a part of the twelve months previous to his incapacity. It was held by the judge that both of the plaintiff's employers should pay the compensation allowance, and that their shares should be in proportion to the length of time during the twelve months before incapacity that the plaintiff had worked for each respectively.

COMPETITION DRAWINGS FOR MUNICIPAL BUILDINGS, BURSLEM.

The subject of this competition is the provision for Burslem of facilities for amusement and the administration of justice. For the former a concert-room to hold 2,000, exclusive of the stage, and an assembly-room for 400, exclusive of the platform, were to be included, provision being made for the service of banquets in the assembly-room and for dramatic performances in the concert-room. For legal purposes a police court, a borough court, and a children's court were to be provided, with the necessary retiring rooms, &c., for those engaged in the business of the courts. The cost was limited to 25,000*l.*, with a 10 per cent. margin. The site is an irregular trapezium, almost square, with a principal frontage of 197 feet to Wedgwood Place on the west, a frontage at the rear on the east to Price Street of 175 feet, a frontage of 140 feet to a cross street, Jenkins Street, on the north, whilst the remaining south side of 159 feet adjoins the Post Office. The frontage to Wedgwood Place falls 11 feet 3 inches from north to south, and that to Price Street 8 feet 6 inches in the same direction, the cross street being practically level. The site, as the competitive designs show, is none too large for the accommodation to be provided, and the limit of cost does not allow of extravagance.

Twenty-three designs were submitted, and the assessor, Mr. Henry T. Hare, placed first that of Messrs. Russell & Cooper, whose prize is the job, whilst Mr. E. M. Thomas obtains the second place with a premium of 100*l.*, and Messrs. Warwick & Hall, the third with a 50*l.* premium. Messrs. Russell & Cooper have placed their building squarely on the site, and arranged a symmetrical front to each thoroughfare. By so doing they leave an open space between their building and the Post Office, enabling them to obtain from this space three separate entrances for the courts—one in centre for the public, one for children, and one for the police. Then, on the main frontage, that to Wedgwood Place, they are able to get the entrances to the concert hall, which occupies the central portion of their building on the principal axial line. Taking advantage of the fall of the ground, they have been able to arrange two entrances to the gallery of the concert hall, and a magistrates' entrance under one of the gallery stairs. The artistes' entrances are in Prince Street, and also that to the scene store and dock, whilst the entrance to the smaller assembly hall is in the centre of the Jenkins Street frontage.

The large concert hall, being in the middle of the site, has symmetrically, on the south of it, the two courts back to back, and on the north the assembly hall. The concert hall has an internal corridor on each side, 7 feet wide, separated by piers only from the auditorium, and having over it part of the gallery, thus lessening the apparent projection of this. The hall seats 1,100 on the floor level, 583 in the main gallery, 180 in the back gallery and 120 in spring-up seats on the gallery walls—a total of 1,983.

The internal corridors of the hall lead to a crush hall, 94 feet by 9 feet, from which access is obtained to the cloak-rooms for gentlemen and ladies, each 27 feet by 20 feet. Two green-rooms are provided, one for the concert hall only, the other for either the concert hall or

Digitized by Google

the assembly hall. The kitchen and scullery to serve banquets in the assembly hall are on the lower ground floor below one of the cloak-rooms. The whole arrangement results in a simple and workable plan. The elevations are treated with great severity, as befits any building in a smoky manufacturing town like Burslem, but an admirable architectural effect is gained by a recessed portico of five bays with big Ionic columns and solid pavilions of slight projection at each end. Both practically and æsthetically the treatment of this portico is excellent.

Mr. E. M. Thomas, the author of the second premiated design, has adopted a similar principle in his plan to that of Messrs. Russell & Cooper—concert hall in the centre, assembly hall to the north and courts to the south. He has, however, left more space for entrance to the courts between his building and the Post Office, and so has been more cramped for room. There is consequently not the same directness and simplicity of plan that characterise the design placed first. Particularly in the disposition of the court department there is too much corridor and consequent maze-like plan. In Mr. Thomas's arrangement the entrance to the assembly hall is in Price Street, busier and therefore less quiet than Jenkins Street, which is a short cross thoroughfare. In this design there is also the treatment of recessed colonnaded portico that we find in the winning one. It is, however, less important, and being brought forward in front of the main wall cuts off the lower part of the windows above, which with their pediments and columns are an integral portion of the elevation. The treatment of the detail is of a more elaborate and ornate character than is Messrs. Russell & Cooper's, and hence not so suited to Burslem.

Messrs. Warwick & Hall's plan is quite distinct in motif from either of their more successful competitors. They have placed the concert hall on the north side of the site with its crush hall and entrances towards the cross thoroughfare Jenkins Street. The courts are then located on the south-west, and the assembly hall on the south-east portion of the site, which is fully occupied up to its limits. The entrance to the courts thus comes on the Wedgwood Place frontage, and that to the assembly hall on the Price Street front. There may be some logical reason for such a disposition, each of the three main divisions of the building being entered from a separate street and each distinctly differentiated and expressed in the architectural treatment of elevation and grouping. In the result, however, it must be said that Messrs. Warwick & Hall's scheme gives less accommodation in accessories, retiring-rooms, &c., than does that of Messrs. Russell & Cooper. We like the expressiveness and the treatment of the exterior, but this necessarily detracts from the dignity found in the winning design. As a matter of composition only we think Messrs. Warwick & Hall have erred in placing their lower buildings on the lower part of the site and their main and highest block at the upper level.

Messrs. Spier & Bevan have adopted in the main the disposition followed in the third premiated design, but have placed their entrance and crush hall to the concert hall on the Wedgwood Place frontage. Their plan has many good points, but their courts are small, the entrance to the assembly hall is not satisfactory and the accessories are meagre. Their elevations are worthy of a better plan and are of the modern municipal Renaissance character.

Messrs. Bailey & McConnal have designed an imposing but too costly building, and have crippled the planning of their concert hall by devoting too much space to their courts—a mistake made by several other competitors.

Messrs. Milne & Hepburn have started with an idea similar to that of the winners, but have reversed the position of the assembly hall and courts. The latter are small, and the details of the plan do not fit together well or give the accommodation that might have been obtained. The elevations are not good and sadly lack a sense of proportion.

Messrs. May & Perrin have their concert hall paraliel to and adjoining Price Street; their courts occupy the whole of the Wedgwood Place frontage and the assembly hall is in the middle of the site. The children's court was required to be small, but 20 feet by 18 feet is a bit too small. The elevations are simple and dignified.

Messrs. A. R. Wood & Son have designed a good exterior, not too ornate; but their plan has the courts and halls rather too much mixed up. Their concert hall is also rather too much of a theatre, as if they expected the "variety" or music-hall form of concert, which, we understand, falls in with the views of the Town Council.

Mr. J. B. Fulton is one of those who has placed his concert hall on the east side of the site, but he has kept his building rectangular and symmetrical. The assembly-room is at the S.W. angle on a lower level than the concert hall. The plan is a good one in the main, but a disproportionate part of the site is occupied by the courts, which have more than their share of corridors and entrance halls. Mr. Fulton's perspective is of the interior of the entrance hall to law courts, a good drawing and a well-designed feature of the plan.

Messrs. Wills & Anderson have, so to speak, adopted Mr. Fulton's idea reversed—the concert hall to Wedgwood Place, the courts to Price Street, and the assembly-hall in the S.E. instead of S.W. corner, and, like Mr. Fulton, they have devoted too much area to the courts. Their elevations are eminently simple and dignified.

Mr. A. Hessell Tiltman has the same general disposition as Mr. Fulton with the same ultra-importance in plan of the courts. He proposes a lofty tower as part of his design, and places it in the short cross street.

There can be no question as to the superiority of the plan of the winning design, and it is adaptable for the uses intended by the Town Council, although it is not so obviously in accord with the methods by which those functions were expected to be possible.

INTERNATIONAL EXHIBITION AT BUENOS AYRES.

To commemorate the first centenary of Argentine Independence the National Government is organising an International Exhibition of Railway and Land Transport, which will be open at Buenos Ayres from May to November next year. The exhibition will occupy an area of 180,000 square metres, one-half of this area being intended for structures and the other half for streets, gardens and other ornamental accessories. As an example of the architectural treatment adopted we illustrate the designs for some of the more important buildings.

ARCHITECTURAL REFINEMENTS IN MEDIÆVAL CHURCHES COMPUTED.

Professor William H. Goodyear has called our attention to an article in this month's *Architectural Record* by Professor Hastings, which is collateral evidence corroborative of Professor Goodyear's view that in Mediæval buildings there are variations from the obvious hard-and-fast setting out that might be expected, and that, whatever their reason, æsthetic or otherwise, these variations are intentional and not accidental. Professor Goodyear says concerning the article—which we reprint—by Professor Charles S. Hastings, professor of physics in the Sheffield Scientific School at Yale University:—"Professor Hastings is one of the most distinguished members of the Yale faculty. He is the author of a book on physics and also of a book on optics, and is also the inventor of a magnifying lens which is named after him the Hastings lens, and which is manufactured and sold by Bausch & Lomb, the most important manufacturers of lenses in this country. It will hardly be necessary for me to mention the attainments and capacity of Professor Hastings in optics and in mathematics after the article is read, and in his capacity of professor of physics in a technical school of practical engineering he is also an expert on thrusts and strains. It will be found that Professor Hastings's article is mainly concerned with the Church of St. Ouen at Rouen. Although I do not wish to obtrude my own personality into the consideration of Professor Hastings's article, it is still a

Digitized by Google

matter of interest that after I examined this church in 1903 I described it in two publications as having strictly perpendicular piers. In 1907 I was led to re-examine this church, and was astonished to find that the piers diverged in straight lines, beginning at the pavement, 6½ to 7 inches to a side. This measurement was estimated on a surveyor's disc of rather small dimensions in the photograph, and could not be considered as a closely accurate measurement. It will be found, however, that this estimate corresponds within a third of an inch to the estimate made by much more accurate methods which is published by Professor Hastings. It is not at all important to dwell on the correspondences of measurements as between my own measures and those of Professor Hastings at Rheims, especially as the surveyor's disc in the nave at Rheims was of unusually small size in the photograph, and it is difficult to make an accurate compass estimate on such a disc. However, I will mention as a matter of possible interest that my estimated measurement for the divergence of the north side pier at Rheims, which is numbered four in Professor Hastings's table, was 10 inches; 2 inches of this estimate are accounted for by an off-set or stepping back of the vaulting shaft just above the capital, so that my estimated inclination was 8 inches. Professor Hastings's estimated inclination on the same pier was 0.677, which is $8\frac{1}{8}$ inches. In other words, our estimates at Rheims corresponded to the sixteenth of an inch. As I have said, I do not wish to lay any stress at present on these correspondences, as Professor Hastings's measurements are scientific and mine are empirical. What I wish to point out is that the widening refinement in the Church of St. Ouen has been demonstrated to exist by a professor of physics who has astonishing mastery of engineering, of optics and of mathematics. This demonstration is based upon methods and the use of instruments which are hardly understood except by astronomers and by scholars in physics":—

It has long been known that many of the great Mediæval Gothic monuments of northern Europe do not follow simple geometrical forms, either in their plans or in their elements of construction. Such features have been largely ignored by writers on Gothic architecture, or, if noted at all, have been treated as evidences of either originally defective construction or as proofs that the edifices have, since their erection, suffered deformations by yielding of their supports or foundations. Professor William H. Goodyear has been convinced, from his studies, that many of these deviations from geometrical simplicity have not only existed from the beginning, but were consciously introduced by the architects as essential parts of their designs. He has attempted to establish his theories by an assiduous collection of requisite data from such of these monuments as his time and the laborious nature of the necessary measurements permitted; he has displayed the results of these investigations in lectures and in printed papers of extraordinary interest. And, indeed, if his views are correct, their importance can hardly be overestimated; for they mean that this kind of rational, purposeful deviation from geometrical simplicity is an essential feature of Gothic architecture; remove it entirely, and whatever may remain it is *not* that architecture which is the glory of the twelfth, thirteenth, and fourteenth centuries in Europe.

The task which meets the investigator in this field is to prove that the admitted departures from geometrical simplicity are in no sense irregularities, since they lack the element of fortuity; to demonstrate that the haphazard character, which alone reduces them to the realm of accident, is wanting. Mr. Goodyear's method has been to select a large number of examples illustrative of the characters in question, to show their departures from simple regularity by photographs which contain proper reference lines, such as plumb lines or the like, so arranged that not only is the fact strikingly evident, but every examiner of his photographs can find the quantity which is the true measure of the deviation, and then, by a study of the nature of the masonry, demonstrate that supposed yielding subsequent to the erection is absolutely untenable as an explanation. In addition, the strongest support for his views is found in the extraordinary adjustments shown in the minor features of the structures which are indisputably contemporaneous with the building of the more organic members, such as the wall openings and the inclinations of jambs and of mullions, of which he has collected an astonishingly rich store. He has thus founded an irrefragable argument in support of the belief that these features, so strangely neglected by writers on the history of architecture, are the objects of intelligent design and should be classed as architectural refinements. Nor is it possible for any physicist or engineer who has examined the evidence in Mr. Goodyear's possession to entertain for a moment a theory which accounts for the peculiarities by movements in the building subsequent to its erection; there is not only no stone which could suffer the strains implied and maintain its integrity, but there is no material known of such physical properties that it could under any kind of stress produced by weight suffer the kind of deformations that this theory postulates.

There is, however, an entirely independent method of arriving at the truth in a question of this kind. Suppose that we should make a careful study of any architectural monument of the Middle Ages and measure all the deviations from geometrical simplicity; from such a collection of measurements we could, by methods familiar to physicists and to astronomers, find a definite value to serve as a measure of the accidental errors of our measurements and also a definite measure of the fortuitous element of the structure itself. Again, suppose that after allowing for the effects of these elements of chance that there remained a residue which was obviously systematic, that is, which could be described in simple and unambiguous language. Under such circumstances one would say that the deviations were subject to law, and all the rules of logic would compel us to the conclusion that the deviations were the result of intelligent design. Our attitude might be exemplified by that of a traveller in a desert, uninhabited region, whose attention was attracted to numerous irregularities on the surface of the hillsides which, following all the larger unevenesses of the ground, still exhibited carefully adjusted slopes, never reversed in direction. Such a traveller would inevitably conclude, however faint and ruinous these remains now are, that he had here the evidence of the former existence of inhabitants who were familiar with the art of artificial irrigation. So in this field a discoverer of a definite *system* of variations from normal simplicity can infer the previous existence of design without troubling himself at all either as to the motives which stimulated the design nor as to whether the end sought by the designer was attained or not. It is by such methods and by such reasoning that I hope to add to the material and to the conclusions which are so closely identified with Professor Goodyear.

Until recently my own knowledge of the architectural refinements in Gothic mediæval churches was confined to the expedients of building the great divisions of the church on unconformable axes and the curving of the vaulting shafts; thus, when I failed to find the latter peculiarity in St. Ouen, it seemed to me that the upward widening of the nave, which is so easily detected in Notre Dame, was there absent. This error was corrected only when Mr. Goodyear gave a lecture at this university early in the current term; then for the first time did I learn of his discovery of widening with rectilinear vaulting shafts. Shortly after I found a number of negatives which my daughter had made in 1901 and which seemed adapted for study. These were (a) a negative taken from the back of the choir in St. Ouen at the level of the triforium gallery, and approximately eight feet from the line of the north wall; (b) a second one, taken from the same gallery, about seven feet north of the line of the other wall; (c) and (d) from the north and south ends, respectively, of the transepts at the same level; and, finally, (e) a negative, taken from the gallery at the level of the bottoms of the clerestory windows at the west end of the cathedral at Rheims. It is the results from the studies of these negatives which is the subject of these notes.

Before describing the methods of measurement, it is well to consider the quite obvious objection which may be urged that the photographs are not sufficiently reliable representations of the subjects for the delicate uses to which we are to put them. It is true that all photographic reproductions are subject to errors, but an analysis of the objection shows that we have only two classes of errors to fear. The first is the perspective convergence of parallel lines, and the second is the more or less inevitable distortion of the optical images. The first error entirely disappears if the plate is perfectly parallel to the system of lines whose mutual inclinations are sought from the plate; that is to say, in the case of vertical spreads, if the plate was accurately vertical. But even if there were an error of adjustment of this sort it would introduce divergencies of such a simple type that they could readily be eliminated from the measurements. An example of the way in which this may be done will appear in the discussion of the variation of the nave width. In this series of negatives no perspective divergence of the vertical members of the structure could be detected, and we must suppose that the plate was essentially vertical. The camera was provided with a level.

Digitized by Google

The error of distortion appears as a continuous change in the linear scale of the image with the distance from the centre of the plate. Practically it is always an increase, so that the effect is to exhibit the image of a rectangular network with all its lines, except those which pass through the centre, as curved lines, convex inward. In so-called rectilinear camera lenses this error is very small, so that the curvatures introduced optically are wholly inappreciable to the eye; but in an investigation as delicate as that which here occupies us, it would not do at all to rely upon the condition of rectilinearity being perfectly attained by any optician, however skilful. Fortunately, the geometrical character of the errors is of such a nature that we can readily escape being misled by them through a properly devised method of measurement. It is obvious, from the description of the kind of distortion to which photographs are subject, first, that all straight lines passing through the centre of the picture remain straight in the photograph; and, second, that all lines nearly at right angles to a straight line through the centre preserve unaltered their inclinations to each other in the region near the diametral line. Hence, for example, if we are attempting to measure small deviations from the vertical of a system of lines, we cannot be misled by errors of distortion in the picture if the observations are confined to portions of the system near a horizontal line passing through the centre of the plate. In the following measures the indicated precautions were carefully observed.

In order to determine angles the negatives were successively placed on the circle of a dividing machine, which was mounted upon ways. Above the negative was stretched a fine wire. By a proper turning of the circle and shifting on the ways any line of the negative could be brought under the wire and a coincidence secured with great accuracy. Thus examined, the first negative (a), which was taken from a point in the triforium gallery, about seven feet north of the axis of the church, showed a mean divergence of the piers on the opposite sides of the nave of 45.8 minutes of arc, with an indicated uncertainty of 0.7 of a minute.* Similar measurements of the second negative (b), taken at about eight feet south of the axis, gave 46.7 minutes, with an indicated uncertainty of 1.3 minutes; from the two values I deduce a spread of 46.1 minutes, as the best attainable, with an indicated uncertainty of 0.8 of a minute.

The final value may be expressed in more familiar terms if we reduce it to linear feet. Adopting the height of the line of springing of the vault arches above the pavement as equal to 78.7 feet (Viollet-le-Duc), this corresponds to a spread of 1.055 feet in the nave.

Similar measurements on the negatives of the transepts gave 16.9 minutes and 16.1 minutes respectively. A reduction of the mean of these two values gives 0.378 feet for the spread of the transept. The disparity of these two spreads seemed somewhat surprising, but it occurred to me that it might have some relation to the relative lengths of the two colonnades. The only plan of the church accessible to me is that contained in Fergusson's familiar work; this gives the ratio of the length of the church to its width as 2.71, while the ratio of the two divergencies which I found is 2.79. This agreement of ratios is most striking, and renders it difficult to escape the conviction that the architect fixed upon it for reasons of his own. If we admit design it presents us with one of the most delicate refinements yet noted.

In the measures of angles there was no certain indication of fortuitous differences; but there is strong evidence that such accidental errors, if as great as one-fiftieth of the total divergence in the nave, would have hardly escaped detection.

After the inclinations were measured, the negative (a) was placed on a comparator and the absolute separation of the images of the inner faces of the piers was determined. It was also found that the ratio of the width of the nave at each pier to the height from the pavement to the springing line of the vault was constant. This was found to be 0.386, with an uncertainty of one-five hundredth of the whole value. In order to interpret the measures it is necessary to have some dimensions given in known terms. Fortunately, I have three such standards at command: first, the plan drawn to the scale of 100 feet to the inch in the well-known work of Fergusson; second, the elevation of a bay of this church, with attached scale, in the dictionary of Viollet-le-Duc; and, third, the known focal length of the camera with which the negatives were made, namely, 15.0 centimetres. Anyone of these data would yield values for the real dimensions of the measured features of the nave, and such derivations from each should agree with those from the others within the limits of errors which we are forced to ascribe to the data themselves. It may be stated at once that, since a careful study failed to detect any significant errors in any one of these quantities, as compared to the others, we may have a corresponding enhanced confidence in the results.

These data, with my measurements and some obvious deductions, are contained in the accompanying table. I arbitrarily assume that the pier height, given above from Viollet-le-Duc, is that of the fifth pier from the crossing; hence, from my determination of the ratio of width to height, the width of the nave at this point is 30.41 feet.

Table 1.*

Pier.	D.	N.	S.	w.	W.	W'.
1	162·0	—	−2·054	—	—	30·87
2	182·7	+0·716	−1·808	2·524	30·76	30·76
3	203·4	+0·653	−1·601	2·254	30·58	30·64
4	224·1	+0·601	−1·440	2·041	30·51	30·52
5	244·8	+0·556	−1·306	1·862	30·41	30·41
6	265·5	+0·506	−1·200	1·706	30·21	30·30
7	286·2	+0·460	−1·122	1·582	30·21	30·18
8	306·9	+0·419	−1·052	1·471	30·11	30·06
9	327·6	+0·380	−0·990	1·370	29·94	29·95

Here D is the distance in feet from the position of the camera to the planes of the several piers as derived from Fergusson; N and S are, respectively, the micrometrically measured distances from the vanishing point of east and west parallel lines in negative (a) to the several piers on the north and south sides of the nave, expressed in centimeters; and W are the corresponding apparent widths in the same unit of length. Pier 1, on the north side, is hidden by the crossing pier, and hence does not appear in the last-named column.

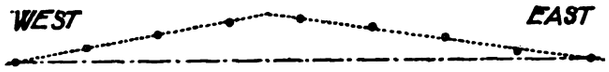
A casual inspection shows that the products of D by W are not constant throughout the table, as they should be if the apparent convergence in the picture were due to perspective alone; but instead of being constant they continuously diminish with increasing D. To test this, I have multiplied each of the products by a number which will yield our arbitrarily assumed width of 30.41 feet at pier 5, and entered the results in the column headed W. Clearly, there is a narrowing towards the west. If we assume a total narrowing of 0.92 of a foot from pier 1 to pier 9, equally distributed through the eight bays, we have the numbers given in column W'; the differences between W and W' afford a measure of the precision of the construction. These differences indicate an uncertainty in the width of only 0.03 a foot, which obviously includes the real errors of the structure and my own errors of measurement. Of course, in view of the established constancy of the ratio of height to width, this means that the vault also is lowered towards the west.

This wholly unlooked-for discovery prompts the question as to whether the conclusion can be avoided by any modification of one or more of the fundamental constants upon which it rests. A serious investigation from this standpoint has been unfruitful, hence I am obliged to assert my belief in the reality of the feature.

An inspection of either of the photographs (a) or (b) shows that the axis of the nave is not a straight line; it seems to be a delicate curve of long radius convex northward. The above table enables us easily to test this impression. After finding from the negative (b) that the first pier on the north side is 0.120 of a foot south of the line joining the second and ninth piers, I find, by a calculation the nature of which is almost obvious and need not detain us here, the offsets of the individual piers on each side as given in the accompanying table:—

Table 2.

Pier.	N.	S.	Mean.	Calc.
1	0·000	0·000	0·000	0·000
2	0·120	0·110	0·115	0·152
3	0·296	0·350	0·323	0·304
4	0·455	0·482	0·468	0·452
5	0·598	0·614	0·606	0·604
6	0·528	0·590	0·559	0·583
7	0·390	0·372	0·381	0·389
8	0·229	0·173	0·201	0·194
9	0·000	0·000	0·000	0·000



Here N and S are the offsets for each pier in fractions of a foot from the line joining the first and ninth on each side, in every case to the north. The next column is the mean of the two which may be taken as a determination of the deviation of the axis of the nave from a straight line joining the

* This is the numerical value of the probable error deduced from the group of measures. This explanation will render my meaning perfectly clear to those familiar with the theory of errors.

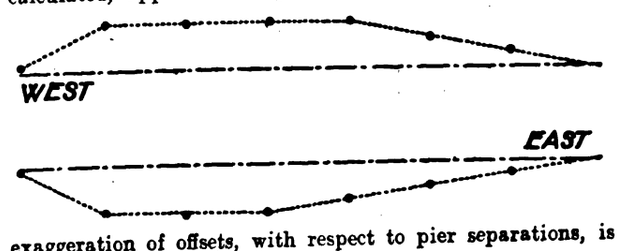
* This table has been given in full because anyone by means of it can test independently my conclusions either by calculation or by construction on the drawing-board.

Digitized by Google

point midway between the first piers, north and south, and the corresponding point between the ninth pier. The accompanying figure (Fig. 1) exhibits the deviations greatly magnified, the scale being twenty times as large in the north-

south direction as in the east-west direction. The dots in the small circles represent the quantities in the fourth column of the table. It is at once evident that the points do not lie on a curve, but very nearly on two straight lines, represented as dotted lines in the figure, which intersect in the middle of the sixth bay. The agreement with this supposition is strikingly accurate; indeed, if 0.680 foot be adopted as the offset of this point of intersection, and the values and the offsets at the various piers be calculated, we derive the figures of the last column, which may be directly compared with my measurements in the other columns.

The positions of the mid-points of the piers at the crossing are certainly very nearly on the same line as those of bays 1 to 5.



The material for a study of the construction of the cathedral at Rheims, consisting, as it does, of a single negative, is far less comprehensive than that of St. Ouen. Moreover, the position of the camera was not so favourable for our purposes. Its height was so great that the piers below the capitals of the great arcades cannot be studied, although we know from Professor Goodyear's observations that these piers are vertical. In the negative all the great piers at the crossing are well shown; on the south side eight of the vaulting shafts are well adapted for measurement, and on the north side seven. The measurements show readily that all of the crossing piers are parallel, and also, since there is a conveniently placed chandelier rope in the picture, that they are strictly vertical. The declinations from the vertical which follow were either determined from a crossing pier or from this rope hanging from the vault, whichever seemed the more convenient at the moment. As in St. Ouen, the vaulting shafts are rectilinear, but, unlike that example, they are not all parallel on either side. The shafts nearest the crossing are but slightly inclined outward, while the fourth, fifth, and sixth on each side have nearly similar inclinations; the seventh on each side again approaches closely the vertical. Viollet-le-Duc gives, for the distance from the capitals of the nave to those at the top of the vaulting shafts, about 52.5 feet; this constant yields with my measurements the leans for the shafts given in Table III. in the horizontal rows marked "Obs."

Table 3.

Pier—		1	2	3	4	5	6	7
North	Obs.	0·235	0·434	0·631	0·677	0·675	0·648	0·095
	Cal.	0·221	0·442	0·664	0·664	0·664	0·664	—
South	Obs.	0·163	0·342	0·490	0·653	0·683	0·648	0·053
	Cal.	0·141	0·282	0·423	0·664	0·664	0·664	—

It is evident that the leans on both north and south side for the piers 4 to 6, inclusive, are practically the same. If we assume that the mean of these measured values, namely, 0.664 feet, be that prescribed for this portion of the nave, we are forced to admit that the wonderful masons who built this cathedral could be relied upon to erect shafts with an uncertainty of inclination of less than 0.011 feet in a length of 50 feet. Such precision, if admitted, demonstrates a most curious fact: the builders of the north side of the nave made the change from the vertical position at the crossing piers to the normal lean of the nave in three steps, while those of the south side made the change in four steps. At least, this is the only interpretation of the measures which reduces the errors to the established limit as appears from the values in the lower lines, which are calculated on this theory.

A graphical representation of these offsets, observed and calculated, appears in Fig. 2, where the same twentyfold

exaggeration of offsets, with respect to pier separations, is followed as in the previous figure.

This is the only departure from geometrical simplicity in construction which I have found giving rise to a suspicion of a real error or mistake; at least, so capricious a variation from a definable system seems hard to understand otherwise. In any case, it is curious that such a singularity seems to have escaped observation hitherto for seven hundred years.

The conclusions in this paper, derived from a series of measurements of photographs, may be admitted to have great interest; but it seems to me that the true value of the investigation lies in two of its features. In the first place, it exhibits a method by means of which architectural monuments can be surveyed with an expenditure of effort incomparably less than that required for a thorough survey by direct measurements. The other feature, of perhaps still greater importance, is that, as far as known to me, it constitutes the first effort that has been made to determine the lower limit of precision which we ought to attribute to the mediæval masons. In any discussion as to the origin of the deviations from geometrical simplicity in these structures, this datum is clearly of the highest importance

ILLUSTRATIONS.

REBUILDING OF NETHER SWELL MANOR, GLOUCESTERSHIRE.

THIS building was one of those visited last week in the course of the annual excursion of the Architectural Association, and reference to it will be found on p. 113 in the leading article descriptive of the excursion to Cheltenham and district. Mr. E. Guy Dawber is the architect.

BOYS' SECONDARY SCHOOL FOR THE BOROUGH OF BROMLEY KENT.—DETAILS OF PRINCIPAL ENTRANCE.

THIS school, when completed, will accommodate 300 boys, but at present only a part of it, sufficient for 200, will be erected. The main frontage is placed 50 feet back from the line of Hayes Lane, and contains the principal entrance. There are two other entrances approached from Hayes Lane also—viz. that for the senior boys at the western side, and that for the juniors on the east. The style of the building is eighteenth-century, and is in character with the interesting buildings of old Bromley. With such an ample and open site a building of more than two storeys was judged to be uncalled for. The accommodation provided is indicated clearly on the plans and meets all the conditions imposed in the competition. The building consists of a central block, containing the central hall, class and lecture rooms, and the whole of the teaching portion of the school, while the eastern and western wings contain the dining-hall, gymnasium and auxiliary accommodation. The caretaker's house adjoins the east wing. The elevations are of brick with a careful use of Portland stone. The most ornate feature is the main-entrance doorway with walling above, the details of which are shown on our second plate. The plans were obtained by limited competition, as the result of which Mr. John Bilson, F.S.A., F.R.I.B.A., the assessor, selected that by Mr. H. P. Burke Downing, F.R.I.B.A., which is here illustrated.

THE "FILESMITHS' ARMS," SHEFFIELD.

THIS house was erected in 1906 for the owners, Messrs. Wm. Stones, Ltd., of Sheffield, and replaced an old and somewhat inconveniently arranged structure. The materials employed are dark salt-glazed bricks in the base with vitreous buff terra-cotta above; the panels over the ground-floor windows are of green faïence, and the letters are gilt. These materials and the general treatment of the building were adopted so as to permit frequent washing of the exterior. The terra-cotta was supplied and fixed by the Burmantofts Works of the Leeds Fireclay Company, Ltd. Messrs. H. Freckingham & Sons, Ltd., of Sheffield, were the general contractors, and Mr. James R. Wigfull, A.R.I.B.A., of Sheffield, was the architect.

SHOPS AND OFFICES, WAKEFIELD.

THESE premises have been recently erected in Market Place and Cross Square, Wakefield, on a triangular site. A separate entrance is provided from Market Place to the upper floors, which are to be let off as offices. The materials are grey terra-cotta, the roof being covered with green slates. The architect is Mr. Percy Robinson, F.R.I.B.A., Leeds.

FRONT ELEVATION, PAVILION FOR PUBLIC MEETINGS, INTERNATIONAL EXHIBITION, BUENOS AYRES.

THE INSTITUTION OF MUNICIPAL ENGINEERS AT DURHAM.

THE Institution of Municipal Engineers has just completed the first year of its existence, and, judging from the quality of the papers discussed at the various meetings held throughout the year, the success of the movement towards advancing the status of municipal engineers, and the number and character of its membership, it may unhesitatingly be said that the Institution has established for itself a leading place among engineering societies. The roll of the Institution at the end of the first year was 613—556 members and 57 students, and it stated that the total now reaches about 650. The annual meeting was held last week at Durham, of which city the President of the Institution, Mr. J. T. Pegge, is engineer and surveyor. It must be admitted that the attendance at this meeting was disappointing in the extreme, and the discussion upon the papers suffered considerably. The Mayor of Durham briefly welcomed the Institution, after which the main business of the meeting was proceeded with. Mr. Pegge, who took the chair, announced that the annual report, also the balance-sheet, would be taken as read. With regard to the finances of the Institution, it is to be noted that in spite of the heavy initial expenses in connection with the formation of the Institution, there was only a very small deficit, which, if all arrears of subscriptions were paid up, would be converted into a handsome surplus.

The first paper on the agenda was by Mr. Horace Boot, consulting engineer to the Tunbridge Wells Corporation, on "The Design and Requirements of Electric Power Works." This paper has already been printed in these columns, and readers will have noted that it afforded little scope for discussion or controversy, being in the main descriptive of how a station, especially a small station, should be designed and fitted. It was a pity that Mr. Boot could not attend the meeting in order to explain the essential features of his paper and to amplify it, while it is a still greater pity that no one present should have risen to deal with points of detail. The only contribution to the discussion was a written communication from Mr. Verrall, whose main point was whether in the event of a bulk supply being obtainable, it was worth the capital involved of constructing municipal works when very advantageous terms could be made involving the local authority only in the erection of transforming and distributing sub-stations and mains. In his opinion, therefore, the relative advantages of a private undertaking and a bulk supply should be carefully weighed up in the first consideration of an electrical supply undertaking. Of course, in cases of small isolated towns, where coal is expensive, and consequently generating costs very high, the practice advocated by Mr. Boot might find much favour, especially when the merits of the Diesel oil engine are considered. There is no doubt that in the near future a very large number of smaller towns will have under consideration the question of electricity undertakings, such as Chichester, to which Mr. Boot made reference in his paper, and it is unfortunate that he was not present to give more details of this scheme, as it seems probable that with the low first cost of buildings the capital might be kept very low, and, provided this type of plant is as economical as is claimed for it, very substantial results might follow.

The next paper on the agenda, "Municipal History and Works of a Small City," by Mr. Pegge, we print elsewhere. It is likely to appeal more strongly to the archæologist and to

Digitized by Google

the local historian rather than to the practical engineer, yet it serves to impress the spiritual and æsthetic aspects of the engineer's work, which the latter cannot afford to ignore. One cannot resist the impression on reading the paper of the remarkable improvement effected in local conditions during the past hundred years. It is also of interest to note how some of the problems which are prominently before us at the present day were dealt with in the distant past.

Mr. Pegge entertained the members to luncheon, after which a visit was paid to the main sewerage works, where the principal features were explained by Mr. Harry W. Taylor, the consulting engineer.

Later in the day the party visited the old castle built by William the Conqueror in 1070, and the ancient and historic cathedral.

REINFORCED CONCRETE.*

(Concluded from last week.)

Centring.

WITH reference to the design and erection of forms or centring for keeping the soft, wet concrete in place till it is properly set, there are two main conditions which must always be fulfilled. Firstly, it must be so supported and stayed that neither the weight of the concrete nor the ramming of it can make the centring bulge or sag; and, secondly, it must be as close-jointed as possible, otherwise the water will leak out and carry with it an appreciable amount of cement, which will weaken the structure. There are many methods of obtaining a smooth face on the finished concrete, such as painting the boards with oil or whitewash or any material to prevent the concrete adhering to them; but given fair flush joints in the woodwork, the passing of a thin piece of sheet steel (an old hand-saw with the teeth ground off is excellent for this purpose) between the concrete and the boards gives perhaps the best result whenever the general arrangement permits of its use. When work is to be floated or rendered, a rough surface is of course desirable.

The question of centring leads naturally to that of the length of time it should remain in place. The author is frequently asked to state his opinion on this in general, but no general or hard-and-fast rule is possible; on some jobs or portions of them twenty-four hours is ample, on others six weeks is too short. Much depends on the weather, particularly on frost, and much on the over-all scantlings of the various pieces, but, most of all and beyond everything, on experience; in fact, there is no material where experience on the part of the constructors is more important than in all matters connected with reinforced concrete, or where more disastrous consequences are likely to follow the lack of such experience. In this connection it is interesting to note the following extract from some remarks made by a gentleman who has done more than any other to place reinforced concrete on a firm basis—namely, Mr. William Dunn, F.R.I.B.A., who said in a paper which he recently read before the Concrete Institute and from which he has kindly given the author permission to quote:—

"Suppose, however, that the design has been carefully checked, initial difficulties got over and the work begun, the superintendence of the work is merely the transference of our anxieties into another field. I am very strongly of the opinion that no work of importance should be entrusted to men without experience; our best safeguard against defective work is undoubtedly the skill, experience and honesty of the contractor.

"No engineer or architect, unless he spends all his time during the execution of the work in actual and constant supervision, can secure his employer against dangerous errors on the part of the workman. In steel construction we can examine and measure every part after it is up; not so in reinforced concrete work. Once the concrete is laid we cannot tell, except by cutting into it, whether there are six 1-inch rods or two ½-inch rods inside a beam or pillar, or whether these are 2 inches or 4 inches from the surface. To see that the drawings are actually carried out requires a conscientious scrutiny and attention every minute of the time the work is being done. Much may be observed during a visit, but not everything.

"The number of skilled contractors, clerks of works and others constantly increases, and we shall soon all have had experience in this material. But with all the care possible there is a serious risk in employing an inexperienced contractor."

A contractor with considerable resources in the way of plant and materials is also very advisable. It is not long ago since a somewhat serious collapse occurred in a job where the concrete was put in on a Friday and the centring struck on the Monday, as the contractor had not, and could not get, any more timber.

Calculations.

Dealing with ordinary work, such as beams, walls and floors (which last can be regarded as beams for the purposes of calculation), the simple formula which has been in use by engineers during the past fifty years when calculating the strength of rectangular beams is eminently suitable for use in designing reinforced concrete. The author has made many calculations and tests to ascertain reliable values for the constant in that formula, which he hopes to be able to communicate at a later date, as also such for use with column and strut formulæ.

Standardisation.

The adoption of a series of constants in any set of calculations is useless unless the primary conditions governing the calculations are equal. For instance, the value of the constant just referred to is immaterial if the proportions of the concrete or the amount of reinforcement is altered, but these matters are becoming rapidly standardised, and if the proportions of one part of cement to two parts of sand and four parts of stone (this last all to pass ¾-inch mesh and refuse ⅛-inch) be adopted, the result need not be feared. This proportion may be also expressed for ordinary use—three 2-cwt. bags of cement, ½ cubic yard of sand and 1 cubic yard of stone, the mixture resulting in 1 cubic yard of concrete in place, as the sand and cement are only very little more than sufficient to fill the voids between the stones. This question of voids is important, because certain classes of stone lie much more closely together than others and it is therefore possible to economise in the purchase of sand, but this is entirely a matter for experience, as a glance at the mixing of the first batch will give more information than the most elaborate calculations.

As regards the percentage which the cross-sectional area of the reinforcement in tension is of the cross-sectional area of the beam or wall or floor, this varies between three-quarters of 1 to 2 per cent. but if 1½ per cent. is allowed for in ordinary work it is quite safe, and may be used as a standard for calculating quantities. Very frequently, however, both this matter and that of the proportions and ingredients above mentioned have little more than an academic interest for the general user. To take a very common illustration. A works manager decides to erect a travelling crane in one of his shops, and proceeds to order the rolled-steel joists to carry the wall-rails; he knows his loads and his spans, and that he can buy joists at so much per ton of such-and-such a section at such-and-such a weight per foot, which are guaranteed by some reputable steelmaker to carry the load required at the span decided upon (it must be remembered that we are not now considering any instance needing web or lattice girders, but strictly ordinary work only). He orders his joists without troubling about what proportion of carbon or silicon or anything else is contained therein, and the same procedure can frequently be adopted with regard to reinforced concrete, using the formula before mentioned or some other similar to find the scantlings, so as to get out the amounts of materials required in order to ascertain the cost. He, the works manager, may be quite certain that no reinforced concrete maker of repute will risk his name by putting in bad materials (or good materials wrongly disposed), any more than will the steelmaker with reference to the rolled-steel joists.

Methods of Using.

Reinforced concrete is now so largely and widely adopted that a list of even a portion of the various uses in which it has been already employed would extend to a great length. The following are a few remarks with reference to some of its better-known uses.

Buildings in General.

All buildings should be of skeleton framework construction. The spaces or panels between the columns and beams can be ⅛ inch filled in with reinforced concrete or with brickwork, or the whole frame covered with a skin of stone or brick; but as the main strength is in the frame, such panels can be quite thin, in fact only of such thickness as is needed for dryness, not for strength, which results in a large increase in floor area, particularly in the lower storeys, where otherwise the walls would have to be of considerable thickness.

Boats and Barges.

These have been successfully built for several years, and, provided several are ordered of one size—that is, made off the same moulds—they are very much cheaper than steel.

* A paper read at a meeting of the Institution of Mechanical Engineers at Liverpool by Mr. Arthur C. Auden, July 1909.

Digitized by Google

Chimneys.

From current quotations these certainly appear to be cheaper than the same in brickwork, and of course do not need pointing; but there may be a difficulty when one needs to be felled, as at present it is not known how to bring one down in a small area. It is, however, a simple matter if there is space available for the chimney to fall in one length.

Drain and Sewer Pipes.

Many miles of these have now been laid, and are giving great satisfaction both as regards first cost and upkeep. Great care is, however, necessary in their manufacture to ensure the reinforcement, both longitudinal and circular, being exactly in its correct position, otherwise there is a great risk of the sewage or water reaching some of the metal and the life of the pipes being therefore very short. One of the great advantages of reinforced concrete sewer pipes, particularly in bad ground—for instance, over old mine workings—is that they do not cost any more per yard when made in long lengths, up to, say, 18 feet if required; thus about 75 per cent. in the number of joints is saved, and they are able to carry the weight of themselves and contents over spans practically equal to their own lengths. The same remarks also apply to water pipes.

Dock, Retaining and Reservoir Walls.

The author has already noted the saving in space in buildings due to the use of reinforced concrete, and the illustrations in fig. 7 show that such is even more the case

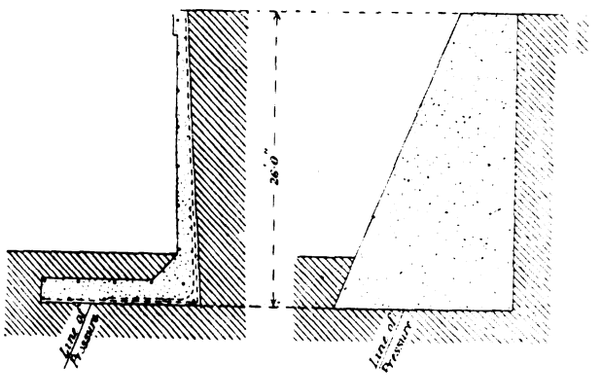

FIG. 7.

Comparison between amount of material required and useful space occupied in mass concrete and reinforced concrete dock or retaining walls.

with these walls, the one being in reinforced and the other in mass concrete. Both are drawn to the same scale, and calculated for the same strength with the same factor of safety.

Engine and Dynamo Beds.

Probably several of the members will remember the case of a large and important hotel in London having its own electric installation, where the vibration from its large turbo-alternator sets was a cause of serious complaint, notwithstanding the use of many different forms of soft anti-vibration materials beneath the beds. Finally reinforced concrete bed-plates were tried the same being practically replicas (in plan) of the cast-iron ones which rested on them, but only about 8 inches thick. These reinforced concrete bed-plates are very carefully reinforced and are only supported at points—that is, they do not rest directly on the old solid stone beds. The result has been very satisfactory, the difficulty of the vibration having been entirely eliminated.

Fence Posts.

The use of these is increasing very rapidly, but up to the present they are rather handicapped by the want of a cheaper method of attaching the wires to them, the ordinary hooks or staples being practically inadmissible, as they get bent and broken when the posts are bundled for carriage, and clips and bands or screw-plates are costly.

Magazines for Explosives, Safes and Strong Rooms.

Owing to its practically absolute fireproofness reinforced concrete is particularly suitable for these structures, and recent large and costly experiments in Germany have proved that even the explosion of huts containing 1½ to 2 tons of gelatine dynamite did no damage to their surroundings other than from the air-blast. It was found that the reinforcement was only rent but not scattered, and the concrete blown away in the form of coarse dust.

As regards safes and strong rooms it can only be said that, although a considerable number have been built, they are still awaiting an actual test at the hands of those skilled in the art of "safe-breaking."

Piles, Piers and Jetties.

One of the principal points to bear in mind when considering the use of reinforced concrete piles is that they will safely carry about three times the load of such in wood of the same cross-sectional area, also that they are no more difficult to drive; and, with reference to piers and jetties, the use of a material which does not deteriorate "'twixt wind and water" is a matter worthy of very careful consideration.

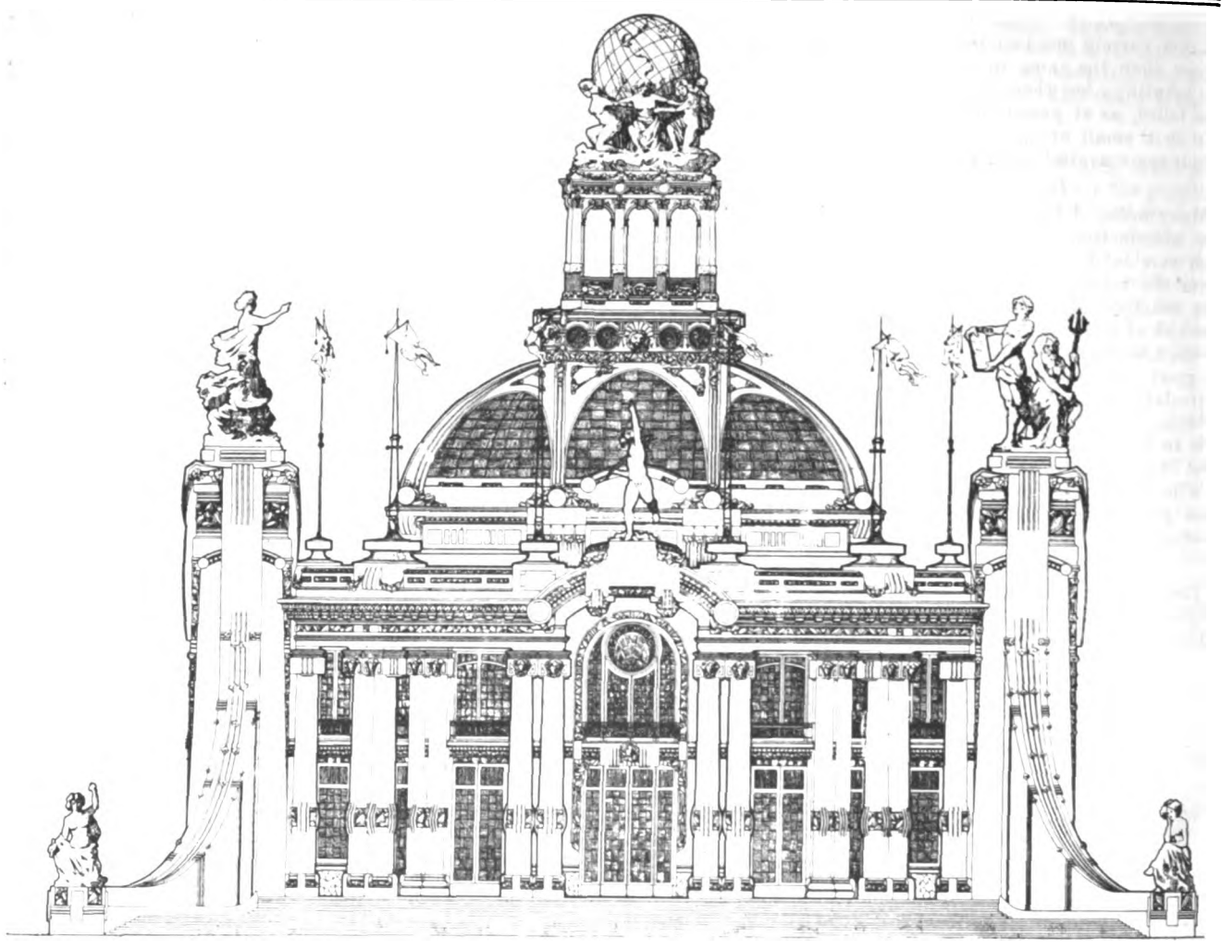
Pithead Gears and Pit Props.

These being fireproof is their strongest recommendation, and the latter, if made hollow, are, strength for strength, but very little heavier than ordinary wooden props.

Railway Sleepers.

As the most important question in relation to these is their life, not their strength, nothing but time will prove whether the use of reinforced concrete at a somewhat higher cost than wood will be the more economical in the end, but about five and a half to six years' experience of sleepers in continuous service under heavy traffic and rolling stock so far show no appreciable difference from the day they were laid down, and a recent order for over 100,000 of such shows that they are being extensively adopted.

Telegraph and Tramway Poles.



These are rapidly coming into favour, and very large numbers have been already erected. The fact of their not suffering from corrosion or rust, and therefore not needing painting, together with their being, at present quotations, considerably cheaper than steel, probably accounts for this demand. As they are tubular very great care is necessary in their manufacture so as to ensure that the reinforcement is absolutely accurate in position.

Painting.

The question of painting, although only now referred to, is one of vital importance with all reinforced concrete structures (other than buildings such as houses, offices, &c., which are usually plastered and papered), as it is well known that all naked steel and iron work deteriorates rapidly from rust and corrosion unless it is periodically very carefully scraped and painted. Even when this is done, the amount which is rightly deducted for depreciation in the case of a valuation for sale, transfer, mortgage or similar is very marked, in addition to the actual cost of such scraping and painting. This is particularly the case with bridges owing to their exposed position, and the expense of painting them is frequently considerably increased by the extra cost of the necessary cradling and scaffolding. All this is eliminated in the case of reinforced concrete, which increases in strength with age and is not subject to depreciation, nor are painting or scraping or other methods of preservation necessary. In fact, when comparing the cost of a reinforced concrete structure with that of a similar one in other materials, it is quite a good rule to work out the cost of the painting and upkeep, and, having capitalised the same at a rate per annum (say, 1 per cent. over the current Bank rate), to deduct this sum from the estimated cost of the reinforced concrete in order to place both propositions on an equal basis for purposes of comparison.

The author is fully aware that one of the very important questions relating to reinforced concrete from the users' point of view is that of the attitude regarding it of the various authorities, both those governing the country as a whole and those governing each municipal or county area. In some cases it is certainly true that serious restrictions have been placed on the use of this material, but these adverse views are rapidly decreasing, and it is only a question of time till they are eliminated altogether, in exactly the same way as the strenuous opposition to the use of iron and steel in buildings or in ships has now disappeared. With reference to municipal restrictions, in Liverpool they are more fortunate than in any other city in the kingdom within the author's knowledge, as each reinforced concrete proposal is considered solely on its merits. Not only must the plans be deposited as usual, but also all the calculations, which are carefully checked. If they prove satisfactory, permission is given to proceed with the structure as designed without any of the vexatious regulations, such as those regarding the thickness of walls, which are frequently enforced in other towns quite irrespective of what the said walls have to carry or the strength of the material of which they are composed.

MUNICIPAL HISTORY AND WORKS OF A SMALL CITY.*

THE history of any city of ancient note is more or less like that of other cities; but in the case of Durham with this difference, that until 1836 Durham city, as the capital of the palatinate of that name, was independent of the rest of the realm to a very great extent, and the Bishop of the See of Durham was its prince, and upheld these dignities in almost regal state, having his castles at Durham, Bishop Auckland, Bishop Middleham, Stockton, Craike and Howden (Yorks), Durham House at Durham Place in the Strand, London (now the Adelphi), and Norham Castle, on the borders of Scotland.

Durham city comprised four boroughs—Framwellgate, Gilesgate, the Barony of Elvet, and the Bailiwick, or city proper—being governed for nearly four centuries by a bailiff. About the year 1175—and history gives no record of earlier privileges enjoyed by the people of Durham—the first charter was granted to the citizens by the Bishop (Pudsey), and it was confirmed by the Pope at Rome. This charter was revoked in 1345, and in 1377 Bishop Hatfield granted to the burgesses and other good men in the city of Durham certain duties or tolls on divers merchandise or wares (of which a complete list is given) brought into the city, as an aid for defraying and supporting the pavements and the reparation of the walls of the city. In 1385 these powers, having been misapplied, were again called in. Between 1385 and 1565 the government of the city appears to have been retained in the hands of the Bishop, as a commission of inquiry was held in the fourteenth century, including among other things inquiry as to how certain moneys raised for paving had been spent. Then, about 1410, the Prior and Convent paid considerable sums for paving expenses, and it looks as though extensive public improvements were going on.

In 1450 Thomas Billingham, of Crook Hall (now within the north boundary of the city), conveyed to the burgesses a spring within the Manor of Sidgate, which supplied the pant or fountain in the market-place until 1850. The figure of Neptune in cast lead on the present pant was presented by G. Bowes in 1729. It may be interesting to note here that the bishops had their own mint, commenced in 1135 (King Stephen), and continued coining to about 1535—of which many specimens are extant. The coinage was mostly for poor relief purposes. This government by bailiffs nominated by the bishops continued until after the Reformation, when, in 1565, Bishop Pilkington, on January 30, granted a charter, whereby he ordered that the city of Durham and Framwellgate should be united, and appointed an alderman and twelve burgesses to be elected annually on October 4, who were empowered to publish laws and ordinances for the public benefit, to sue and be sued, and were granted a common seal, a weekly market, and three annual fairs, with power to hold a Court of Piepowder during the fairs. Their jurisdiction only extended over the parish of St. Nicholas and Framwellgate, excluding Milburngate. Crossgate was under the Prior and Convent, and had separate courts. Elvet was also under the Prior and Convent, and had a special charter from Prior Bertram about 1188, and the barony controlled beyond Court Lane (or Route en Roi). Gilesgate, or Gilligate, had its own government, grassmen, bakehouse, parish pound, and bull. These districts each had their own corn mills, worked by the river, at which the inhabitants were compelled to have their corn ground into flour. The charge was by "moulter," or one-sixteenth of the quantity taken for grinding. This was changed in 1822 into 6d. per bushel.

The granting of Pilkington's charter proved the commencement of an era of trade activity in the city. St. Nicholas Church became the official corporate place of worship, and the citizens evidently became proud of their municipal organisation, for in 1582 a townsman, Thomas Stout, left a drinking cup to the chief burgess, or alderman, inscribed "Yett God helpe," which is still in the possession of the Corporation. The city was governed by this charter, but it was found not to be sufficient for the growing trade and wealth of the city, and in 1602 Bishop Matthew granted the third charter, much more ample, by which the burgesses and inhabitants were constituted a body politic and corporate, consisting of mayor and twelve aldermen (for life) and commonalty, with divers privileges, liberties, free customs, with powers to make laws and regulations for the better government of the city. The 1602 charter appeared to consolidate and recognise the trades guilds, of which there were sixteen, most of whose coats-of-arms are hung on the walls

* A paper read at the annual general meeting of the Institution of Municipal Engineers, held at Durham on August 7, by John T. Pegge, President.

Digitized by Google

of the Guildhall. These trades guilds enabled the mayor, as head, to govern the areas then outside the borough proper, for the reason that each guild had its Master, who, by virtue of that office, was an "alderman" of the city, and there were two members of the following guilds on the Common Council:—Mercers, Drapers, Skinners, Cordwainers, Saddlers, Butchers, Smiths, Carpenters, Masons, Tanners, Weavers, Fullers, and Dyers. The Guildhall is still, strictly speaking, the Freemen's meeting-place, in which they claim prior rights to the Corporation. All the guilds had their own silver plate, which the wardens for the time being have, together with their records and books, in their private possession. It may be known to most of you that up to the beginning of the eighteenth century the whole of the tradesmen in the principal boroughs were "freemen," and had their trade "guilds," to which membership was obtained by (1) birth; (2) servitude; (3) purchase. Birth: In some trades the eldest son only, in others all sons. Servitude: Seven years' apprenticeship with a freeman, under a proper parchment agreement. Purchase: This was generally a stranger wishing to commence business, who was called on to pay a sum, varying from 20*l.* upwards, in order to entitle him to all the privileges of "frieledge." The common people were not members of these guilds, and were the representatives of the "serfs" of earlier times.

The guild coat-of-arms (hand-painted examples being hung in the Durham Guildhall) of the several companies appear to be like those of London, York, and other ancient towns, but the grouping of the various trades forming a guild is very peculiar. The records of these guilds are still to some extent existent, and the massed plate of the Corporation and guilds makes a show that many a much more important centre of to-day would give worlds to possess.

In 1603 Letters Patent were issued appointing a Recorder. In 1606 a silver seal, still in existence, was presented by Matthew Pattison, the descendant of one of the original burgesses. Trade must have been looking up, for in 1617 the Market Cross, having twelve stone pillars, was built by Thomas Emmerson. This was removed in 1780, and re-erected to form the first attempt at a covered market, known as the "Piazzas," in the market-place along the south side of St. Nicholas Church. In 1621 a silver bowl was presented. In 1630 two large five-quart flagons were presented by Alderman Whitfield. In 1638 the sword and mace-bearers' badges were presented by Mayor Allenson, although the present sword and mace are not ancient. About 1617 Bishop Lord Crewe presented one silver tankard, six silver candlesticks, a silver loving-cup and cover, and a silver whistling pot and cover. There is also a silver christening cup, with the city arms engraved on it. Whilst on the question of city arms, it would be well if our City Fathers would determine on the city colours, as by usage we claim a gold cross on blue ground, but Goss's china and others show a red cross on a black ground, and a local archæologist says that either may be correct.* In addition to the Corporation silver, there are the constables' and watchmen's staffs, and the six city state halberds. The mayor's chain of office was presented by public subscription in 1870, and the mayoress's chain presented by Lady Anne Lambton in 1901.

In 1651 the Corporation purchased their borough from the Parliamentarians for the sum of 200*l.* Up to 1678 the municipal authority seemed to have its Roundhead and Cavalier tendencies to a great extent, when, owing to various disputes, the Council would not carry into effect the powers of the charter, and the government was again by bailiff. In 1780 a new charter was granted to the city by Bishop Egerton, with extended powers. This was of a quite up-to-date type, and invested eighty-nine commissioners with powers very similar to those possessed by urban district councils, such as preventing obstructions in streets, street repairs, drainage, lighting, appointing officers, collection of rates, the levying of tolls, &c. That there was need for some such powers may be seen from the report of John Howard, the prison reformer, who, on March 20, 1774, reported as to the prison at the north gate, in Saddler Street (now removed, except the underground prison cells), that there were no sewers, and dirt and ashes had lain there many months. Then from the middle of the seventeenth century each of the householders of the old and new Elvets had the quaint privilege of allowing four swine to roam in the streets. The charter last named existed until the passing of the Reform Act, 1832.

Durham, as capital city of the ancient palatinate of the Prince Bishop, still has its Court of Chancery, and is the centre of county council government, county police, and education. Its assize is attended in full state by the Judges and High Sheriff of the county.

The city has its own police, and controls its elementary education, but the modern unsatisfactory wasteful tendency of government by bureaucracy is very burdensome on the rates, and of course, as you know, both these and the Health Department are largely governed from London.

Comparatively little is left of the city wall and gateways having any special interest, that on the river bank east of the cathedral being most complete. All the quaint houses of the eighteenth century and before have disappeared, excepting a carved timbered house in Owensgate and Sir John Duck's house at the rear of Silver Street, and several houses of secondary note in Bow Lane and South Street, Crossgate, New Elvet, and Milburngate, so that we are poor in domestic antiquities, but, as if compensating for our loss, there are still the castle and the cathedral, with their cloisters and palaces, now also shorn of much of their stateliness, but not, we are thankful to say, of their dignity.

Streets.

In the 1773 Paving Act the offices of surveyor to the several parishes or townships within the city of Durham and borough of Framwellgate, having no public road or highways, were extinguished, and it was enacted that a surveyor should be appointed by the commissioners. His duties were "the maintenance of present and future pavements, sewers, drains, or watercourses, as well in the footpaths as carriageways, and of all lamps, lamp irons and posts, and to cause, order, and direct all or any of the present and future pavements in the said streets—as well in those parts used by foot passengers as used by carriages—to be taken up and the said streets, &c., to be paved, repaired, raised, lowered, or altered, and also the sewers, drains, or watercourses to be cleansed, altered, and amended, and also such footpaths to be paved with flagstones or smooth pavement, and all the horseways, carriage-ways, with good ragstones, pebbles, &c., and also shall cause, order, and direct the several streets, lanes, ways, and public passages and places to be cleansed and lighted, and all annoyances, obstructions, nuisances, and encroachments to be removed, and proper sewers, drains, sinks, gutters, and watercourses to be made for conveying water off and from the said several streets, and the several houses and buildings within the city, borough, suburbs, and streets. And the said commissioners or any seven of them may contract with any persons for paving, raising, lowering, amending, repairing, cleansing, &c., and all and every the works done in pursuance of this Act to be inspected by their surveyor or surveyors, or such other person as they shall from time to time appoint. And their surveyor, having an order in writing from the commissioners, may search for, dig, gather, and carry away any stones (flagstones and kerbstones excepted) gravel, sand, or other materials proper for the raising and repairing of the said streets, &c., out of and from any waste ground or common, river, or brook, in any parish, township, or place in or within three miles from the said city, without making any compensation, and also flag and kerb stones, making compensation for the same. Such surveyor or other persons filling up the pits or quarries, levelling the ground, or sloping down the banks, or railing, or fencing off where such material shall have been taken from, so that the same may not be dangerous to passengers or cattle, and if any person or persons shall obstruct, hinder, or molest any surveyor or other officer, workman, or person who shall be employed in the performance of their duty under this Act, such person shall for the first offence forfeit 20*s.*, then 30*s.*, and after 3*l.* No person shall make any alteration to the pavements upon pain of forfeiting the sum of 10*l.* without the consent of the commissioners. No branches to be made into drains without leave under a penalty of 20*l.* All private drains which shall communicate with any of the public drains, sewers, or vaults shall be repaired and cleansed under the inspection and direction of the surveyor at the cost and charges of the owners or occupiers."

The streets of the city in 1816 were evidently mostly unpaved (or were covered with rough sandstone slabs bedded in earth, as had been the class of paving used for generations on the roads in which the priors and deans and chapter were interested), as they were described "as soft as an Irish bog, and not paved with stones point upwards as some other towns." Not much notice was taken of complaints such as this, but on May 2, 1820, tenders were asked "for keeping in good and sufficient repair the horse and carriage ways

* It is the function of the Heralds' College, not of the City Fathers, to determine the correct arms of the city.—Ed.

Digitized by Google

within the city of Durham and suburbs thereof," the contractors to find all material. However, matters went on much the same until in 1822 the township of Gilesgate was fined at the Easter sessions 80*l.* on account of the imperfect and dangerous state of its streets, and the parish of St. Nicholas was allowed till next sessions to put its streets in repair. Indictments were also applied to the whole of the streets in the line of the Great North Road—viz., Church Street, New Elvet, Elvet Bridge or Souter Raw, Sadler Street, Market Place, Silver Street, Millburngate and Framwellgate, and were of a wholesale description:—

1. The wretched condition of the streets, all of which are at this time in an indictable state, and two of them (as above) actually under indictment.

2. The flagging, which is rendered perfectly useless in wet weather in consequence of the houses not being spouted, and which is receiving great injury from the droppings on it.

3. The intolerable and most disgusting nuisance of the butchers' shops on slaughtering days, as offensive to common decency as it is horrible and shocking to human nature.

4. The practice of wheeling into the streets in the middle of the day every species of the most abominable filth that can possibly be collected together.

5. The defective lighting of the town.

6. The discontinuance of the watch since 1815, so that the present police is supported by voluntary subscriptions.

Surely this is an extraordinary glimpse into the state of towns in these times, and Durham is quite typical of Newcastle, Sunderland and other towns. At any rate, these rigorous measures seemed to do some good, for I find the first advertisement for flagging in June, 1822, "to be not less than 3½ inches thick," and to take no more than three to a super. yard. Again, the commissioners voted 20*l.* on February 4, 1823, to be expended in clearing the streets of snow, the work being completed by the 6th, "but the snow is still falling."

The first mention of McAdam's system here was in 1823, as being less expensive than paving, though in 1821 the following advertisement would suggest that McAdam and his system had taken hold:—"Wanted, a general surveyor, to take the superintendence of about 75 miles of road upon four turnpike trusts in the south of Durham. The salary will be not more than 300*l.* a year, and the gentleman must be perfectly acquainted with McAdam's system of making and repairing roads, or make himself so, and produce a certificate of his sufficiency from Mr. McAdam before he enters upon the office." This rather smacks of examinations.

In Durham city in September, 1823, the pavement of Hallgarth Street was taken up and macadam substituted. In February, 1824, a public meeting decided to repair the street of Old Elvet on the plan of Mr. McAdam.

In May of this year, however, we learn that "doubts have been entertained of the expediency of Mr. McAdam's new system of road-making, as far as regards towns from the great annoyance occasioned by dust. A discovery, however, has just been made by Mr. Gilmore, surveyor of the road between this city and Tynebridge. It consists of the application of a portion of the bittern, or oil of salt, which has not only the effect of completely laying the dust, but it operates also as a cement, making the pavement at once firm and smooth, while the expense will in all probability be less than by the application of water." Apparently some other streets in the city were converted into macadam roads, but in September, 1830, it was decided to pave with stone, repair and maintain the street from the Claypathgate to the toll-bar in Gilesgate. After the severe winter of 1830 it was decided by the Dean and Chapter to employ the starving labouring men out of work at 2*s.* a day improving the public walks in the vicinity of the town, and the public subscribed 191*l.* 19*s.*, while the Chapter gave 200*l.* In deciding on this 2*s.* a day the following table was considered:—

Year.	Wages per day.		
	s.	*d.*	
1350 . .	0	2	would buy 1¼ peck of corn
1450 . .	0	4	„ 1 „
1550 . .	0	8	„ 1 „
1650 . .	1	2	„ ½ „
1750 . .	1	0	„ 1 „
1800 . .	2	6	„ ⅝ „
1820 . .	1	10	„ ⅝ „
1830 . .	2	0	„ 1 „
1909 (to-day)	2	6	„ 1½ „

By this time the streets appear to have been put into order.

It will be interesting to learn that in 1831, under the Paving Acts, the following toll-bars produced per annum:—Framwellgate Gate, 310*l.*; Butterby Lane Gate, 251*l.*; Gilligate Gate, 231*l.*; Hallgarth Street Gate, 55*l.*; Stonebridge Gate, 58*l.*; and Ushau Lane Gate, 12*l.*; or a total of 917*l.* In 1844 the toll-bars produced 822*l.*, and in 1846 only 630*l.*

In 1801 the city population was				7,628
„ 1811	„	„	„	7,953
„ 1821	„	„	„	9,814
„ 1901	„	„	„	14,659
„ 1901	„	„ (including added area)		17,200

Now, assuming the same rateable value per head, viz., 4.5*l.*, in 1801 as in 1901, the rateable value would then be 34,326*l.*, or 1*d.* rate would bring in 143*l.*; so that the toll-bars would only produce an amount equal to a 6.42*d.* rate, and this to provide for all the lighting, repaving, and scavenging under the Paving Acts, exclusive of maintenance of the various parish workhouses, of which there were five. In 1808, in St. Nicholas alone, the pauper expenses were 1,500*l.* per annum, and the rates were one-third to one-half of the annual value of properties in that parish. For the year ending March 31, 1908, the total rates for the parish of St. Nicholas were 6*s.* 5*d.*, inclusive of police, education, poor, county, and other purposes.

By the year 1840 the whole of the principal streets of the city were paved with cobbles, with local sandstone flags and kerb. These were replaced by granite paving and Pateley Bridge flags up to 1860, when Caithness flags were partially used for the first time. Then, about 1870, the streets were repaved with granite, with, in places, granite wheelers, 6-inch Fifeshire black whin kerb, and generally with Caithness flags.

Since 1900 Old Elvet and the Baileys have been tar-paved, and York non-slip granite face concrete and Barnard Castle flags have been used, as well as Caithness flags and Fife kerb. There is no wood, cork, or asphalte paving, these being considered unsuitable for a district where the horse-shoes must be chisel caulked to enable loads of 12 cwt. to 16 cwt. to be hauled.

The two bridges are repairable by the county, who appropriated an ancient fund arising from lands in Gilesgate for that purpose, which in 1846 produced annually 24*l.* 15*s.*

The Council have recently put in force the Private Street Works Act.

We receive from the county council the sum of 330*l.* per year for the repair of 1.434 miles of macadam road, and such extra amounts agreed on after having had plans and estimates for larger improvements approved by the county surveyor. The remaining 18.116 miles of roads cost at the annual rate of about 85*l.* per mile for repairs and renewals, exclusive of all watering and scavenging, and provision of new paving for existing setts. It must be borne in mind that some 9.62 miles are paved, or not yet repairable by the inhabitants at large, so that this would make the fair cost about 170*l.* per mile. I have for several years tried dust-layers, Westrumite, Akonia, and Crempoid, and used the latter again for our miners' day, July 24. I have had a trial length of road surface tarring done.

After hard work, I am glad to say that in 1905 Major Norton recommended an extension of the city boundaries, which took place in November, 1906, with the following result:—

	Acres.	Houses.	Population.	Rateable Value.	Miles roads.
Old city	884	2,732	14,772	56,256*l.*	16.00
Added area	181	444	2,220	9,500	3.55
Total	1,065	3,176	16,992	65,756	19.55

General Works.

It would take too long to give details of works that have been contemplated, and in most cases carried out. Wherever possible, all specifications and quantities are printed, quarto size, with a short form of legal agreement and schedule of prices, a pattern I copied from Mr. Creer, late of York, as the best of its kind I have known. These apply alike to "supplies," such as horse-food, farriery and veterinary work, cartage, roadstone, limewashing lanes, scavenging, painting, disinfectants, flags, kerbs and channels, setts and brushes, and also to special contract works, viz., flood prevention works, tar macadam, baths, plumbing and repairs, water mains, private street works, new carts and covers, alterations to stables, electric bells, electric wiring, fever hospital repairs and relining, weights and measures office, box for sick horses, town hall alterations and windows, corrugated shed and straw store, fire brigade apparatus, baths, destructor furnace, &c., ferro-concrete bridge and weir, riverside retaining wall and river protec-

Digitized by Google

tion works, connections to Mannesman steel sewers of private house drains, alterations and repairs to gas engines, pumps and pump well, underground lavatories, cast-iron sewers and junctions on brick piers, alterations to police station, &c.

This form, used with care, has the great advantage of avoiding claims for extras, excepting, of course, the unavoidable "extensions" which occur from time to time.

(To be continued.)

OUR CONTEMPORARIES FROM OVER-SEAS

THE *American Architect* now illustrates some additional buildings in Atlanta, Georgia, and also the Peabody Library of the University of Georgia at Athens, in that State, a classical building mainly in brick with stone dressings. The examples from Atlanta do not impress us favourably. There are some interesting illustrations of designs by students under the *régime* of the Society of Beaux-Arts Architects, which show how it is endeavoured to give American architectural students the benefits of the Parisian system of instruction without coming to Europe.

Deutsche Bauzeitung continues its illustrations "architectural and otherwise" in connection with the International Archæological Congress at Cairo held in April last. Our contemporary also gives, with illustrations, an account of the new Old Catholic Church at Cologne, the design of which by Herr Peter Recht is based upon the Romanesque work of the Rhine provinces, simply and broadly treated.

Moderne Bauformen shows by several illustrations of the work of Eliel Saarinen of Helsingfors how the "new art" movement has penetrated even as far north as Finland, and quite remarkable in their power of composition and simplicity of detail are some of these designs, notably that for the Landtag's building at Helsingfors. The work of Professor Otto Prutscher, of Vienna, at the International Photographic Exhibition at Dresden gives us some very satisfactory treatments of internal architecture. Amongst the other illustrations worthy of note are those of Messrs. Esch & Anke, of Mannheim, who do not always follow "new art," but use conventional motifs with freedom and originality.

La Construction Moderne, with an appreciation by Alfredo Melani of the charms of Genoa, gives us an illustration of the Villa Paradiso near that city. As exemplifying the influence of the architecture of Genoa, Signor Melani refers to the Palais Bagatti-Valsecchi at Milan, of which also illustrations are given, and of which the proprietors are the architects, with considerable indebtedness to the old work of the fifteenth and sixteenth centuries.

The *Architectural Record*, in its review of architecture in the United States, now deals with "The Skyscraper," in which it is made evident that Americans realise the evil of these "mercenary monsters," and joins in the dirge:—"These leagues of buildings, describable and indescribable, are not beautiful, but sinister. One feels depressed by the mere sensation of the life which created them—life without sympathy; of their prodigious manifestation of power—power without pity. They are the architectural utterance of the new industrial age." Not only the evil these monstrosities do to the light and air of the city, but the imminent risk of a catastrophe from fire is emphasised. An interesting article is included on Artistic Parisian Shop-fronts, with illustrations of a dozen examples.

The *Engineering Record* has an interesting description of the shoring and underpinning of a tall church steeple, consisting of a tower 92 feet high, with a slate-covered timber spire rising to 146 feet from the street level. This is the steeple of St. Paul's Catholic Church, in Vicksburg, Miss.

COMPETITIONS.

AT the last meeting of the Keighley education committee it was recommended that the proposed mixed school for Highfield—which will include a central hall—should provide for 240 new school places, the details to be arranged by the sub-committee; and that architects residing or carrying on business in Keighley be invited to send in competitive plans, along with estimate of cost and tenders.

Nine designs were submitted for the proposed Pilgrim Fathers' Memorial at Southampton, and last week that by Mr. R. M. Lucas, Bar Gate Chambers, Southampton, was accepted. The base of the monument jutting some 16 feet from the sea wall carries a corbelled projection in the form of a prow of a ship. Its sculptured figure-head is Hope, raising her anchor and bearing a wreath, from which garlands depend. The eight panels of the pedestal are intended to be of bronze in low relief, and a group of three figures considerably above life size completes the composition. The materials are Portland stone and bronze. The cost of the constructional work, including a pile foundation, is estimated at 650*l.* This leaves for the sculpture, the carving, and bronze panels, and the lamp standards a balance of 1,350*l.*

A SPECIAL meeting of the Stoke Town Council was held on August 12 to receive the award of the assessor (Mr. Leonard Stokes) in the competition in connection with the town hall extension scheme. The following letter had been received from Mr. Stokes, dated July 30:—"A careful examination of the designs sent in for the town hall extension competition will, I think, show that the sum of 25,000*l.* is hardly adequate to meet all your requirements. However, of the less costly designs, I am of opinion that the best is No. 33, and the second and third respectively Nos. 1 and 37." The committee reported as follows:—"Your committee having carefully considered the same and made a detailed inspection of all the designs submitted for competition, cannot recommend that any one of them is of such a character as to justify the Council in carrying it out, mainly on account of the excessive price. Your committee also further report that having made a further inspection of the designs placed first, second and third, they are of opinion that as the cost of the first and third materially exceeds the sum of 25,000*l.*, they are disqualified under rule 15 of the conditions, and that other sufficient reasons exist for not adopting such designs. With respect to the design placed second by the assessor, although they are not prepared to recommend its adoption, your committee consider that as regards cost it more nearly conforms to rule 15, and that therefore the premium of 100*l.* should be awarded to its author." The committee recommended that the whole matter should be reconsidered. It was explained that the names of the authors were unknown to any member of the Council. The design placed first by the assessor was estimated to cost 29,000*l.*, and the one placed third would cost 30,853*l.* The design placed second was estimated to cost 25,015*l.* In accordance with the recommendation, the matter was referred to the Council in committee. The designs placed first and third by the assessor being disqualified, the Council have not opened the envelope containing these competitors' names. The authors of the design placed second are Messrs. Warwick & Hall, of Gray's Inn, W.C.

Correspondence

[The Editor will not be responsible for the opinions expressed by Correspondents.]

Brick Clay a Mineral.

SIR,—By his statement on Monday last that brick-clay is a mineral, and will be treated as such for the purposes of the Finance Bill, the Chancellor of the Exchequer has established a precedent that will not only involve most serious consequences for owners—and ultimately for lessees—of brick-clay property, but one that is likely to have a far-reaching effect upon owners of clay property of all kinds.

The question which I put in the House of Commons reads as follows:—

"Whether, in view of the facts that Mr. Justice Buckley, in the case of the Great Western Railway *v.* Blades, in 1901, said that within the decision in the case of Glasgow Corporation *v.* Farie, in 1888, 'the same clay may be a mineral in one district and not in another';

"And that both these cases are cited in that of the Great Western Railway *v.* Carpalla United China-clay Co., Ltd., to which the Government referred on June 21 last for the general meaning of the word 'mineral';

"And that no common brick-clay has, since 1888, been held to be a 'mineral' for the purpose of receiving compensation under the Railway Clauses Consolidation Act of 1845, the Chancellor of the Exchequer will specifically declare common brick-clay not to be a 'mineral' for the purposes of the Finance Bill?"

To this Mr. Lloyd George has replied:—

"There is no doubt that brick-clay is a mineral in the ordinary acceptation of the term, and it is not proposed in the Finance Bill to make any exception of brick-clay.

Digitized by Google

"The cases referred to do not affect the general question. They merely decide that, for the purpose of undertakings for which land is acquired under the Railway Clauses Consolidation Act or the Waterworks Clauses Consolidation Act, brick-clay forming the surface of the earth is to be treated as land to be acquired under the ordinary provisions of those Acts, and not as minerals, which are subject to special provisions."

Now this position is neither equitable nor consistent.

It is not consistent because on June 16 last, before Clause 12, taxing ungotten minerals, was dropped in favour of the present mineral rights duty, the Chancellor of the Exchequer said:—"Any minerals which have a separate value as such will be liable to duty under the Finance Bill. Clay in the Thames Valley has no separate market value at all." Yet Thames Valley clay is now to be taxed, at all events at places like Reading and Maidenhead, where it is used to manufacture bricks.

The Chancellor of the Exchequer's present position is inequitable because for over twenty years—ever since the case of Glasgow Corporation *v.* Farie—the Courts of Justice, from the House of Lords downwards, have consistently refused to allow brick-clay to be a mineral for the purpose of receiving compensation from railway companies that have acquired clay property under the compulsory powers of the Railway Clauses Consolidation Act of 1845. How, then, can Mr. Lloyd George explain the equity of treating as a mineral for the purpose of paying money under his present Bill, the identical clay which has never been allowed to be a mineral for the purpose of receiving money by way of compensation under the Act of 1845? Moreover, no Court of Law has ever pronounced common brick-clay to be a mineral anywhere; so that the opening statement of the Chancellor of the Exchequer's reply to my question, that "there is no doubt that brick-clay is a mineral in the ordinary acceptation of the term," constitutes an absolutely new departure from the legal point of view, and a bold one at that.

China-clay and fire-clay we have long known to be minerals. We now learn that common brick-clay is to be a mineral, notwithstanding legal decisions to the contrary.—Yours faithfully, H. G. Montgomery.

43 Essex Street, W.C.: August 19, 1909.

Angles in Greek Architecture.

Sir,—Does not Omar Khayyam say in one of his Rubaiyat:—

> "The moving finger writes, and having writ
> Moves on; nor all your piety and wit
> Shall lure it back to cancel half a line;
> Nor all your tears wash out a word of it"?

I perceive Mr. Aitken's moving finger is again at work, and I fear that I have neither enough piety nor wit to get even half a line cancelled; but oh! if tears would avail, how I would shed them!

What, Sir, is the meaning of this week's extraordinary presentation? Mr. Aitken shows us that a certain relational line gives 67½° in Bassæ and Theseion temples, and he carefully avoids showing us that a similar line in Selinus gives 64° and in Concord gives 66⅞° (approximately). He shows us that another relational line gives 22½° in three cases, though he avoids showing us that in the fourth example it gives 20°. His method of selecting angular direction for diameters differs strangely in different examples, the 60° being reckoned from extremity to centre, the 67½° from extremity to extremity, and the 45° spanning an additional column and spacing beyond the 67½°.

And so the miserable procession continues. As I ventured to write recently, it is nothing but juggling—and very poor sleight of hand at that.—Faithfully yours,

Percy L. Marks.

Albert Buildings, 49 Queen Victoria Street: August 16.

GENERAL.

The Newcastle Society of Antiquaries propose to transfer their library from the Castle to their Black Gate premises. The cost will be 300*l.*, and of that sum nearly one-half has been collected.

Under the Direction of the Office of Works, a general process of renovation is being carried out in the Houses of Parliament—so far as the unusually prolonged sittings of the two Houses will allow. A number of the famous paintings, including those depicting the meeting of Wellington and Blucher at Waterloo and the battle of Trafalgar, are being "restored," and the inscriptions at the foot of some of the older stone statues have been re-cut and otherwise made more legible.

A Scheme for erecting a public hall with market place under it in Broad Street, Pershore, at a cost of about 3,000*l.*, has been abandoned in favour of a smaller scheme for buildings costing about 1,000*l.*

The Portslade Urban Council have instructed the clerk to ascertain from the Local Government Board if sanction was likely to be granted for a loan of 5,000*l.* for the erection of a town hall, also the longest term likely to be granted; the surveyor to ascertain and report upon eligible sites.

A Proposal to establish a Jewish Hospital in London was approved at a mass meeting last week. A site of 20,000 square feet has been selected at Stepney Green, which will be submitted to a committee at a conference to be held shortly.

Amongst the new schools which have recently been erected at Bristol to meet the demands of the growing population in the outside districts are those in Sommerville Road, built by Messrs. Humphries & Son from the designs of Messrs. Gough & Sons, of Bristol. The whole of the stone used is St. Aldhelm Box Ground from the Box Hill quarries.

Mr. George Harwood, M.P., is presenting to Bolton a monument inscribed with the leading historical dates in the borough's history. Some fine monoliths of Dartmoor granite have been cut from quarries at Merrivale, near Princetown, and these will form part of the monument. The circular base will measure 10 feet in diameter and the shaft will be 20 feet high. On the top of the column a large bronze cross is to be fixed, and on the four sides of the square block bronze shields will be placed containing historical inscriptions, commencing with 1253 A.D., when a charter was granted. The site is that of the Old Market Cross in Churchgate, which it resembles. The memorial has been designed by Messrs. Bradshaw & Gass, architects, Bolton.

Mr. Munro Ferguson, M.P., in the House of Commons last week, asked the Lord Advocate whether the attention of the Secretary for Scotland has been called to the published annual reports of the Director of the Royal Scottish Museum and to a recent official return from which it appears that during the period of ten years ended March 31, 1908, the sum of only 1,274*l.* was expended in Scotland on the purchase of sites, erection of buildings, and extension of existing buildings, while in the same period 550,597*l.* was expended for similar purposes on the London museums, and will he say whether any steps are being taken to provide the increase of accommodation required by the Royal Scottish Museum? The Lord Advocate, in replying, said the question will be considered when the estimates for 1910-11 are being settled.

Mr. William Ford Stanley, J.P., F.G.S., F.R.A.S., &c., died on the 14th inst., in his eighty-first year at his home in South Norwood. He was for half a century head of Messrs. W. F. Stanley & Co., Ltd., a name which must be familiar to all architects, engineers, surveyors and builders. His own merits as a scientist made his position well-nigh unique in providing for the requirements of the learned professions. Many famous men have acknowledged their indebtedness to his encouragement and business acumen. On retiring from active life Mr. Stanley bestowed in 1903 on South Norwood a public hall and art gallery, at a cost of 13,000*l.*, the design being entirely his own. He added a clock tower and second hall, and afterwards erected and equipped the Stanley Technical Trade Schools, where boys receive general education and technical training combined. They have been endowed with property valued at 25,000*l.* Under a trust deed executed with the Charity Commissioners the future administration of the schools and the halls is fully provided for. Mr. Stanley was made an honorary freeman of Croydon in 1907, and in the same year a clock tower was unveiled in South Norwood to commemorate his munificence.

At the Mansion House fire prevention improvements are in progress. The work is being executed for the Corporation on plans and suggestions made by Mr. Sydney Perks, F.R.I.B.A., city surveyor. The general scheme is the separation of the Egyptian Hall from the domestic offices and State apartments by means of steel doors. Special attention is being given to the Egyptian Hall, as it is erected immediately over the kitchens. Iron and steel doors are also being erected in the State drawing-rooms and the saloon, and an iron and glass screen will be placed at the east end of the Egyptian Hall. Iron gangways are being placed on the roof to facilitate the escape of the domestic staff, and fire alarms and appliances are being overhauled and hand extinguishers provided throughout the building. The cost of these works will be over 1,000*l.*

FORTHCOMING EVENTS.

Saturday, August 28.

Architectural Association: Camera and Sketching Club, Visit to Hayes, Harmondsworth, and Harlington.

Thursday, September 9.

Paint and Varnish Society: A paper will be read entitled "The Painting of Plaster," by Mr. W. Fourniss.

Saturday, September 11.

Society of Architects: Students' Sketching Party.

Architectural Association: Camera and Sketching Club, Visit to Guildford and district.

Monday, September 13.

National Association of Master House Painters and Decorators of England and Wales: Annual Meeting at Sheffield, September 13 to 18.

BRICK-EARTH AS A MINERAL.

THE thanks of all concerned with building are due to Mr. H. GREVILLE MONTGOMERY, M.P. for Bridgwater, for having obtained from the Chancellor of the Exchequer a definite answer to a question that is of considerable importance to architects and their clients, to builders and their customers—the question whether common brick-clay is or is not a "mineral" and so liable to the taxes to be borne by "minerals" under the provisions of the Finance Bill.

In our correspondence columns last week Mr. MONTGOMERY has given verbatim the text of his question and of the reply of Mr. LLOYD GEORGE. The Chancellor has decided that brick-clay is a "mineral" for the purposes of his Finance Bill and that he does not propose to make any exception of brick-clay from the minerals that are to pay tax. He thus sets his dictum, that of a provincial Welsh solicitor, against the carefully weighed decisions of numerous judges of the High Court from the House of Lords downwards, who have ruled that brick-clay is not a "mineral" and therefore deposits of brick-clay compulsorily purchased by railway companies are not entitled to special compensation on account of their value as "minerals."

Of course Mr. LLOYD GEORGE's law varies according to the political exigencies of his position at the moment. When he is arguing in favour of a tax on ungotten minerals, the absurdity of taxing all the clay in the country was too great even for him, and he declared that clay has no separate market value as a "mineral" and therefore would not be taxed as an "ungotten mineral." Now having dropped the tax on ungotten minerals and substituted another on mineral rights, clay is exalted to the sublime rank of a "mineral" and as such expected to pay tax. Such are the shifts of an inconsistent Chancellor of the Exchequer. Never mind the law—when a country practising solicitor becomes Chancellor the rulings of all the judges in the country, impartial and unprejudiced as they are universally admitted to be, must be put on one side and his dictum becomes the law of the realm.

Mr. LLOYD GEORGE's decision to tax brick-clay seems to be as deficient in justice or equity as in law. When brick-clay is to be debarred from receiving compensation under the Railway Clauses Consolidation Act or the Waterworks Clauses Consolidation Act it is not a "mineral," but when Mr. LLOYD GEORGE wants to raise money on it, brick-clay is a "mineral."

It is quite an open question whether Mr. LLOYD GEORGE was not quite right when he declared that "clay in the Thames Valley has no separate value at all." Bricks are frequently made and sold at prices that after deducting the cost of labour and fuel in making, interest on cost of machinery and proportionate rental of land at an agricultural value and a reasonable profit on these leave nothing for the separate value of the clay as a "mineral." Therefore at these prices there is nothing in the clay that can be properly taxed as "mineral" value. Now it is notorious that in the brick industry prices of the same bricks vary largely, and if these particular bricks at bottom prices do not allow anything for the value of the clay as a "mineral" can it be fairly said that any proportion of the profit they obtain at top prices is due to the value of the "mineral"? Is it not due to other causes, to the operation of the law of supply and demand? Thus at top prices no profit on the "mineral" remains to be taxed.

There is another aspect that concerns the advisability as a matter of national interest in the taxing of the value of such a "mineral" as brick-earth. Every such tax must add, if it is collected, to the retail price of bricks made in Great Britain, and the margin between the price of native bricks and those from foreign countries is already very small and needs but the slightest enhancement to enable the foreigner to dump Dutch, Flemish, German, or French bricks on our market and to undersell the native producer. Thus the attempt on the part of a Liberal Government to mulct the individual who presumably owns some of the more valuable soil of the country is bound to benefit the foreigner at the expense of those engaged in a native industry, to say nothing of the fact that a tax on brick-earth must of necessity add to the cost of building and so still further increase the severity of periods of depression such as that from which the building industry now suffers. When there is a slump in building it will be more acute than before and when there is a boom the foreigner will get the advantage by having a market prepared for him in which he can successfully compete by reason of the taxation of the native source of wealth.

Mr. GREVILLE MONTGOMERY, as the editor of the *British Clayworker* and as the member of Parliament for a constituency (Bridgwater, Somerset) to whom the brick and tile industry is of considerable importance, was essentially the right man to tackle the Chancellor of the Exchequer for a clear pronouncement as to whether brick-clay is or is not to be taxed under the provisions of the present Finance Bill. Now the brickmakers and the brick users of the country know that it is the intention of Mr. LLOYD GEORGE that they should be especially taxed. It is not the owner of the brick-clay who will pay the tax, but those who buy his clay, whether in the form of bricks or as raw material. This will continue as long as the clay-owner can find a market. When the tax prevents him from using, letting or selling his land at a higher value than he can get for it as agricultural land, the clay will remain where it is, an "ungotten mineral," and the Chancellor of the Exchequer will have nothing to tax.

Digitized by Google

Thus it seems to us that not only is Mr. Montgomery—and from his position he knows what he is talking about—perfectly right in his contention that the tax on brick-clay is neither legal, equitable nor consistent, but there are other very weighty arguments against the taxation of brick-clay, particularly from the point of view of national interest.

NOTES AND COMMENTS.

From the fact that Sir Aston Webb's name is announced amongst those eminent artists who as members are supporting the Imperial Arts League, we presume that it is not the intention of the founders to leave architects outside their pale or to tacitly exclude them from the ranks of "artists." The objects of the League are, as stated, certainly in some respects concerned with matters architectural—"to make appeals for the national and municipal support of art," "to promote competent and just art criticism," "to promote the interests of artists at international and other exhibitions" are activities in which architecture is capable of being benefited as much as any other form of art, and notwithstanding that architects have their own organisations that to some extent, more or less, already work on these lines, there need be no cause for jealousy on the part of these existing organisations at the formation of another body which may help forward some of the work that they themselves are doing. It is very desirable that every effort should be made to familiarise the general public with the fact that architecture is an Art and therefore it is desirable that architects should become members of a League which appears to have excellent backing from the published names of those who are already amongst its members.

The ignorance of the present Chancellor of the Exchequer in respect of the actual business methods of the country is in nothing more forcibly exemplified than in the proposed taxation of apparently unearned increment in the case of building land. This is clearly expressed in a letter to the daily Press by Mr. T. F. Smith, an experienced speculative builder. In this it is pointed out that, as is well known to all who have occasion to look into the matter, the present-day speculative builder makes no profit on the houses he builds and sells to the public: nay more, he very frequently sells the house at less than its actual cost to him, making his profit on an improved ground rent, which, to the ignorant, may appear as "unearned increment," but which is really the profit on the employment of skill, labour and capital expended on the building of a house. The ordinary man buys a house manifestly cheap but forgets or does not realise that the often highly inflated ground rent of which he also accepts the responsibility is part of the price of the house and not wholly of the land on which it is built.

The collection of casts that has been recently transferred from South Kensington to the British Museum and for want of better accommodation has been housed temporarily in an iron shed, is a valuable field for study of Greek and Roman sculpture, although far from being complete or capable of ranking with some of the great collections abroad. Still, we must be thankful for the opportunity of seeing examples of the work of Praxiteles, Scopas, Paionius, Myron, and Polycleitus, besides that of later Greek schools and of the best Roman classical work.

Education is the chief industry of Edinburgh, and the position of the new art school which has now been a year in existence is therefore of some importance. The site was provided by the city authorities and the funds for the erection of the building were obtained from public monies and private contributions, particularly that from Mr. Grant, of Kincorth, so that the city of Edinburgh is in possession of probably the finest art school in the United Kingdom at a minimum of cost to the citizens. The cost of maintenance is also very largely borne by public funds as distinct from those of the city, and hence a good art education is possible at low fees without any great tax on the ratepayers. Under these conditions there is no reason why Edinburgh should not once again hold the high position as an educational centre in art that belonged to it formerly, before it was crippled by subjection to the rigid rule of South Kensington.

"Treasure Trove" has its own law, and therefore the "inquest" held at Yeovil on an interesting gold torque of the late bronze age and probably dating between 500 to 800 B.C. is worthy of note. The torque was found in a lump of clay in the course of building operations and sold to the Somerset Archæological Society for 40*l.*, and half its additional value, if any. No more appropriate holder could be imagined, as it is the only example found in Somerset, although several have been discovered in other parts of the British Isles. The jury found that "there is no evidence that it has ever been in ancient times hidden or otherwise concealed."

The object for which low side windows were constructed in mediæval churches is not one capable of indubitable explanation. They are often supposed to be "leper windows," intended to permit those who, on account of their affliction, were prohibited from entering a church to see the elevation of the Host, and so take part in the services of the Church. Sometimes, however, it is clearly impossible that a person outside the church could, through a low side window, see any part of the ritual of the Mass, although he might be able to hear the sound of the Sanctus bell and the chanting of the service. Such conditions have suggested that these low side windows were for the purpose of hearing confessions, and this view was urged at a recent meeting of the Archæological and Architectural Society of Durham and Northumberland, on the occasion of a visit to the church of Alwinton, by Mr. David Dippie Dixon of Rothbury. Mr. Dixon gave his view that in this instance, at any rate, the low side window was a confessional window of the mendicant friars, and in support of that view gave the following quotation:—"Thomas Bedyll, Clerk of the Council in the reign of Henry VIII., and one of the Commissioners at the visitation made on the suppression of religious houses and chantries, in a letter to Thomas Cromwell, says:—We think it best that the place where these friars have been wont to hear outward confessions of all comers at certain times of the year be walled up, and that use to be done for ever."

An improvement in the Housing and Town Planning Bill is the new clause of which Mr. Burns has given notice, providing that commons and open spaces shall not be appropriated for housing without the consent of Parliament, unless other suitable land, of equal area, is to be given in exchange and become common. The new clauses in Mr. Burns's name to prevent the acquisition for the purposes of the Housing Acts of "any land which is the site of an ancient monument or other object of archæological interest," are obviously such as ought to have been included from the first.

There are two sides to the question that is now causing some bitterness of feeling in the Church of England *à propos* of the use of her churches for purposes scarcely in a strict sense of the nature of religious services. There can be no question that our cathedrals were built exclusively for the purpose of regular and continuous worship. Now they have become to a large extent places of entertainment and amusement, both for those who go to see the records they form of the art and history of the past and for those who go to hear the productions of the works of great musicians. For these entertainments there has been a growing tendency to make special and definite charges. Sixpence to see the chapels, 2*s*, 6*d*. or 5*s*. for licence to sketch and photograph, and now for the Festival of the Three Choirs at Hereford Cathedral a graduated scale of prices for seats from 5*s*. to 15*s*. according to position. On the one hand it may be urged that those who have the advantages of the special form of entertainment that a cathedral affords, the study

Digitized by Google

of art, whether in the form of architecture, sculpture or music, should pay for the increased expense that such advantages entail in the provision of a staff and upkeep of the fabric. On the other hand, it is equally competent to allege that the tendency to graduated charges is clear evidence that the payments required are not regulated by the cost of the facilities granted, but by the extent of the entertainment provided, and therefore that the function of a cathedral or other church as a place of worship is superseded. This is a subject that may well form the basis of discussion at the forthcoming Church Congress.

The British Fire Prevention Committee has published its report on a number of interesting fire tests with doors, which appear to have been held simultaneously, and therefore afford valuable data for comparison. Four doors were tested, one an "armoured" door, one an iron door, and two composite doors, constructed and supplied by the Check Fire Door Company. The object of test in each case was to try if any of the doors could be classified as affording "full protection." As this means resistance to a fierce fire of four hours' duration with a temperature gradually rising to about 2,000° Fahr. it is scarcely surprising that the classification was not obtained. Such power of resistance is hardly necessary in the case of any door, but the doors of the Check Fire Door Company seem to us, from the report, to have established their superiority over the "armoured" door and the "iron door" in question.

It is abundantly clear that it was impossible for Chippendale and Sheraton to make or even supervise the production of all the furniture with which their names are associated, even of that likely to be genuine old stuff, and it is well, therefore, that clear evidence of the making of furniture worthy of these masters by unknown craftsmen should be preserved. In the fifth volume of the third series of the "Archæologia Æliana," the publication of the Newcastle Society of Antiquaries, there is an article on "The Company of Free Joiners of Newcastle," in which reference is made to a beautiful card table marked in pencil "John H. Goodnick made these tables, Anno Domini 1794, July 4, prentice to Jack Wilson," and a bow-fronted mahogany cabinet, in the manner of Sheraton, which bore the name of Richard Caranaby, and dated January 1, 1806.

COMPETITION FOR THE NATIONAL MUSEUM OF WALES.

THIS is the most important open competition promoted since that for the new County Hall for the London County Council. The cost for the completed building is to be a round quarter of a million, inclusive of carving, but exclusive of sculpture. It is thought that about one-third of the building will be erected in the first instance. The site is to be a portion of the Cathays Park of Cardiff that has been set apart for the erection of several great public buildings, and in which the City Hall and Law Courts, University College, the Welsh University Registry Office, the Glamorgan County Hall have already been located. The site for the Museum faces the City Hall, and the building will form a balancing feature in the general composition to the Law Courts. Thus, both in position and magnitude, the National Museum of Wales will be one of the most important of the public buildings of Cardiff.

The accommodation to be provided may be grouped in three sections—exhibition galleries, rooms for study, administration and work rooms. The exhibition galleries are subdivided into eight separate departments:—(1) History and antiquities, (2) geology and mineralogy, (3) Welsh natural history, (4) zoology and botany general, (5) industries, (6) art, (7) children's room, (8) aquarium. The administration and work rooms are to provide for (1) court and committee, (2) director, (3) keepers of departments with workrooms, (4) library, (5) printing department, (6) photographic department, (7) workshops, (8) macerating room, (9) sterilising room, (10) stone and plaster room, (11) lecture rooms, (12) refreshment room, (13) elevators, (14) stores, (15) service court, (16) porter's room, (17) telephone exchange, (18) lavatories, cloak-rooms, &c.

There is to be, as there should be in every important competition, a jury of assessors—Sir Aston Webb, R.A., John Jas. Burnet, A.R.S.A., and Edwin T. Hall, F.R.I.B.A.—and, "unless some adequate reason exists to the contrary," the author of the design placed first by the assessors will be appointed architect for the Museum, whilst premiums of 200*l*., 150*l*., and 100*l*. will be received by the authors of the designs placed by the assessors second, third, and fourth respectively. The appointment of the author of the design selected as the best as architect of the Museum is "subject to a bona-fide tender from a reliable contractor or contractors being obtained for carrying out the work within 10 per cent." of the author's competition estimate, subject to any modification for alterations.

The competition drawings required are plans of each floor, four external elevations, two sections, to one-sixteenth scale; a half-inch detail of a portion of the main front, with a section showing the internal treatment; a block plan to the Ordnance scale of one in five hundred; a perspective view 18 inches wide. The drawings are to be sent in on or before January 31, 1910.

ARCHITECTURE: ITS TRUE PRINCIPLES.—XVII.

By R. OWEN ALLSOP.

The Geometric Basis.

THE arguments that we have advanced apply more powerfully to mass—or design in three dimensions—than to mere elevational subdivisions; for here we see that the primordial geometric figures are of rigidly mathematical proportions. The sphere pleases. The cube, the equal-planed tetrahedron please by their sense of matter—arrangement in what we call order and symmetry. All the grandeur and dignity of architecture rests upon some combination of these and like forms. They were not designed by man, being co-eternal with nature and the natural. If architectural design had its nobility originally in complicated and elaborated form, then no building could compete in beauty of effect with the wedding-cake. Hence we conclude that the *straight line* either as a boundary or as an axis is the true margin of the most dignified architecture, and that the effect is moral, as well as physical and optical.

The main outlines of architecture—when dignified—is an affair then of geometrical form; and a plain rectangular building may be so broken up by secondary members that the basic original of the mass may be almost lost. Still it is the primal cause of the majestic and imposing of even a forest-like array of pinnacles and buttresses; for the pinnacles make out the right line at all similar points of the design. There may be no special interest about an oblong brick-built box and simple roof, but such a structure holds its own and expresses dignity where the heterogeneous broken group tells of nothing but haphazard origin—the work of the patcher who constructs by "throwing out" excrescences here and there after the manner of the mole. It is more than anything the expression of definite purpose that we are conscious of in the plain rectangular composition. Besides this each plane is given its utmost value and therefore its dignity is enhanced. The axis and the plane rectangular plan are the cause of the impressive rectangular mass. In such a simple cubical composition the fullest weight is given to the effect of light and shade—the greatest amount of dark and the greatest amount of light—all giving breadth. It may be taken as a rule that, where the common-sense plan is a plain rectangle, it is senseless to break up the composition with the idea of adding effect. On the other hand, the unnatural and forced formation of a rectangular block—that is where it is plainly resulting in inconvenience, is to be deprecated, since here is where enters the chance for æsthetic composing of, and variety in mass.

Digitized by Google

If building consists of harmoniously-disposed rectangular and curvilinear form, architecture must consist of the æsthetics of such form—their ultimate art effect. The highest expression arises from fitness for duty, but the fact does not assist very far in design: it is rather a touchstone to demonstrate success—a compass to show the broad general direction. If architecture is judged by (*a*) fitness or suitability and (*b*) expression of purpose, there yet remains (*c*) the pure æsthetic effect, as where sharp angle contrasts to the round and smooth, as may be put diagrammatically in a sketch such as fig. 39. It is here that geometrical regularity and symmetry are controlling factors. It must be remembered that form may be fit (for building) and yet not beautiful. In other matters, it is difficult to show that what

FIG. 39.

we should judge an ugly nose was not suited to its purpose. It seems generally acceded that we cannot study architectural form except *in situ*—in the building. If we photograph vertically up a lantern tower, the piers, beautiful in their correct position, may present, in the picture thus given (of an apparently horizontal position) that which is positively ugly and weird. On the other hand, it can be shown that mere fitness for duty is not the sole cause of beauty in architecture, for all kinds of girders and stanchions are evidently most fit and suited for their duty, yet by common consent are void of true architectural beauty of expression—for one reason, possibly, that for a generous margin of power and great excess of stability is substituted a mean, commercial "factor of safety."

If any variety of universally-admired architecture be examined, its elemental forms can be assigned either to that which is angular or curvilinear. The most fanciful of curved forms are not apparently essentials in architecture. Rectangularity must be considered the base of architectural form, all kinds of curves, even the cylinder, being subordinate. If we omit the not absolutely necessary carving and sculpture, the forms seen in severe architecture are cubes, parallelopipeds, cylinders, prisms and the like, and curves of one, or at the most two directions. It seems, therefore, reasonable to suggest that the study of the art of harmoniously correlating such and like forms, *per se*—that is, irrespective of their specific exemplification in old buildings—should be one of the first efforts of the student of architecture, if he aspires to something more than parrot-like reproduction of ancient handiwork. It may be that no *laws* are to be discovered—similar to the fundamental basis of musical harmony—but it is only necessary to continuously direct the attention to this aspect of architectural design to become eventually aware that there are numerous forms and combinations of forms that pain the eye, much as a false note in music pains the ear. Unfortunately, while the false note fades away, the intrinsically ugly form, in architecture, persists.

If we consider the main distinctive species of solid architectural form to be either rectangular or curvilinear, we may suggest that the one is, to the eye, sharp, spiny and aggressive, the other smooth and oleaginous. The idea suggests the contrast of oil and vinegar to the palate, or the effect to the touch of a blind man of a small cube and of a sphere, and the greater interest in the feel of an egg than a spherical body. In all architecture, excepting the most rude, is some mixture of rectangular and curvilinear form; but it has been shown by many accurate observers that the most impressive appearances pertain to rectangularity—the effect in perspective of rectangular and rectilinear figures. Obviously, however, the sharp sets off (enhances) the smooth and *vice versâ*, so that we might be tempted to say that the *flavour* of an architectural composition was referable to the amount of "oil" and "vinegar" therein—their relative proportion.

It has been suggested that the plain cylindrical column has an effect of *sleekness*. There may be a good deal in this, which, however, does not condemn this column, but suggests that the oleaginous element is here in excess or wrongly applied (as a column against a smooth, bare wall), and that the smoothness of the column should be properly contrasted to its opposite. It is certain that plain, cylindrical, attached columns require much ruggedness round about them—a principle that has been most elegantly applied in the upper storey of the bold and refined Institute of Chartered Accountants, where the wall surfaces between the plain columns are broken into a wealth of sharp angular masses.

All this can only be seen in the true natural way—that which the architect calls "perspective." If we run our eye up the angle of St. Paul's campanile, the varied play of geometrical position and form leaves an impression of harmony. The cause is beautiful planning. All fully-modelled architecture—as contradistinguished from a skin-deep, elevational scratching of a pattern—shows an appreciation of the fact that a circle is a circle and a cube a cube. A Doric column is architecture complete in three dimensions, and the pleasing effect of a mere flat plan having a circle inscribed in a square is exhibited to the eye in the solid as a contrast of a real rectangular mass to a real curvilinear one, all harmoniously subordinated to the self-same axis. Two-thirds of the beauty is based on geometrically beautiful planning, yet we find abundant serious discourses on the principles of Greek architecture with sole reference to and solely illustrated by elevational drawings.

The study of architecture as a composition of surfaces having planes at various angles and curves of various kinds awakens an interest wholly wanting where the art is regarded as based primarily on the reproduction of old forms. The sculptor exhaustively studies the human form. The correct study for the architect is geometrical solid form, its æsthetic effects, based on fitness for duty and expressiveness of purpose as something foundational. Egg-and-tongue and dog-tooth must be regarded solely as pearl necklaces. It requires to be understood that whereas a façade has but one elevation, it may have a great number of different plans—or horizontal sections—which, as the eye is directed upwards at increasing angle become dominant in the ultimate effect, reducing the position of elevational matters to one of quite secondary importance. It is difficult to see how there can be beautiful building without beautiful planning, and a certain measure of the final resultant beauty can always be seen in the mere pleasing effect of harmoniously disposed squares and circles and other superficial geometrical figures on the plan itself. Considered in this light, Architecture = Plan^2 × Elevation. All great works show masterly planning, not merely practical but artistic. To run one's eye up a façade composed of parallel lines leaves the impression of monotonous bell-tolling—a repetition of the same note.

It must result that the architect should be pleased with the effect of the mere contrasting and other harmonies of square, triangle and circle—not to the end of exhibiting these as superficial diagrams on an elevation, but that they may be displayed in conjunction with elevational proportioning, and result in perspective architecture.

(*To be continued.*)

PART I. OF THE FINANCE BILL 1909 AND THE CONSTITUTION.

By W. S. Holdsworth, D.C.L.

THE report of the General Council of the Bar upon appeals from the Commissioners under Part I. of the Finance Bill, 1909, which we print below, is of a great deal more than merely legal interest; and, though the Government has given way upon this question of appeals and restored the jurisdiction of the Courts, it still possesses a very practical interest and importance, because it raises an important question of constitutional law. That the provisions of the Bill upon this subject were unconstitutional is admitted, we take it, by the concession of the Government. But how many more proposals of a like character are contained in the closured clauses? This question is most important, for upon the answer to it obviously depends the legality of any amendment which the House of Lords may make to them. It may be that the House of Lords cannot amend, and can hardly reject an ordinary Finance Bill. It is clear that a wholly different question is raised when it is asked whether the House of Lords may or may not amend or reject proposals contained in a Finance Bill which run counter to the whole spirit of the constitution. Such proposals are not necessary parts of a Finance Bill; and to add them to such a Bill is to revive the old device of tacking—a device adopted in the late seventeenth century, and long since objected to by the House of Lords, and discarded as unprincipled—whereby the House of Lords were obliged to pass a measure to which it was thought they objected by tacking it to the Finance Bill of the year.

What do we mean, then, when we say that a proposal is unconstitutional? The term is proverbially vague in English law. We have no written constitution like that of the United States; and anything enacted by Parliament is law, for Parliament is a sovereign law-making body. The term, therefore, cannot mean simply illegal. If it did, no statute could be described as unconstitutional, since no statute can be illegal. The term is generally used to mean that there is something in a proposal opposed to the spirit and the unwritten principles of the constitution. The law of the constitution is founded on principles for the most part unwritten. These principles are assumed as a basis and a starting point by all our great constitutional statutes—by the Petition of Rights, the Habeas Corpus Acts, the Bill of Rights. Laws or proposed laws which infringe these principles are rightly described as unconstitutional. No doubt this gives a certain vagueness to the term which deprives it of some of its force. Politicians use it on slight grounds as a term of abuse. But whatever the practice of politicians, we do not think that lawyers are in the habit of using the term of any measure unless it really does infringe some vital principle of the constitution. The report which we are considering supplies us with an excellent example of an unconstitutional proposal. It is clear that the clauses of this Bill which dealt with appeals from the Commissioners in matters relating to the increment value duty, the reversion duty, the undeveloped land duty, and the mineral rights duty offended against two vital principles of English law. The first principle is that persons whose interests are affected by a taxing Act should be able to bring the question of the interpretation of the Act and of their liability under it before the ordinary law and the ordinary Courts of the land. The second is that persons who dispute their legal liability should be able to employ skilled advice to defend their interests.

The first principle was clearly infringed by this Bill. Appeals were to go not to the judges—men above all party strife, and bound by their oaths to administer the law of the land indifferently between party and party—but to the Commissioners of Inland Revenue, or to referees appointed by the Crown—men who hold office at the pleasure of the Crown, subject not only to the law of the land, but also to the orders and instructions of the Treasury. "Having regard," runs the report, "to the numerous and serious questions which will inevitably arise under Part I. of the Bill, the Council consider it of the utmost importance in the interests of the large class of persons affected, that in all cases . . . there should be an appeal from the decision of the Commissioners, and that the tribunal of appeal should not consist of a person appointed by and apparently holding office at the will and pleasure of the Crown, but that all persons whose interests are affected should be able to bring such questions before one of the recognised judicial tribunals of the country. It is obviously objectionable (if not unconstitutional) that the taxing authority or its nominees should become the sole authority to determine the amount of and principle upon which the taxes are to be levied." The second principle—that those who dispute their legal liability should be able to employ skilled legal advice—would probably also have been infringed. It was pointed out in the report that unless special rules were made the parties aggrieved would not be able to be heard by counsel. They would be obliged to appear in person. As the report says, the case for allowing professional assistance in such cases is overwhelmingly strong. "The Crown will be represented before the referee by a highly trained expert in tax law—a surveyor or inspector of taxes—whose business it will be to defend an assessment made by himself. To have upon the other side without legal assistance an appellant who, more often than not, would have no skill in advocacy, and little or no knowledge of tax law, would, in the nature of things, make a proper consideration of the case impossible."

This weighty protest has prevailed. The jurisdiction of the Courts is saved, and parties aggrieved will be able to employ experts to conduct their cases against the experts employed by the Government. But the whole episode should make us reflect upon the character of legislation which has necessitated such a protest. It is not often that the best legal opinion of the day is obliged to rise up and protest against the proposals of a Government. We cannot recall a case since the seventeenth century. And the parallel between the opposition of the legal profession to the Stuart kings and their opposition to the proposals of the present Government is indeed striking. In the earlier period the Stuart kings wished to withdraw cases from the law courts and send them for trial to the Star Chamber, a tribunal which acted on principles different from those of the ordinary law, and composed of members over whom they exercised a strict control. In the later period a Government, which calls itself democratic, wished to oust the law courts from their proper functions and to submit the liability of the property of the subject, under an Act bristling with difficulties, to a non-legal tribunal under the strict control of the Treasury and bound to obey its orders and instructions in applying the law. In the earlier period the Stuart kings feared that the law had too great a respect for the liberty of the subject. In the later period the Government seemed, not unreasonably, to have feared that the law would have too great a respect for their property. *Suum cuique tribuere*, to assign to each his due, is as much an aim of English law as it was of Roman law; and lawyers trained to apply this maxim would doubtless be bad interpreters of this Act.

We cannot doubt but that it is the right and the duty of the House of Lords to weigh carefully the clauses of this Bill in order to see that it does not contain other proposals of a similar nature. Both the House of Commons and the House of Lords are in a sense the guardians of the constitution to which they owe their being. To say that the House of Lords is bound to allow a wholly unconstitutional provision to become law because it is contained in a Finance Act would be an observance of the bare letter of the law wholly opposed to its spirit. Even in matters of private law, adherence to the bare letter of the law to the neglect of principle, and at the cost of producing injustice, is not characteristic of the best judges. In matters of public law it is at least as important that no technical rule should prevent either House of Parliament from resisting

Digitized by Google

proposals opposed to the underlying principles of the constitution. *Salus populi suprema lex*; and that the health of the people would be served by uprooting any of the fundamental principles of our constitutional law we have yet to learn.

The House of Lords, therefore, not only has the right, it is even legally bound to examine carefully the clauses of this Bill. Whether after that examination they should pass or amend or reject is a question of mixed law and politics with which we are not here concerned.

REPORT OF THE GENERAL COUNCIL OF THE BAR UPON THE QUESTION OF APPEALS FROM THE COMMISSIONERS UNDER PART I. OF THE FINANCE BILL, 1909.

1. The Council consider that it is in the first instance necessary to state the nature and extent of the questions which by Part I. of the Bill are left to the determination of the Commissioners—that is, the Commissioners of Inland Revenue (s. 74 (3)). It should be remembered that s. 1 of the Inland Revenue Regulation Act, 1890, provides that these Commissioners shall hold office during His Majesty's pleasure, and shall in the exercise of their duty be subject to the authority, direction and control of the Treasury, and shall obey all orders and instructions which have been or may be issued to them in that behalf by the Treasury.

All the taxes or duties imposed by Part I. are based on the values, or increase in values, of land (which term includes minerals) or interests in land. These values have to be determined by valuations, most of which are necessarily elaborate, and to a large extent of a novel character. It follows that the amount to be levied in respect of these taxes depends in every case on the valuations.

The effect of the Bill is to leave the determination of all these valuations (including many subsidiary matters on which the valuations depend) to the Commissioners. The powers given by the Bill to the Commissioners in regard to making valuations, and the consequent assessment of duty, may be summarised as follows:—

A. *As to Increment Value Duty.*

By ss. 1 and 2, this is a duty of 20 per cent. on the amount by which the "site value" of the land at the time when the duty is leviable exceeds the "original site value."

By ss. 1, 2 and 15, a similar duty is imposed on the amount by which the "capital value" of any minerals at the time when the duty is leviable exceeds the "original capital value" of such minerals.

The Commissioners are empowered:—

(*a*) To determine and if necessary apportion the "original site value" (ss. 16, 17 and s. 2 (3)).

(*b*) To determine the "site value" at the time when the duty is leviable (s. 2 (2) and (3) and s. 21).

(*c*) To determine the "original capital value of the minerals" (ss. 15, 16, 17 and 18).

(*d*) To determine the "capital value" of the minerals at the time the duty is leviable (s. 18).

(*e*) To decide what are minerals, and whether they exist in any particular case. This is involved in (*c*), (*d*) and (*f*).

(*f*) To decide the amount of the duty payable and the allowances to be made having regard to the amount of duty paid on previous occasions (s. 3 and s. 8 (4)); and

(*g*) To decide on what pieces of land the duty is to be assessed (s. 19).

B. *As to Reversion Duty.*

By s. 7, this is a duty of 10 per cent. on "the value of the benefit accruing to the lessor by reason of the determination of a lease."

The Commissioners are empowered:—

(*a*) To decide what is the value of this benefit (s. 9).

(*b*) To assess the duty (s. 9).

(*c*) To decide what allowance (if any) should be made on account of a previous payment of increment value duty (s. 8 (4)).

C. *As to Undeveloped Land Duty.*

By s. 10 this is an annual percentage on the "site value" as determined at periodical intervals of five years (s. 18).

The Commissioners are empowered:—

(*a*) To determine the "site value" from time to time (s. 18).

(*b*) To assess the duty (s. 13).

(*c*) To decide whether or not the land is "undeveloped land." This appears to follow from (*a*) and (*b*).

(*d*) To decide what exemptions and allowances should be made from the duty (s. 11).

(*e*) To decide on what pieces of land the duty is to be assessed (s. 19).

D. *As to Mineral Rights Duty.*

By s. 12, this is an annual percentage on the "capital value" of the minerals as determined at periodical intervals of five years (s. 18).

The Commissioners are empowered:—

(*a*) To determine the "capital value" of the minerals (ss. 15, 16, 17 and 18).

(*b*) To assess the duty (ss. 13 and 19).

(*c*) To decide what are minerals and whether they exist in any particular case. This is involved in (*a*) and (*b*).

2. There is no provision in the Bill entitling the person interested in the decision of the Commissioners to appear before such Commissioners, either in person, or by counsel, or by solicitors.

3. In the next place it is necessary to consider in what cases and to what tribunal an appeal lies.

In certain cases (mentioned later) the decision of the Commissioners is final.

In those cases in which an appeal is allowed the only appeal given by the Bill as drafted (as will be seen from the statement of the provisions of ss. 22 and 23 hereinafter contained) is to a Referee who is to be an official appointed by the Government of the day, and paid such remuneration as the Treasury direct.

The jurisdiction of the Courts is ousted for all purposes except in such cases as the Referee may think fit to state a case upon a question of law for the opinion of the Court.

Although many important questions of principle will doubtless arise in the course of determining the proper values under the Bill, it is at least doubtful whether such questions can, strictly speaking, be said to be questions of law within the meaning of s. 22 (3).

4. On the following matters the decision of the Commissioners is final, and no appeal lies:—

(*a*) The character of parks, gardens and open spaces, and of athletic grounds for purposes of exemption from undeveloped land duty (s. 11 (3)).

(*b*) The reasonableness of legal restraints by covenant upon the user of land affecting total value and site value (s. 14 (3)).

(*c*) Total or site value of land where the owner has made no return (s. 22 (1) (A)).

5. By s. 22 of the Bill it is proposed to enact:—

(*a*) That any person aggrieved may appeal against the decision of the Commissioners as to matters in which an appeal lies within such time and in such matters as may be provided by rules made for the purpose by the Treasury (s. 22 (1)).

(*b*) That the appeal is to be heard by a Special Referee whose decision is to be final (s. 22 (2)).

(*c*) That such Referee may, if he thinks fit, state a case upon any question of law (s. 22 (3)).

And by s. 23 it is proposed to enact:—

(*d*) That the King may appoint any person having experience in the valuation of land to act as Referee.

(*e*) That there shall be paid out of moneys provided by Parliament to every Referee appointed under this section such fees or remuneration as the Treasury direct.

6. There is no provision in the Bill entitling an appellant against the decision of the Commissioners to appear before the Referee, either in person, or by counsel, or by solicitors.

7. The statements contained in paragraph 1 of this report sufficiently indicate the nature of the questions which the Commissioners, or in case of appeal the Referee, will have to decide, and the Council do not consider it necessary in this report to dwell upon the great importance of such questions to landowners and mortgagees, as this has already been widely and publicly discussed in the House of Commons and elsewhere.

8. Having regard to the numerous and serious questions which will inevitably arise under Part I. of the Bill, the Council consider it of the utmost importance in the interests of the large class of persons affected that in all cases (including the cases enumerated in paragraph 4 of this report) there should be an appeal from the decision of the Commissioners, and that the tribunal of appeal should not consist of a person appointed by and apparently holding office at the will and pleasure of the Crown, but that all persons whose interests are affected should be able to bring such questions before one of the recognised judicial tribunals of the country. It is obviously objectionable (if not unconstitutional), that the taxing authority or its nominees should become the sole authority to determine the amount of and

Digitized by Google

principle upon which the taxes are to be levied. The Council consider that it is altogether wrong that the powers of appealing to the High Court and County Court afforded by s. 50 of the Succession Duty Act, 1853, imported into the Customs and Inland Revenue Act, 1885, should be excluded, as proposed by s. 6 (3) and s. 9 (4) of the Bill.

9. Should, however, the constitution of the tribunal of appeal remain as suggested, the Council consider it essential in the interests of the persons affected that every person interested should have the right to appear before the Commissioners and before the tribunal of appeal, and be heard before such tribunal and in the same manner as in a Court of Justice.

10. It will be observed (*vide* s. 22) that it is proposed that the manner and time in which appeals are to be heard are to be regulated by rules framed by the Treasury. It is unlikely that when such rules are promulgated they will be found to contain any provision for allowing professional assistance to appellants. The question of such assistance has, in the case of taxes such as the income tax and land tax, been expressly dealt with by statute. The assistance of a legal adviser is apparently allowed in the case of an appeal against an assessment to land tax. In the case of income tax (which includes for this purpose house tax) the position is different. The Taxes Management Act, 1880, enacted that "no barrister, solicitor, or attorney, or any person practising the law, shall be allowed to plead before the General Commissioners" (corresponding to the new Referee) "on appeal for the appellant or officers, either *viva voce* or by writing." The Finance Act, 1898, takes away this prohibition, making it lawful for the Commissioners to allow professional assistance to appellants, but giving appellants no right to insist on being represented. The Revenue Act, 1903, enacts that in any case where the General Commissioners refuse to permit a barrister or solicitor to plead before them, the appellant may, in lieu of proceeding with the appeal before the General Commissioners, appeal to a special income tax tribunal, which is enjoined by the Act to hear appellant by his counsel or solicitor. The tribunal would, of course, not be available in the case of appeals against assessments to the new taxes. And in the absence of express provisions on the subject by statute or statutory rules, the Referee would, it is conceived, in matters coming before him adopt the traditional rule of the Civil Service and give audience only to the appellant in person, although prepared to correspond as to any matters within his province with the agents of persons concerned. Putting aside altogether the question of professional interest, the case for insuring that an appellant shall be at liberty to have professional assistance in the Court of the Referee is overwhelmingly strong. The Crown will be represented before the Referee by a highly trained expert in tax law—a Surveyor or Inspector of Taxes—whose business it will be to defend an assessment made by himself. To have upon the other side without legal assistance an appellant who, more often than not, would have no skill in advocacy, and little or no knowledge of tax law, would, in the nature of things, make a proper consideration of the case impossible.

11. Should none of the above suggestions be accepted the Council consider that at least the Commissioners and Referee should be given power to permit a barrister or solicitor to plead before them either for the appellant or the officers of the Crown, as was provided in s. 16 of the Finance Act, 1898, repealing s. 57 (9) of the Taxes Management Act, 1880.

12. Further, as the Referee will have to consider and determine serious and difficult questions as to the principle upon which land is to be valued, the Council consider that in any case the Referee should be bound upon the request of any person interested to state a case upon any such question for the determination thereof by the High Court, or in cases where the amount concerned is small by the County Court.

For the above reasons the Council are of opinion that the Bill ought to be amended in the following respects:—

(*a*) By removing the restrictions as to the right to appeal contained in Sections 11 (3), 14 (3), and 22 (1) (*a*), and by giving an express right of appeal in the cases dealt with by such sections.

(*b*) By providing that in every case there shall be an appeal from the decisions of the Commissioners under Part I. of the Bill, and that such appeal shall be to the High Court, or in cases where the amount concerned is small to the County Court, instead of to a Referee.

(*c*) If the provision for appeal to a Referee should remain in the Bill, by inserting a provision in the Bill that every person interested should be entitled as of right to be heard before such Referee in the same manner as in a Court of Justice.

(*d*) If the last-mentioned provision should not be accepted, that power should be given both to the Commissioners and to the Referee to permit a barrister or solicitor to plead before them.

(*e*) If appeals are to be heard by a Referee, that such Referee should be bound to state a case upon any question of law or principle arising during the course of the reference, if desired to do so by any party appearing before him.

THE SETTLEMENT OF THE SAXONS.*

ARYAN, the term to denote the Indo-Germanic or Indo-European family, was first used by Professor Max Müller. The ancient district of Ariana, which became a Persian province, was captured by Alexander the Great, and the city he built is supposed to be represented by the later Herat, and in and about Ariana the cradle of the Aryan races was variously placed; but Dr. R. G. Latham in 1851, and later Theodor Benfry, advanced a theory that the races originated in Western Europe. In 1862, when Henry Christy and Edouard Lartet explored the caverns of the Dordogne in South-West France, they discovered crude engravings on the bones and tusks of extinct animals which are regarded as having been made by man when contemporary with the mammoth, and the new theory was accepted by the greatest scholars. But whether it was from Central Asia or Western Europe that the pioneers came to Britain, it is very probable that the chief hymns in the Sanskrit "Rig Veda," addressed to the god of storms and the god of light, may denote the early religion of the Celts, though the gods then had not been personified as Indra and Agni. Later, as we know, the Celts evolved or adapted a more elaborate theogony.

Natural phenomena was probably the origin of all primitive religion; the sun, the moon, the fruitful earth, lightning, thunder, hurricanes, rushing rivers and bursting springs must ever have excited reverence or awe. The oldest religion of Peru tells how Viracocha rose from the water, and having created the sun, moon and stars, he carved statues out of stone and gave them life; and Ovid tells how Deucalion and his wife Pyrrha were saved at the Deluge in a little ship and how they cast stones behind them, which gradually vivified and so the earth was repeopled. But the worship of stones and rocks seems to have originated with the falling of belemnites, or meteoric stones, and at Ephesus, Artemis was worshipped as the stone which fell from heaven. The stone was introduced into Anglo-Saxon names, like Æthelstan, noble stone; Dunstan, high stone; Ælfstan, elf stone; and Wulfstan, wolf stone. In the charters special stones and trees are mentioned as boundary marks, and the gemots or folk moots were held by sacred stones and trees.

In the Babylonian Talmud trees and stones are mentioned among the objects of false worship; but apart from "The Tree of Life" and "The Tree of Knowledge of Good and Evil" it is difficult to determine how the worship of trees originated. In the earliest collection of fables extant, the Sanskrit Hitopadesa, the Kalpa-tura, or Tree of Thought, is introduced; in the Sanskrit Mahabharata we read of a region which Arjura traversed where men and women grew on trees; in the Sanskrit Sakuntalà the trees in Canna's sacred grove have the gift of speech; and folk tales of talking trees seem common to all countries. Herodotus records that the first shrine in Greece was at Dodona. A black pigeon flew there from Thebes, in Egypt, and, settling on an oak tree, commanded that an oracle should be there erected to Zeus; charms were hung on the branches, and the murmur of the wind among the leaves was regarded as the voice of heaven answering the prayers of the supplicants. The Scandinavians and Saxons, as we know, claimed descent from the sacred ash tree, and in Britain they had their hallowed ash groves, as the Druids had their sacred groves of the oak.

The Welsh Triads are supposed to be the remains of the Druidic mnemonic system. Their pupils were instructed orally, and the Triads were handed down by word of mouth and finally committed to writing, and at the close of the eighteenth century were translated by Owen Jones. From the Triads we learn that the first man who set foot on Britain was Hu Gadarn, or Hu the Mighty; the island

* Read at a meeting of the Upper Norwood Athenæum by W. F. Harradence.

Digitized by Google

was then called Clâs Merddin, or the green spot defended by water; later it was known as Fêl Ynis, or the Island of Honey; and when Prydain ap Aedd Maur, or son of Ædd the Great, came from Armorica and obtained the government it was renamed Inis Prydain, from which, we are told, we get the Isle of Britain.

The chronicle of Nennius may date from the eighth century; in the tenth it was edited by Mark the Anchorite, and there the story of the coming of the Græco-Romano Brut, or Brutus, is given, which in the twelfth century was recounted by Geoffrey of Monmouth; but Nennius also gives another story, and records that the first man who dwelt in Europe was Alanus. One of his sons was Hisicion, whose son Brutus gave his name to Britain and peopled it with his descendants. Another son of Alanus was Neugio, whose son Saxo founded the Saxons. Some prosaic writers, however, consider that the name Britain was derived from the Brythons of Armorica, while others associate it with the Phœnician or Hebrew Baratanæ, signifying the land of tin; and though Ralph Higden, in his "Polychronicon," derives Saxon from Saxum, a stone, most writers trace the name to Saex, a knife or sword, for the Saxons were a nation of swordsmen.

Pytheas, a Greek physician, who came to Britain 300 B.C. or earlier as some writers compute, described the island as of a three-cornered shape, and Julius Cæsar, who made his memorable visit 55 B.C., also termed it triangular, so even then it may have been spoken of as the angle land. Sir Francis Palgrave and other writers conjecture that prior to the landing of Cæsar the Saxons had made incursions and had formed settlements on the south coast, but though they doubtlessly felt a superstitious terror when the blows of Thunor's hammer were heard in the storms, it is not probable that any shrines to the Teutonic gods had then been erected. With the coming of the Romans altars and temples were reared to the chief gods of the Pantheon. Whether St. Paul preached at Silchester, whether Claudia lived at Kingsbury in Middlesex, whether St. Joseph of Arimathea built a church at Glastonbury, and whether King Lucius founded the first cathedral we need not discuss, but it is quite certain there were Christian churches and bishops in Britain from very early times, and the Emperor Theodosius, who was baptized in 380, established Christianity as the religion of the State.

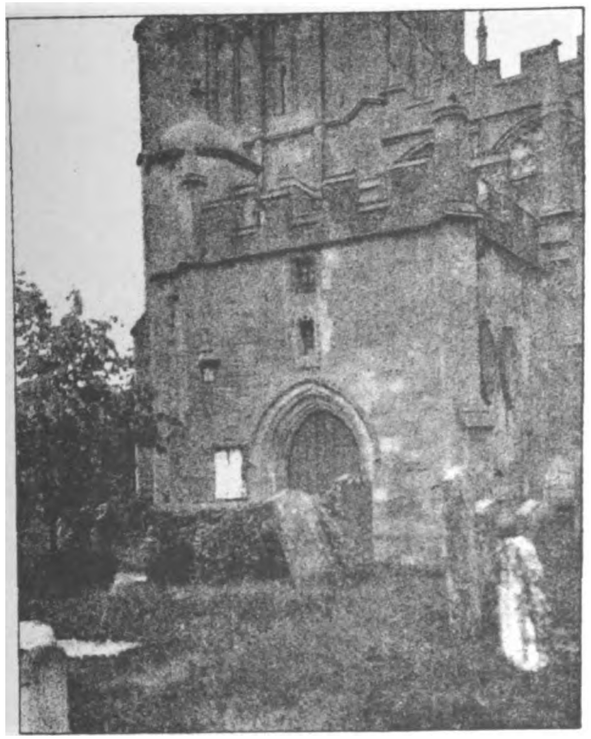
Gradually the Romans constructed their great partition walls and built their castrums, and various officers were appointed, including the Comas Littoris Saxonici par Britannias, or Count of the Saxon Shore. From Bæda we learn in the year 287 Diocletian and his colleague, Maximian Herculius, appointed Carausius, an able soldier of low birth, to guard the coasts, then infested by Franks and Saxons; Carausius, however, made himself master of Britain, assumed the title of emperor, and held his position for seven years until he was assassinated by his associate Allectus. In 364 the Picts, Scots and Attacotti united their forces, and they were joined by some Saxon pirates, who attacked the south coast, and Nectaridus, Count of the Saxon Shore, was slain. In the Notitia Utriusque Imperii, a MS. assigned to the time of Theodosius, who was made emperor in 379, it is stated that the stations under the command of the Count of the Saxon Shore were Othonæ (Bradwell, or, as some think, Felixstowe), Portus Dubris (Dover), Portus Lemanus (Lymne), Branodunum (Brancaster), Garianonum (Burgh Castle), Regulbium (Reculver), Rutupiæ (Richborough), Anderida (Pevensey), and Portus Adurni (Aldrington).

With the withdrawal of the Roman forces in 412 the raids of the Picts and Scots and the incursions of the Saxons became more frequent, and eventually, Fabius Ethelwerd says:—"Vurthern (Vortigern), then king over all, sent messengers with gifts to Germany, asking for assistance and promising help in return." But according to Geoffrey of Monmouth, who gives the most romantic account, the brothers Hengist and Horsa came uninvited. Vortigern was at Dorobernia (Canterbury) in 449, and being informed that some tall strangers had arrived in three brigantines, he ordered that they were to be received peacefully and brought to him; and Hengist stated they were seeking their fortunes, and by the good guidance of Woden they had reached his land and were willing to serve him; and Hengist told of the gods to whom they had dedicated the days of the week.

Wodensesdæg is from Woden the all-father; he delighted in battle, and only admitted to Wælheal those who died sword in hand. John Mitchell Kemble traces his name in Wanborough and Wonersh, Surrey; Wanborough, Wiltshire; Woodnesborough, Kent; Wonston and Wanborough, Hampshire; Wambrook, Dorsetshire; Wampool, Cumberland; Wansford, Northamptonshire; Wansford, Yorkshire; Wanstead, Essex; Wanstrow, Somerset; and Wembury, Devonshire. Frigedæg is from Friga, the earth goddess and wife of Woden; and her name survives in Frathorpe and Fridaythorpe, Yorkshire; Freasley, Warwickshire; and the Friday Streets in Surrey and Suffolk. Thunersdæg is from Thunor, the most valiant of Woden's sons; he was the defender and avenger of the gods, and is associated with Thundersfield and Thursley, Surrey; Thundersley and Thurlow, Essex; Thurley, Bedfordshire; Thursley, Cumberland; Thursfield, Staffordshire; Thursford, Norfolk; and Thundersley, Hampshire. Tiwesdæg is from Tiw, the protector of champions and brave men, and his name was given to Tuesley, Surrey, and Tewing, Hertfordshire; and Isaac Taylor adds Great Tew and Tew-dunce, Oxfordshire, and Dewerstone, Devonshire. Sæterdæg is from Sætare, the god of agriculture; Satterleigh, Devonshire, and Satterthwaite, Lancashire, preserve his name. Sunnandæg is from Sunne, the sun, only represented by Sonning, in Berkshire; and Monandæg is from Mona, the moon. Several other place-names derived from the gods are regarded as representing the later settlements of the Danes.

Vortigern engaged the strong strangers, who soon showed their prowess by defeating the Picts who had issued from Albania. Hengist sent for other warriors, and with them came his beautiful daughter Rowena. Having been allowed to erect Tong Castle, in Kent, or, as some say, Thong Castle, Lincoln, he invited Vortigern to a feast, and Rowena offered him a golden cup of wine, saying "Wacht heil" (be whole or healthy), and the King, being instructed, replied, "Drinc heil" (drink health), and so the fashion of drinking healths was established in Britain, and her words survived in the wassail bowl. Vortigern at once made the maiden his wife, possibly according to the Saxon usage, which consisted in the bridegroom touching the lady's neck with a shoe, a variation of the custom of placing the foot on the neck of a conquered foe, and faintly echoed in throwing a satin slipper after the bridal coach. In exchange for the lady the province of Kent was given to Hengist, and his sons received the northern part of Britain. Fresh arrivals of the Saxons continually took place, to the fear of the Britons, who, with Vortimer, the son of the king, as their leader, waged war on the Saxons, and in the A. S. Chronicle under date 455 we read:—"This year Hengist and Horsa fought against King Vortigern at the place which is called Ægels-thræp (Aylesford), and his brother Horsa was there slain, and Hengist obtained the kingdom and Æsc his son." The name of Hengist is supposed to survive in Hengston Hill, Cornwall; Hengistbury Head, Hampshire; Hinksey, Oxfordshire; and Henstridge, Somersetshire; and William Camden states that the mound bearing his name, by Conisborough Castle, Yorkshire, is his tomb. Horsa is associated with Horsham and Horsted, Sussex, and Horsted, Kent, where his grave mound is shown; and Taylor connects Horstead, Horsham and Horsey, Norfolk, and Horsell in Sussex with some one of the name of Horsa.

(To be concluded.)



ILLUSTRATIONS.

ARCHITECTURAL ASSOCIATION EXCURSION 1909.

THE whole of our plates this week are in illustration of places visited by the Architectural Association on the annual excursion this year, of which an account has been given in our last two issues. These plates were prepared from photographs taken by Mr. A. W. HENNINGS, and show the characteristic and typical architecture of the Cotswold district.

The Excavations at the Roman Amphitheatre at Dorchester will be renewed on August 30, under the direction of Mr. H. St. George Gray. Last year much attention was given to the eastern side of the entrance into the arena, when a series of puzzling post-holes, small pits, and trenches were revealed in the solid chalk. In the hope of solving their purpose by finding others, excavations will now be carried out on the western side of the entrance up to the solid chalk wall of the arena.

HOUSE AT NORTHWOOD, MIDDLESEX, FOR J. R. WUIDART, ESQ.—Forbes & Tate, Architects.

HOUSE AT NORTHWOOD.

THIS house is built in red brick and roofed with special thick hand-made sand-faced tiles. The interior is finished throughout with American elm. The accommodation consists of four public rooms, eight bedrooms, two bathrooms, and ample cloakroom, linen cupboard, and wardrobe rooms. The builder is Mr. W. King, Watford; Messrs. Forbes & Tate the architects.

THE ARCHITECTURE OF FLEET STREET.

By Lewes M'Jabols.

WE were seated in my chambers in King's Bench Walk, holding pleasant and profitable converse, and it chanced that I made mention of the rare delights of London. "Sir," said my venerable companion, James Noonlush, "London is the hub of the world, and Fleet Street is the hub of London; let us perambulate Fleet Street."

A walk with Dr. Noonlush was always, in my estimation, exhilarating, and in the present instance I anticipated a continuance of the pleasure and profit which I had just been experiencing should my venerable friend and his humble disciple take a tour among the realms of the Fourth Estate. I ventured, half apologetically, to submit this *tour-de-phrase* to the worthy Doctor's criticism, and I was sensibly relieved when he was benignantly pleased to stamp it with the hall-mark of his approbation.

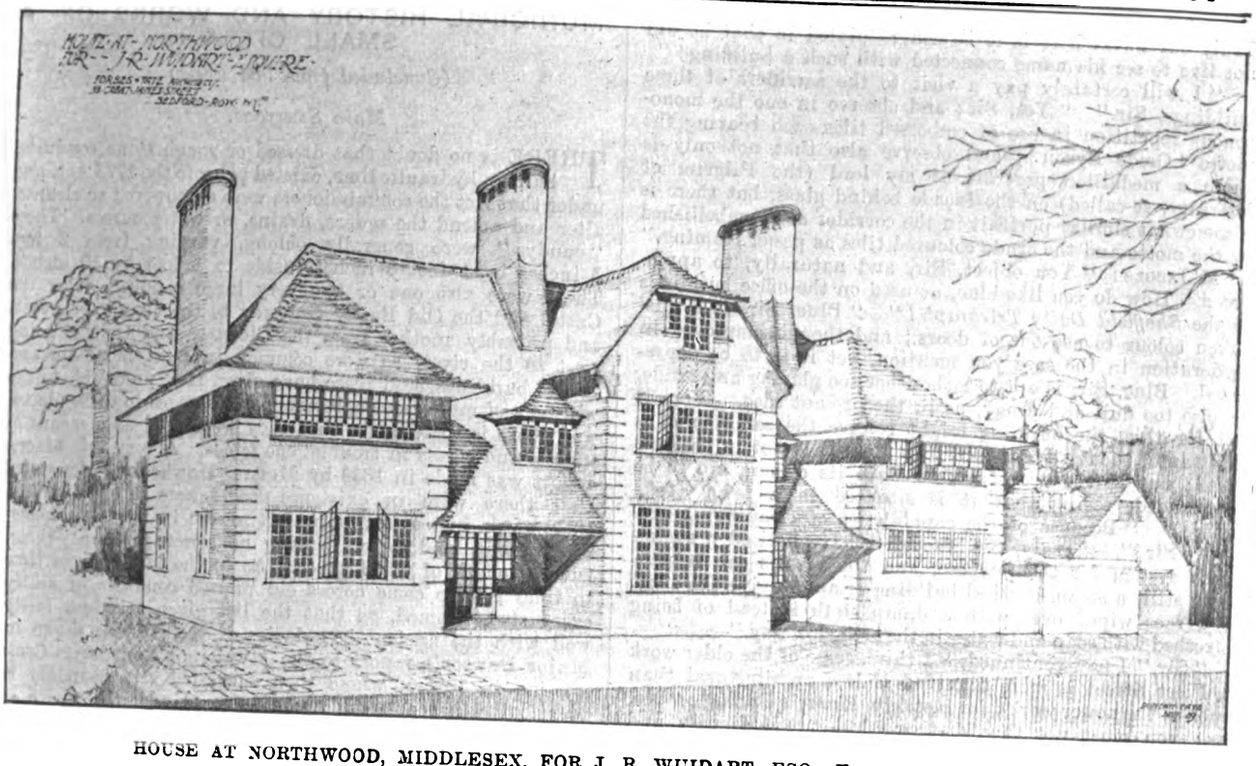
We wended our way into New Bridge Street, and were at once assailed by the roar of the ceaseless traffic. I had to strain every nerve (or, in my desire for extreme accuracy, let me say "every aural nerve") to catch the gems of thought so forcibly expressed by my friend; even now that is very imperfect, very weak—how unlike to my friend's expressions, which are always of the strongest and most vigorous type.

I was immediately seized with a desire to ask my companion what were his views on the modern development of architecture. "Sir," said he, "there is not much evidence of development, for this word implies a rational modification of the art as practised at any time to suit the conditions and tastes of the time just consequent. Now, Sir, I defy anyone to prove any such logical sequence in the work of our architects."

M'Jabols: "But, Sir, can you not conceive entirely new conditions arising at some particular period for which no precedent architecture would prove satisfactory?"

Dr. Noonlush (*with a triumphant smile*): "In that case, Sir, it would not be a matter of development."

I was struck by the brilliancy of the retort, and said no more on the point. By this time we had reached Ludgate Circus, and straightway turned down Fleet Street.



"Observe, Macky," said Dr. Noonlush, "that new building opposite us, where those respectable globe-perambulator agents are providing an extension of their offices. You talk of development. Well, Sir, I have nought to say against the frontage in its entirety; but observe that pernicious conjunction of curly gable seated on a broken pediment. Architects may say that there is not any law against such conjunction; but yet, Sir, it is surely a retrogression, not a development."

I was somewhat surprised at my worthy friend's choler, but I durst not show it. "Perhaps, Sir, it is an instance of 'Reculer, pour mieux sauter'; but, in any case, I cannot but think that the building has merits; there is some pleasing sculpture introduced, and appropriate too."

The Doctor burst out a-laughing. "You mean, Sir, that the globe is a fitting symbol to be introduced over the entrance—and you are right; but I think, Macky, that there is a further appropriateness which you have not noticed." "Pray, Sir, what is it?" "Why, Sir, do you not see the little cherubim (I would prefer to designate them 'amorini') on either side the sphere; one industriously pointing out the spots of interest and apparently gazing forward for his master's approval, the other urchin evincing no manner of interest? They are symbolical—ha! ha! ha!—of the Industrious and Idle Apprentices." I laughed in concert, but I cannot always follow the doctor's plunges into humour, though at such times I conceal this defect, as he is apt to make scoffing references to the land of my birth.

But I had put an idea into his head, and he was apparently bent on further reference to it. "You asked me as to development? Why, truly, Sir, if by that is meant the piecing together of different 'styles,' I would admit the development; for of recent years there have arisen various buildings where the elegance of Renaissance art has been conjoined to the exuberance of Gothic—and at times not unhappily. Here in Fleet Street, amongst buildings erected within the last five years or so, you may perceive

HOUSE AT NORTHWOOD, MIDDLESEX, FOR J. R. WUIDART, ESQ.—Forbes & Tate, Architects.

more than one instance of this, and on my own dear St. Clement Danes Church there is a slight admixture. But, Sir, it is not blameworthy if it be effected with judgment and taste. What I dislike to observe is the limited grasp of mediæval ideas as displayed by so many of our architects."

"Sir, I should be glad if you would enlighten me."

Dr. Noonlush: "Sir, I will with pleasure. The mediæval workers had a reason for all, or at least for most of what they did; a pier, a buttress, a gargoyle, a niche—no matter what—was introduced as reason or necessity dictated; and when they gave vent to their ideas of artistic effect, they did so on rational lines, with due regard to the sensibilities of the intelligent observer. Now consider, Sir, just one detail of those I have mentioned—say, the niche. In the olden days there was never a niche introduced without the intention of providing it with a tenant. But our architects choose to regard it merely as an ornament, and, if they want justification, point to the many empty niches on mediæval buildings. They fail, Sir, to grasp the fact that there the omission was an accident; and they fail also to perceive the lack of artistic finish provided by an empty niche on an otherwise beautiful building. And so, Sir, is it often with other features. Buttresses are now used very frequently merely as projective ornament, and similarly with gargoyles, pinnacles and other details."

We were now within sight of the offices of the *Standard*, and I was struck by the dignified appearance it presents. "Yes, Sir," said my companion, "you do well to approve it, being eminently suited to its purpose. Observe how sturdy solidity is made the first consideration, and this is modified by the free use of curved lines both in plan and elevation. Some might think there is an excess of curvature, but the criticism is uncalled for. Then, too, observe the restricted use of carved ornament. Sir, it is an entirely satisfactory building, and not the least happy feature is that fine mosaic frieze bearing the name of the journal."

Being so well accustomed to the Doctor's trenchant and caustic criticism, I could not fail to admire this noble display of fairness and good-nature on his part. His face was suffused with the glow of generous enthusiasm, but not for long, as I was very soon to see him in his customary humour, for I noticed his head rolling ominously just as we arrived opposite Mary Queen of Scots' House. Wishing to gain, if possible, some credit for discrimination with my awesome companion, I hastened to remark, "Do you think that Gothic building is very happy, Sir?" "Sir, I do not profess to enter into the feelings of the building. Let it suffice that I am not happy when I look at it; it is indeed Gothic—it is barbaric; the design is as flighty as the Queen from whom it takes its name and whose statue I see in that niche."

"At any rate, dear Sir, the first Scottish building we have encountered is not subject to your well-merited taunt about empty niches."

"Ah, Macky, you dog, but the Scottish building had to be in England; indeed, Sir, I believe the building to be Scottish only in name." (Is there anything that this learned man does not know?) He continued:—"In the entrance corridors of this house, Sir, and of some others in Fleet Street—I refer to those named after my Lords Byron and Nelson and also to Hood House—Sir Tollemache Sinclair has had marble tablets fixed—a perfect plethora in Byron House—containing significant mementoes of these various worthies. The respected Baronet is indeed no great poet, though he would fain make us think so by inscribing on the tablets favourable opinions as to his lucubrations."

M'Jabols: "Indeed, Sir, I have been rather pleased with the Baronet's muse."

"Sir, I do not say that he cannot write, and write well; but he has been unfortunate in his selections for public display; moreover, Sir, it seems too grossly a personal puff to be pleasing. And as regards foreign versification of vernacular poems, it is not mere translations are desired; the subject should be thought out in the foreign tongue, as though the latter were the original medium for the poem. His French rendering of the 'Song of the Shirt' ('Le chant de la chemise,' as he calls it) is but a translation; and it is the same in the case of his English rendering of Béranger's poem on the Queen of Scots. M. Paul Bourget's commendation of Sir Tollemache's 'Chant de la Chemise' conveys to my mind the impression that that astute Frenchman held the same views as I do. Again, Sir, I think these tablets are inappropriate in premises in such a busy centre as the City of London. Moreover, the worthy Baronet's taste in the contrast (inscribed on one tablet) instituted between my Lords Tennyson and Byron by giving statistics as to their works is not conspicuous for its merit."

"Are there, Sir, any original poems of the Baronet's displayed on the tablets?" "Sir, there are; and I refrain from commenting upon them until you have read them; but I would have you specially to note Sir Tollemache's use of the same epigram sentiments towards my Lords Byron and Nelson."

M'Jabols: "I do not much like the frontage of either Byron or Nelson Houses, Dr. Noonlush." "No, Sir; yet were it not for the crude coloured tiles spotted over the former there would not be such an aversion created, though it is in any case of too fussy a design. But Nelson House is the travesty of art. What! apple-green glazed bricks as a pattern, and such an atrocious toned background too!

Digitized by Google

Truly our naval hero is to be congratulated in that he did not live to see his name connected with such a building!"

"I will certainly pay a visit to the corridors of these buildings, Sir." "Yes, Sir; and observe in one the monotonous repetition in use of embossed tiles each bearing the motto 'Crede Byron'; and observe also that not only is there a medallion portrait of my lord (the Pilgrim of Eternity, so-called) on the façade behind glass, but there is a somewhat similar portrait in the corridor also, embellished by the motto and the crude coloured tiles as panel framing."

M'Jabols: "You object, Sir, and naturally, to apple-green. How do you like blue, as used on the office buildings of the *Sheffield Daily Telegraph*?" "Blue, Sir, is a mistaken colour to use out of doors; and though employed in moderation in the case you mention, yet it is to be deprecated. Blue, Sir, is apt to look either too glaring and crude, or else too dull and dingy, as in the present case. Were it not for this, the building might receive the sanction of a dilettante, though I am fain to confess it is not in the best taste; but in the use of glazed ware its owners are to be commended, seeing that it is situated in a town atmosphere." "Because of the capabilities of cleaning, I presume, Sir?" "Truly, Sir, though I have noticed a steam-brush system for the purpose, and the results are stupendous, still, a steam-brushed building is apt to give the effect of a face wiped over with a damp cloth instead of being refreshed with soap and water in the orthodox way."

"Sir," I now continued, "I think some of the older work in Fleet Street is more dignified if less architectural than much of the newer work; for instance, Hoare's Bank." "No, Sir; you must not thus distinguish between dignity and architectural qualities; by the latter you evidently connote prettiness, and this limits the idea much too strictly. Messrs. Hoare's Bank, I grant, is pleasing by reason of its dignified simplicity, though truly it is no magnificent piece of architecture. But look at Sir Arthur Blomfield's branch Bank of England by the Law Courts; there we have both dignity and architecture; and indeed the same may be said of Messrs. Barclay's Bank (do you remember, Sir, the old Charley's box that stood there when the old premises of Gosling's Bank confronted us?). Of course, architectural qualities may be apparent in a building that has no special claim to dignity, as in the case of the old Council House of the Duchy of Cornwall, erected in the reign of his late gracious Majesty King James I., of glorious memory; here you will see architecture both within and without." "I visited it recently, Dr. Noonlush, and received much valuable information from the custodienne; at least, it seemed to be valuable." "Why, no Sir! I dispute the value. You may as a rule rely upon dates, names and bald facts, but otherwise ciceronian information is to be discounted. The council-room, as you must have noticed, is a very interesting piece of work, and the simplicity of the oak-panelled wainscoting is pleasantly relieved by the moulded plaster ceiling."

We had been strolling back a few paces, and were now opposite the Church of St. Dunstan's, and I remarked "Does it not grieve you, Sir, to see lay buildings encroaching on the grounds of a church?" The doctor's face grew purple in its wrath as he replied: "Sir, it is a desecration; even from the standpoint of art, the lop-sided effect would be deplorable, and her gracious Majesty Queen Elizabeth's effigy is, by contrast with the former isolated position of the tower, sent much further into the background. But I am not concerned with that consideration. From the standpoint of ecclesiastical dignity and fitness, I deem it most unseemly, for the sake of filthy lucre, to deal thus with Church lands. But there, Sir, I will say no more; I would eat; let us to the Mitre, and I will toss you double or quits for payment. Ah! 'Heads'—*you* pay."

I would not dispute it with the venerable doctor, though certainly I thought it had been "tails"; however, *I* paid.

The Dean and Chapter of Durham are at present carrying out some improvements at the cathedral, the work being done under the supervision of Mr. A. Brown, the clerk of works. The most important is the installation of an up-to-date hot-water heating system throughout the entire building by Messrs. Richardson & Co., Darlington, to replace the old coke stoves. Messrs. Laidler Bros., of New Elvet, Durham, are installing the electric light in the bell tower, which heretofore was illuminated by candles. Messrs. Petty, of Boroughbridge, are re-covering the roofs of the south transept aisle and the south chancel aisle with lead.

MUNICIPAL HISTORY AND WORKS OF A SMALL CITY.*

(Concluded from last week.)

Main Sewerage.

THERE is no doubt that dressed or rough stone conduits, built in hydraulic lime, existed prior to the 1773 Act, and under that Act the commissioners were empowered to cleanse, alter and amend the sewers, drains, or watercourses. These "cundys" were generally oblong, varying from 2 feet 3 inches by 1 foot 8 inches inside to 1 foot by 10 inches. There were also one or two very large conduits from the Castle and the Old Bailey Gateway to the river going east, and probably another from the Cloisters and College going west to the river, as were common in most monastic and feudal buildings, and these have given rise, no doubt, to the whispers of mysterious subterranean passages to these places, and there is little doubt that they were used as a means of ingress and egress in troublesome times. A very voluminous report was made in 1849 by Messrs. Hawkesley, who stated that there were in existence good sewers in eight streets, 1,232 yards in length; imperfect sewers in thirteen streets, 2,181 yards, and streets having no sewerage twenty-three, with a length of 6,889 yards. As to the latter, from time to time I have come across old unused conduits in nearly every street named, so that the list given coincides fairly well with the ancient boundaries of the city, as shown in Major Dawson's report to the Municipal Boundaries Commission in 1835-6, whose then suggested city boundary is identically that existing up to 1906. Under the advice of Mr. Thomas Hawkesley, the Corporation decided to resewer the city, and a contract was let in February, 1852, for 15-inch, 12-inch, 10-inch, 9-inch, and 6-inch pipe sewers, and 3 feet by 2 feet 6 inches and 2 feet 3 inches by 1 foot 9 inches brick sewers. Had this work been carried out thoroughly, and the old sewers used to carry off the rain water, the system would have been nearly perfect, but probably in the interests of economy his scheme was only carried out so far as to replace the imperfect sewers and to sewer the streets having no sewers, a total of 9,070 yards. These sewers entered the river at seventeen different points, and generally for some distance from the outlet were under water. Very few additional sewers have been laid until the present sewerage scheme.

About 1892-3 the Corporation advertised for sewerage schemes, and had a number of engineers' plans and reports before them, and in April, 1894, instructed Mr. Fowler, of Manchester, to prepare a scheme and submit it unofficially to the Local Government Board. This he did, and produced a scheme differing little from that now nearly completed. He estimated the cost at 30,000*l.*, and the annual charges at 1,984*l.* for a dry-weather flow of 220,000 gallons during the active eight hours of the day. This scheme was too costly, and another cheaper one was eventually produced by Messrs. Lomax & Lomax, and the works commenced in 1899. They in turn were superseded by Mr. H. W. Taylor, of Messrs. Taylor, Wallin & Taylor, Newcastle-on-Tyne, who has overcome great difficulties, not without the abandonment of some of the new works executed under his scheme, and of which he will lay before you what I trust will be an instructive description.

When in 1902 I reported on the question of ventilation of the old and new sewers, I drew attention to the fact that, although the river Wear from Durham to the sea at Sunderland falls 10 feet to the mile, where it passes through the city it is ponded by means of dams or weirs (locally "stakes"), so that for weeks together there is little or no flow of water, and this of course in sultry weather. It will at once be seen why the county council urged so strongly its powers under the Rivers Pollution Prevention Act, although even with a "fresh" of 1 foot over the stakes the river becomes a torrent, and the rapid current washes down enormous quantities of gravel and sand, causing such a dilution and scour that in a short time no trace of sewage could be seen.

The old Hawkesley sewers contoured the streets at a fairly regular depth. There were no manholes, and from time to time I have built these, in laying new sewers or clearing the old ones, and wherever possible have converted the older sewers into surface-water drains only. Owing to this I should think that 15 gallons per head, with half the total flow in six hours, and allowing for twice the dry-weather flow, is a fair

* A paper read at the annual general meeting of the Institution of Municipal Engineers, held at Durham on August 7, by John T. Pegge, President.

Digitized by Google

estimate of the maximum quantity of sewage to be dealt with at the works, and Mr. Taylor will no doubt show that he has allowed for any possible increase in population in the future.

Scavenging.

The cleansing of the streets up to and for a considerable time after the 1773 Act must have been indescribable. The work appears to have been done somehow by the four constables of the city and the parish officers. We find time after time wholesale complaints of heaps of street sweepings left lying for several days, only to be, when darkness came on, traps for the unwary to walk into. The first Durham contract was advertised in January, 1819, for sweeping and cleansing the streets, lanes, ways, public passages, and places within the said city, and the suburbs thereof and the streets thereto adjoining for one year, and the streets would be let in districts to suit the parish officers. The provisions of the 1773 Act were:—"All persons shall, as soon as the foot pavement (in front or adjoining to his, her or their house) is made and completed, sweep and cleanse three times at least in every week on different days the footpath extending at least 4 feet in front. The person or persons contracted with for cleansing the said streets, lanes, ways and public passages, and all other public places, shall cause to be swept, cleansed and carried away all the dirt, dung and soil twice in every week upon pain of forfeiting 10*s.* for every neglect, and no person shall take or carry away any ashes, dust, dirt, mire, dung or manure which shall be made in any of the said streets, &c. (excepting the person or persons appointed), upon pain of forfeiting the sum of 20*s.*, provided always that if the inhabitants shall think fit to preserve and keep such ashes, manure, &c., within their own respective houses, gardens and yards, they are at liberty to keep and dispose of the same, providing that they shall not thereby offend or annoy their neighbours, and if they shall continue to keep and preserve the same for two days after notice in writing given by the commissioners or their surveyor, they shall forfeit the sum of 10*s.* a day." This penalty did not apply to rubbish, &c., occasioned by building; but all buildings in progress had to be railed in and lighted to prevent any mischief to passengers. I need not enter further into detail beyond stating that although it was decided to obtain a machine for sweeping the streets in 1846, at the same meeting the sweeping of the districts was again put up to auction. St. Nicholas and Gilesgate parishes were to be scavenged for the year for 19*l.*, South Street and Framwellgate, including Crossgate, for 6*l.*, New and Old Elvets, 6*l.*, and the Baileys 3*l.*, or a total of 34*l.* It is related in that year that Crossgate was swept on Thursday, April 23, and again on May 14 in the same year. At the present day this work (inclusive of cartage, approximately 82*l.*) costs 468*l.* per annum.

The average cost of scavenging and watering streets, cleansing of ashpits, and collection of refuse from houses and cartage to tips at suitable places since 1898 is 1,567*l.* per year, and for 1908 1,864*l.* The refuse is carted, where possible, on to farms or tipped into disused quarries. There are eight carts constantly employed, and 250 loads removed per week. I reported to my committee that almost half of this, or 120 loads, is material having a calorific value one-sixth to one-eighth that of coal, and suggested and prepared plans for a Meldrum's 1-unit plant at the baths and washhouses for the Elvets refuse; a further 1-unit plant to be hereafter built for Gilesgate and the Market Place, and a 2-unit plant at the sewerage works for North Road district and added area to be utilised in pumping the town's sewage. The baths afforded an excellent opportunity, as the coal bill is about 120*l.*, and the cartage saved would be at least 15*l.*, or (making allowance for extra labour) a saving of about 80*l.* per annum. The outcry in that district, however, was so unanimous and so well organised that the Council then decided not to proceed with the scheme.

Horses.

I might here state that we keep our own horses, and have a large corrugated-iron cart-shed and hay store over the yard, with stabling for twelve horses, boiler-house, stores, &c., and horsekeeper's house adjoining. In the lower yard there is a well-ventilated "sick" box, having a beam and tackle for slinging, with store for medicine and attendant adjoining. The cost of this was only 190*l.*, and it is invaluable. The fodder is let by contract each half-year, and the best-quality clover hay and Scotch potato oats, with a little linseed and bran, is the only food given, at a cost per horse per week of 15*s.*, including veterinary attendance and shoeing. The rolling-stock comprises rolley, two iron tumbrils, three water-carts, two horse brushes and twelve carts, mostly made locally to specification. The ashes carts have wood covers, with canvas rolls (Newcastle pattern), at an extra cost of 5*l.* 10*s.* each.

Police.

The state of towns up to the introduction of gas lighting and policing must have been indescribable. For instance, in February, 1736, it is recorded of London that street robberies, burglaries, and murders were frequent owing to insufficiency of convex lights, being defective for half a year, and for many nights during the other half, and no lights after midnight.

In Durham, prior to April, 1814, there were only two constables appointed annually for the city and two for the borough of Framwellgate. The churchwardens of all the parishes exercised some sorts of powers of policing. The roughs of that date were so much out of hand here (as in other places) that the Secretary of State interfered, and as a result the Baileys, Market Place, South Street, and the Elvets were lighted with oil lamps, but it was not until 1821 that the commissioners under the Paving Acts of 1773 appointed a member of the Newcastle Police, with others under him, "to apprehend all who transgress laws which the want of police has so long encouraged." The powers given under that Act were to appoint a sufficient number of able-bodied men, not exceeding twenty-four in the whole, to watch the said city and to be invested with the same authorities as constables have by law.

He was afterwards appointed to report all nuisances, also to inspect, along with the four constables, all weights and measures and bread, the punishment for shortage being the destruction of the weights and measures, the distribution of the bread to the poor of the several parishes, and, in addition, "mitigated" fines on the offending tradesmen.

The assize of bread was discontinued in 1822. The parish pounds for straying cattle appeared to be wholly under the control of the lords of the manors. Until the introduction of gas-lighting the police seem to have had a lively time of it. They had to cause the owners of all houses to fix spouts, so as to enable the public to use the paved footways in wet weather, to deal with loiterers at the "pullen" corner and other streets, to hale up the parish scavengers for neglecting to remove the rubbish on Saturdays, to punish offenders for breaking lamps, for slaughtering in streets, hooping or cleansing casks, sawing wood, binding, making, or repairing wheels, shoeing or farrying horses in the streets, conveying water from house roofs other than by small drains under footways, the erecting of sign-posts, sign-irons, pent-houses, bow windows, porches, sheds, butchers' gallows and crooks, cellar windows, and the erection of projections, encroachments, or other annoyance whatever, to prevent carts standing in streets, barrels being rolled on footpaths, the driving of carts, drays, wagons, trucks, or other carriages faster than a foot-pace, or without some person on foot leading the shaft or thill horse by a halter.

They had also to bring up the "sports" of that time who during the night waylaid and insulted peaceable inhabitants, pulled up the newly-fixed and as yet unlighted gas lamps, also railings on the new quays at Gilesgate and Crossgate (where the gradients had been lowered), to say nothing of the numerous burglaries and robberies. At any rate, the police reported in 1824 that since their appointment in 1821 they had no less than 785 persons apprehended and confined for breaches of the peace. I do not find any record of fire-extinguishing apparatus until July, 1823; but at a great fire which threatened to burn out the west side of the Market Place in December of that year it is again stated that the two new fire engines were used, and succeeded in saving that part of the town. Since then there are very few references to the apparatus in use from time to time. Now the high pressure of water in the mains renders a steamer unnecessary, therefore we keep a sixteen-manual at the baths for the outlying districts, with a volunteer brigade of eighteen members, a fire escape in the Market Place, a 40-gallons chemical extincteur and hose on wheels in the police reel-house at the town hall, whilst the five higher parts of the city are each provided with a hose-box containing six 75-feet lengths of Shand, Mason's hose, standpipe, key, and nozzle, "Morris" instantaneous couplings, and list of hydrants. The police force comprises a chief constable, an inspector, and seventeen constables. Recent legislation, involving the reporting on licensed premises for compensation causes increased labour in plans and reports, and this year at the County Licensing Sessions seven licences have been reported in this city for compensation.

Time and space will not permit me to dwell on the Sanitary Department beyond that, since 1900, owing to the efforts

Digitized by Google

of the medical officer of health and the sanitary inspector, this city may now almost be described as a "water-carriage" town, the ashpits having decreased both in number and in size, and the sanitary condition of the city being improved to an enormous extent. The question of education is one that does not afford much interest from the departmental point of view to the municipal engineer, excepting that the enormously increased outlay in problematical systems and their attendant officialism is very often an excuse for the cutting down of the necessary work of public development, maintenance of roads, paths, drains, and other branches of municipal organisation, and it is very likely in the near future to hamper us in Durham. The city has, of course, its town clerk, magistrates' clerk, rate collector, and city accountant, who have also private practice. I, however, notice the tendency of accountants to interfere with the legitimate scope of the municipal engineer, and rather think that this interference with our work by other non-technical officials will have to be met in a very firm manner.

Lighting.

The coronation of George III. was celebrated by the inhabitants of this city placing rushlights and candles in each of their house-windows, and these and the time-honoured lanthorn appear to have been the only means of illumination after sunset. Naturally the idle youth, vagrants, burglars, garotters, and other like evil-doers must have had a rich harvest and happy time, if one judges from the local *Durham County Advertiser*, from whose issues I have culled many facts, and my obligation to the editor is hereby acknowledged. The Mayor of Durham held his court-leet and court-baron in 1814, and a public meeting was afterwards held to consider the riotous conduct in the Elvets, Baileys, and South streets after dark. As a result of this the commissioners decided to put lamps in the streets.

These lamps were to be lighted from September 21 to April 3, and provided with best whale oil and cotton wicks, to burn with a full, clear light from sunset to sunrise, except during the five nights before and two nights after each full moon. It was soon complained that these "children of darkness" referred to made it one of their most popular pastimes to steal or smash the lamps wholesale, and this continued up to 1818, when matters had come to a climax. At 1 a.m. on November 25 there were lighted only one lamp in North Bailey, one in Sadler Street, one on Elvet Bridge, two in Market Place, one at the gaol, none in Silver Street, Framwellgate Bridge, or South Street. This caused the St. Nicholas parish in December to appoint four special constables to assist the city constables in their duties, and also to visit public-houses at ten on Saturday nights to desire landlords not to furnish liquor to idle and disorderly persons. Early in 1823 a public meeting was held to take into consideration the lighting of the city and the borough of Framwellgate with coal gas, "and Mr. West (who has recently lighted Stockton, Richmond, &c.) is to carry out the intentions of the commissioners before next winter." This was accomplished, for it is recorded on January 2, 1824:—"The city was partially lighted by coal gas on Saturday and Sunday last, and wholly on Monday evening. The change which this substitute of gas for oil has effected is perfectly surprising, for we behold a city long notorious for its nocturnal darkness become at once perhaps one of the very best-lighted towns in the kingdom. The street lamps are placed much nearer than is usual in most towns, and this, added to the brilliance of the lights, completely fills our narrow streets. A band of music paraded the streets, and the church bells rang a merry peal in compliment to Mr. West, who has at his sole expense erected the works, laid down the pipes, and provided the lamps, engaging to light the town for the same sum that the lighting with oil has cost, the usual charge for gas in towns possessing local advantages as Durham being from 2*l.* 10*s.* to 2*l.* 12*s.* 6*d.* per lamp for the season; but Mr. West has contracted for less than 1*l.* 4*s.*, he supplying all pipes, pillars, services, &c., usually paid for by the commissioners of other towns. Thus Durham has exchanged a light barely sufficient to render darkness visible for one of great beauty and brilliancy without having been at one farthing expense."

In 1841 the first gas company was formed, the undertaking being purchased from Mr. West by gentlemen who were all members of the Corporation, and the vendor quite expected it was being sold to the city. An opposition company was commenced—the Coal Gas Consumers' Supply Company—but this was eventually merged into the above company, and the whole concern transferred to the present company in 1873, who extended the works and area of supply, which is now as follows:—Area of supply, about 33 square miles; houses supplied, 4,507; gas made in 1908, 126,398,000 cubic feet; sold, 100,610,000 cubic feet. There is a special carburetted water-gas plant, by Humphreys & Glasgon, capacity 200,000 cubic feet per day. The price of gas is 2*s.* 9*d.* to 3*s.*, according to quantity used. The company can charge 1*s.* per 1,000 extra for outer districts, but only charge 3*d.* The greatest difficulty over practically the whole area is caused by subsidences due to colliery workings. The company also has a sulphate of ammonia plant. At the end of 1908 there were 1,148 gas cookers and heaters out on hire, notwithstanding the fact that so many residents have their coal supplied free. Up to the year 1902 the city had been lighted by flat-flame burners, one-half of the lamps being extinguished at midnight from October to April, and three-quarters extinguished altogether from May to August, the number of lamps being then 285 5-feet and ten 10-feet burners, and the amount paid per 5-feet lamp being 3*l.* 4*s.* per annum.

The company met us very fairly and agreed to convert all lamps into incandescent burners within a stated time, and to provide all lighting and upkeep as before and mantles, the lamps to be all lighted throughout the year from sunset to sunrise (but one-half to be extinguished at 11.30) at a cost of 3*l.* 0*s.* 6*d.* per lamp per year, and including the newly-added area, there are now:—

	£	*s.*	*d.*
360 ordinary burners, about 3½ feet per hour, 60 to 80 yards apart . . . each	3	0	9
10 four-burner lamps, special Welsbach, each	16	10	0
2 public clocks . . . . . each	16	0	0
3 special single-burner high-pressure lamps in Market Place . . . . each	16	18	0

these charges including all maintenance, attention, and replacements of every kind.

Electric Lighting.

Early in 1901 the Council leased their powers for twenty-one years to the Durham District Electricity Company, and this company's interests were taken up by the County of Durham Electric Power Distribution Company, having their generating station at Carville-on-Tyne, near the source of the coal supply. There is a transforming station just outside this city on the north, from which the current is supplied to the Durham station, now a supply centre only, the Babcock & Wilcox boilers, Chandler engines and dynamos not being now in use. The Aykley Heads sub-station takes its supply at 20,000 volts three-phase, forty cycles per second. Here it is transformed to 5,500 volts, and received at Durham city by means of two separate feeders. The feeders are lead-sheathed cables, laid partly solid and partly drawn in through earthenware ducts, the latter having been originally laid for tramway cables. By using this method the cables, which at this part of the route are armoured, were drawn through without again disturbing the streets. At Durham city sub-station the supply is converted to 480 volts direct current by means of motor generators.

The mains originally laid in the city were three-core vulcanised bitumen cables laid solid in wooden troughing; for later extensions three-cored copper, lead and paper-covered cables have been used, laid solid in earthenware troughing. The low-tension feeders are triple-concentric vulcanised bitumenised cables, also laid solid. The parts outlying the city are supplied by means of overhead three-wire lines, in some cases triple-braided cables being used, in others bare conductors with split neutrals.

The pressure of supply in the city is, on the three-wire system, at 240 volts for lighting and 480 volts for power, and all motors above one horse-power have to be connected across the outers. The number of connections to the company's mains in Durham is about 500. The tariffs are:—

Lighting, 3¾*d.* per unit less 5 per cent. discount.
Motive, 1,000 B.T.U. per quarter . . 1.5*d.* per unit.
Next 50,000 ,, ,, ,, . . 1.25*d.* ,, ,,
,, 50,000 ,, ,, ,, . . 1.00*d.* ,, ,,
,, 50,000 ,, ,, ,, . . .75*d.* ,, ,,
Heating radiators, 1½*d.* per unit, if on separate circuit and meter.

Water Supply.

In the opening historical section of this paper it is stated that in 1450 a supply of water was put into the Market Place, the pipes being in 3-feet lengths, seamed butt jointed and burnt and tafted ends, the lead being virgin lead, containing silver, from the bishop's mines in Weardale, some of which are unearthed from time to time. Previous to this the sole

Digitized by Google

supplies of water were, for Gilesgate, from the Hallow Well, and in the Church Fields a little east of St. Giles Church; in the Elvets, as the names imply, water was abundant in shallow wells; for the south side of the city, St. Oswald's Well on the river banks west of that church; for St. Nicholas and the Palace Green, St. Cuthbert's Well on the river banks west of the Abbey Church, and one for the use of the monastic buildings on the College Green, supplied from springs near Southend. On the west side of the River Wear there were the spring near the Prebends Bridge, the South Well below the technical school in South Street (then Southwellgate), the Framwell, about the site of the gasworks below Framwellgate, the Flash or Flass well or spring on the old city boundary to the west of the railway viaduct, and the Neville or Crossgate well behind the Miners' Hall on the North Road, water being sold in skeels for general use at 1*d.* per skeel, a custom surviving till only forty years or so ago. However, in 1818 the water supply in the Market Place pant being bad, and the pant and its pipes being out of working order and repair, it was proposed to fix two pumps on each of the two bridges "where the public could get pure and wholesome water." Considering that some twenty-five to thirty old stone drains and sewers emptied into the river above these points, probably the townspeople thought otherwise. Colliery workings, various sources of pollution, the gradual filling up of graveyards, &c., notwithstanding, these supplies continued in use till 1844, when the Durham Water Company erected works just outside the south-east corner of the city, with pumps and a service reservoir on Mountjoy Hill near, and the city received a supply of filtered river water until 1880, Messrs. T. & C. Hawkesley being the consulting engineers. This company was taken over by the Weardale and Shildon (now the Weardale and Consett) Company, for whom Messrs. Hawkesley still act in a consultative capacity. The Durham area of supply is, roughly speaking, somewhere about fifty square miles, with a total population of 100,000 persons. There are no great difficulties of supply except those due to colliery workings, subsidences, and occasional anxiety owing to districts being isolated, but repairs can now be done under pressure, and, owing to the system of duplicate pipe-lines, most of the districts are not without water for long. The consumption for domestic purposes is about ten gallons per head. The water charges are 7½ per cent. on the rack-rents, and through meter 7*d.* to 2*s.* per 1,000 gallons, according to quantity used, baths and water-closets being charged for in addition. The highest pressure in the city is 160 lb., and the lowest 30 lb. This constant and cheap supply of a soft, pure water, though of a slightly peaty colour, has an important bearing on the health of the inhabitants, most of whom are underground workers. I have to acknowledge the kindness of the gas, water, and electric companies' officials in supplying much of the above detail.

In connection with gas, water, and telephone trenches, for small repairs we charge material and labour, adding about 10 per cent. above net cost to cover establishment charges and other unforeseen costs, except in long trenches, when all are charged per yard run for reinstatement:—

Roads.

	s.	d.
Setts only	1	7
Macadam	0	8
Cobbles	1	6
Setts on concrete	3	9
Wheelers on sand (relaying only)	0	9

Setts	1	6
Asphalte	2	0
New flags	5	9
Kerbs (ordinary 12 inch × 4 inch)	0	6

During the last nine years the total average annual receipts for labour and material, as above, have been 196*l.* 10*s.* 6*d.*

Markets.

The markets and tolls in the city were on more than one occasion handed over to Durham by the bishops and afterwards the privileges withdrawn and granted to the bailiffs of the city or marshal of all the markets in the bishopric, owing, I suppose, to misuse of the proceeds which should have been applied mostly to the repair and maintenance of the principal roads used by the bishop and prior and their retinues. In December, 1821, they were leased to the Corporation, who transferred them to the present Markets Company in 1851. There has been a much-needed and marked improvement in the management recently of the covered market, and it is becoming a prosperous concern. Part of the property between the town hall and the church reverts to the Corporation and Smith's Charities in 1916-7.

I hope that the members of this Institution will forgive me if I have failed in the attempt to place on record the history of municipal life in towns 100 years ago, as exemplified by that of the place of our first annual meeting. An attempt has been made at originality of treatment rather than showing you so much important municipal work at so much cost. Plans and specifications will be hung up in the town hall for your inspection to show how our work is and has been done, and I can only hope and trust that your visit will be one you can look back on as having combined both pleasure and profit.

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *American Architect* contains an article by Professor W. H. Goodyear on "The Architectural Exhibition at the Brooklyn Museum," which, whilst eulogising, and perhaps justifiably, the collections and surveys of the Brooklyn Museum, is also to some extent a fighting article on the Professor's favourite object of research, the refinements or, shall we say, abnormalities, of the setting out of ancient buildings. Some examples are shown of Italian churches whose plans are axially oblique. The principal illustrations of this number of our contemporary are of cottages and small houses.

La Construction Moderne is up-to-date and gives illustrations of docks or garages for dirigible airships at Moisson and at Issy-les-Moulinaux, these being shown with the steel skeletons in position from which the form and construction of the latest development of architecture can be studied. Our contemporary has another racy article on Mont Saint-Michel and the heterogeneous committee charged with the consideration of the reclamation of the Bay and its effect on the Mount.

Deutsche Bauzeitung, from the architectural standpoint, reviews, with some illustrations, the exhibition of house-equipment at Berlin. There is also a critical report on another new mono-rail system of transport.

Het Huis has an illustrated article on the history of the Wall Welshuis at Amsterdam, the asylum of the Reformed Church of the Walloons, and another on the picturesque water-gates of Amersfoort.

Der Profanbau devotes practically all its space to an appreciation, with illustrations, of the work of Ludwig Bernoully, of Frankfort-on-Main, a representative modern German architect of the school that relies on simplicity of wall with picturesque complexity of roof treatment for effect. Some of Herr Bernoully's interiors are very charming.

The *Engineering Record* has an article on "The New School Buildings of Cincinnati," which are intended to be of fireproof construction, for which reinforced concrete is used. An interesting account is given of the heating and ventilation plant of the Harvard Medical School, which is remarkable on account of the flexibility of the arrangement of apparatus and the standardisation of the designs in the separate structures.

COMPETITIONS.

AN international competition is announced for the erection of the Polyclinic Institute of Jose de San Martin, Buenos Ayres, Argentina. The author of the design placed first will be employed to prepare the working drawings, and to superintend the whole of the works (unless he should be at the same time the constructor of the same) under the general control of the assessors' committee. The author of the design placed second will be awarded a premium of ten thousand peso nacional (2,000*l.*), and of the design placed third 1,000*l.* The plans must be submitted before December 10. A pamphlet containing the terms and conditions of the competition, in Spanish, may be seen on application at the Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, E.C.

The Lord Provost, Magistrates and Town Council of the city of Glasgow have granted a site in the West end (Kelvingrove) Park for the Scottish Exhibition of National History, Art and Industry, to be held there in 1911. They have also agreed to support the undertaking and to do everything possible to render it a success. The site is most central and convenient of access. The undertaking is also having the keen support of a number of eminent London Scots.

Correspondence

[The Editor will not be responsible for the opinions expressed by Correspondents.]

Angles in Greek Architecture.

Sir,—Will you allow me to state in your columns that since sending the five Greek examples of angle application recently illustrated in *The Architect*, I have collated twenty-eight more, both Grecian, Doric and Ionic, and find that they also are founded on the angles of 67½°, 60°, 45°, 30° and 22½°, either singly or in combination with each other or with the arc of a circle?

This variety of application ensures individuality in design.

It might be supposed that with so many methods of solution any rectangle would submit itself successfully to the process of application, but that is not the case, as may be tested by trying the different methods on forms of rectangle other than those found in these examples.

The curve, as might be expected, enters more largely into Ionic than into Doric design.

I trust to find some opportunity of giving publicity to these illustrations, as I believe they will be found an interesting subject of study to the student of Classic architecture.—I am, faithfully yours,

Edinburgh: August 23. G. S. Aitken.

Brick-Clay a Mineral.

Sir,—I have been much interested in reading Mr. Montgomery's letter in your last issue. Now, Sir, Mr. Montgomery is a gentleman who happens to know what he is writing about. His life, as doubtless you are aware, is spent in connection with the brick and tile industries, and as he is a capable and a good business man, surely his protest should have some weight with the legal gentleman who is responsible for this Budget of Budgets. Mr. Lloyd George may be excused from taking as much notice as we might wish of the complaints of his opponents, but when one of his own hard-worked supporters, and an authority at that, raises such an important point, then the legal training of this gentleman ought to serve him in good stead, and he should weigh the question most carefully. I am afraid the hon. gentleman has got into the unfortunate position of no consideration, no surrender, and he will be in the proud position of ruining an important industry, and by this means hastening the political death of his own party. Whatever happens, Mr. Montgomery is to be thanked for his effort, and should even now at the last moment his protest be successful he, with your aid, will have earned the thanks of all engaged in clay-working, as is the case of yours obediently,

Clayworker.

Highgate, London, N.: August 23.

Sir,—Montgomery knows and says brick-clay is not a mineral; the highest legal gentlemen of the land have said all along that this is so. But a David has arisen—a great legal light! goodness gracious, a Lloyd George; and he says all these gentlemen are wrong. Why argue, then? Why write letters, Mr. Montgomery? How futile; what waste of time and ink! All we can hope and pray for is plenty of backbone to the House of Lords, and then, Mr. Lloyd George, take your pension and, as Uncle Sam would say, "Git!" Nevertheless, thank you, Mr. Montgomery, and thank you, Mr. Editor, for permitting the growl.—Your obedient servant,

A Worker in Clay.

From the Black Country: August 24.

The Homeland Association, Ltd., have recently issued a handbook entitled "Where to Stay in the West Country" (1*s.* cloth and 6*d.* paper), which contains the result of a survey by the Homeland Association of nearly fifty towns and districts in that section of the west country served by the London and South-Western Railway, a survey made from both the visitor's and residential points of view. A second volume to complete the survey of the west country will shortly be issued, and cannot fail to be of value.

GENERAL.

The Beckenham Education Authority are about to erect an elementary school for 500 children in Witham Road.

The Officials of the London County Council and the Lambeth Borough Council are conferring as to effecting changes in Belvedere Road, which will make it a more imposing thoroughfare when it has to form the southern "front" to the new county hall. This road is to be widened, and it has been decided to plant it with trees, which will be provided by the County Council and afterwards maintained by the Borough Council.

The Plans for the new recruiting office that is to be erected on a site now being cleared in Great Scotland Yard are being prepared, and when the building is finished it is expected to be a model of its kind. The present inconvenient quarters for the London recruiting district are at St. George's Barracks, in the rear of the National Gallery. It is stated that several of the more important centres will have new buildings.

The Plans of the chapel for the Order of the Knights of the Thistle having passed Edinburgh Dean of Guild Court, the preliminary arrangements in connection with its erection have begun in Parliament Square, Edinburgh. A hoarding has been erected around the portion of St. Giles's Cathedral to which the chapel is to be added, and no time will be lost in commencing to build the actual structure.

The South Metropolitan Gas Company state that as a result of their experiments with a new inverted burner, designed especially for street lighting, they are able to make a substantial reduction in the charges for the maintenance of street lamps fitted with the new burner, which, it is declared, gives a light of 120 candles compared with the 80 candle-power of the old burner.

An Estate of three acres recently acquired by the Council of the Hackney Young Men's Christian Association at Stamford Hill, including two large houses utilised as an Association institute and hostel, will be formally opened on September 18. The scheme provides for the erection of a large, well-equipped gymnasium and additional residential accommodation for at least fifty young men.

A Local Government Board Inspector held an inquiry on Saturday into an application by the Weybridge Urban Council for a loan of 5,000*l.*, the money to be used for the purchase of the common and heath from the Poor's Land Trustees. The proposal was strenuously objected to by the cottagers, who possess a right to take the land for spade cultivation.

An Effort is to be made to raise 3,000*l.* to defray the cost of completing the restoration work at Rochester Cathedral which was begun under the direction of Sir Gilbert Scott.

The Vice-Chancellor of Oxford has received an intimation from Mr. J. B. Carrington, of Hampstead, that he will contribute to the University 160*l.* for the completion of the carving in the coffers of the gallery niches in the New Schools, according to a design and estimate furnished by Mr. T. G. Jackson, R.A. Mr. Carrington has already contributed sums towards the decorative carving in the Schools amounting to over 550*l.*

The Surveyors of the local authorities interested having reported that the north abutment of the old bridge at Stirling is in need of repairs, and the whole structure requiring a general overhaul, a committee recommend that application be made to H.M. Office of Works to have the bridge and its approaches protected under the Ancient Monuments Protection Acts. If this course is not taken the committee further recommend that the surveyors submit a joint report and estimate of the cost of the work to be executed.

Mr. John A. Grainger (of Messrs. Grainger & Little, architects, Melbourne, Australia), formerly chief architect of the West Australian Government, has been making an inquiry into the architectural division of the Public Works Department, Victoria, for the Premier (the Hon. J. Murray). Mr. Grainger has suggested various reforms for carrying on the departmental work, and speaks very highly of the previous work done by the department.

Messrs. William Hodge & Co., Edinburgh and Glasgow, will shortly publish a work entitled "Construction, Equipment and Management of a General Hospital," by Donald J. Mackintosh, M.B., M.V.O., medical superintendent of the Western Infirmary, Glasgow. The author has made a special study of the theory and practice of hospital construction and administration. Besides plans of the most approved types of wards and auxiliaries, the book contains over sixty carefully reproduced illustrations showing wards, operating theatres, laundry and special departments, all kinds of hospital furniture and requirements, &c. The price will be 10*s.* 6*d.* net.

FORTHCOMING EVENTS.

Saturday, September 4.

Manchester Society of Architects: Visit to Liverpool to inspect the following buildings:—The New Cathedral, Dock Board Offices, and the Hall and Reception Rooms at the Town Hall (1754).

Conference on Housing and Workmen's Trains at Ipswich.

Tuesday, September 7.

Manchester Society of Architects: Visit to the Y.M.C.A. Buildings in Peter Street, Manchester (Messrs. Woodhouse, Corbett & Dean, architects).

Wednesday, September 8.

Berkshire County Offices Competition: Exhibition of Designs for the above at the Dairy Institute, Valpy Street, Reading, September 8 to 18. Admission by ticket only.

Friday, September 10.

Manchester Society of Architects: Visit to the Garden Village a Burnage.

Saturday, September 11.

Society of Architects: Sketching Party to Rochester.

Architectural Association: Camera and Sketching Club, Visit to Guildford and district.

SCHOOLS FOR ARCHITECTS.—II.

UNIVERSITY COLLEGE, LONDON.

THE architectural student who pursues his studies at University College, London, is working under university conditions and has, or may have, before him the goal of a degree as an internal student of the University of London. To attain the degree of B.A.Lond. with Honours in Architecture, the student must first matriculate and afterwards pass the Intermediate examination in the faculty of Arts at the University, and also go through a three years' course in the day school at University College.

This school therefore is intended primarily for younger students, those who have recently left a public school and at the end of their stay there have passed their Matriculation examination and so become undergraduates of London University. During their career at the School of Architecture they are students of the premier college of the University of London, with the benefits of tuition in general knowledge that appertain to university education, and very many of the advantages, beyond mere tuition, that are the accompaniment of a university course, though not perhaps to so great an extent as at the older universities of Oxford and Cambridge, in which the social element is more largely developed than at London. There is a tendency in all schools where technical study of some particular calling is pursued for the students to be too much restricted in their companionship to those of their own profession, and this tends to narrowness of idea and lack of comprehension of other people's point of view, faults very detrimental to an architect.

At University College the architectural student passes some of his time in the engineering school, part in the Slade art school. He learns English, French, German, history, mathematics, physics and hygiene with those who are not going to be architects, and he meets these non-technical scholars in weekly meetings of the Students' Society. Thus his ideas are not restricted entirely to the field of architecture and he obtains the benefit of the education, in its wider sense, that university training affords.

As it is not every embryo architect that aspires to the honour of a university degree, there are in University College two parallel courses—the B.A. degree course and the Certificate course. The training in each is on similar lines, the main difference being that the aspirant to a degree must read for and pass the Matriculation and Intermediate examinations of the University, whilst the Certificate course does not entail this necessity. Both courses are arranged (1) to provide the systematic practical training that is desirable for students before they enter an architect's office; (2) to enable students to continue their general studies concurrently with commencing their technical training. Thus those who take the Certificate course are required to attend lectures on general subjects and advised to enter for the Matriculation examination of the University. In this way recognition is given to the fact that to an architect a good general education, extending at least to the standard of matriculation at London University, is of high importance.

Both courses include (1) a thorough grounding in the details and theory of building construction, and in the nature, properties, and working of materials by means of (*a*) lectures, (*b*) studio work, (*c*) demonstrations (held at the Trades' Technical School, Great Titchfield Street), (*d*) visits to workshops and to buildings in course of construction; (2) lectures and demonstrations in the engineering laboratory dealing with stresses and strains, strength of materials, and steel and iron construction; (3) lectures on the history of architectural development, in which evolution, especially as regards plan, construction and general principles, and its causes, are traced by analysis of and reference to acknowledged masterpieces; (4) architectural design; (5) measuring and drawing out fine examples of old work; (6) lectures and demonstrations in sanitary science, heating, ventilation, &c.; (7) drawing from architectural casts and from the antique or life in the Slade school, or modelling. The three especial advantages to students at University College included in these courses are the demonstrations at the trades' training schools, where actual craftsmen study and work; the instruction in the engineering laboratory, where practical testing with efficient apparatus is seen; and the study of drawing from the antique and the life at the Slade school, where some of our foremost painters have received their early training.

The School of Architecture at University College is a day school, although there are also evening classes, which form a separate section of the College curriculum. But students in architects' offices or who have already had some experience can join any of the day classes and lectures for a term or session.

A young student, fresh from school, who enters at University College is set to work in the studio on drawing of an architectural character and learns his construction from the very first by designing. He is told to look at actual examples and commences at the earliest stage to use his own judgment in making a drawing of a plain brick wall with holes in it. He sees executed arches and then makes his design more or less like those he has seen, thus developing his own individuality from the very commencement of his career. Thus he very soon learns to design architecturally and bases his designs on the sound foundation of appropriate treatment of material and construction. He is not encouraged or allowed to copy drawings of construction, though these are supplied for purposes of comparison and guidance. He of course is taught to draw the Orders, and in this respect there

Digitized by Google

WADHURST CHURCH, SUSSEX.—FROM A SKETCH BY BANISTER FLETCHER.

appears to us a lack of equipment in the College and a deficiency in the method of study. We have said before, and we cannot too often repeat it, that in architectural schools there is generally too great a tendency for students to draw the Orders from printed illustrations. In this way the embryo architect does not realise the effect in the solid of what he draws in line. All study of the Orders should be accompanied by reference to casts, preferably full size, of the actual example drawn.

Measuring old work is encouraged, and the student is set to first measure and draw some part of the building of the College in which he is studying. Most of the work in this branch of study is done during vacations.

In addition to studio work and forming a relief from it, attendance at lectures is obligatory on all students. In the first year this is very largely concerned with general subjects selected under the advice of professors from a list comprising mathematics, mechanics, ancient and modern languages, history, chemistry, physics, geology, &c. The technical lectures in the first year are on building construction and materials, isometric projection, a most valuable method of representing construction, perspective, sketching and measuring. In the second year the study, in addition to studio work, includes lectures on construction, the history of architectural development, lectures on stresses and strains with experimental work in the engineering laboratory and drawing from the cast, antique or life. In the third year the work includes essays on the history of architectural development, drawing from the life or antique, attendance at lectures on sanitary science, heating, ventilation, &c., besides the preparation of drawings and designs required for the B.A. degree and for the certificate.

To obtain either the degree or the certificate a student must submit for approval not fewer than six drawings in each of the following groups:—(*a*) From the cast or life (one example of architectural modelling, or two sheets of sketches from actual buildings may be substituted for two of these studies); (*b*) details and theory of construction; (*c*) drawings of an architectural subject or subjects, measured and drawn by the student. For either the degree or the certificate a candidate must also submit a design for a building from a subject set by the examiners and worked out before the examination.

Thus it will be seen that the three years' course of study in the School of Architecture at University College furnishes a very excellent training for those who intend to enter the architectural profession before they actually start the real experience of an architect's office as pupils or assistants. The school is very efficiently staffed, with Mr. F. M. SIMPSON as professor and Mr. LESLIE WILKINSON as his assistant. The school is at present in an early stage of its career, and the number of students is not just yet very large, which is an advantage to those who join, as they thus receive a larger share of individual attention from the Professor and his assistant. The many-sidedness of the education required by a modern architect is well recognised, and instruction of a very high order is provided in the scientific part of that education as well as in draughtsmanship, whilst the individuality of the future architect is very carefully fostered, and thus ability in design is developed along with a knowledge of practical matters.

The fees for the complete course in the day school are 45 guineas for the first year and 35 guineas for each subsequent year. For architectural classes only the fee is 12 guineas a term; for history of architectural development 2½ guineas a term or 6 guineas a session; for building construction or history, and one day a week in studio 10 guineas a session, or two days a week in studio 15 guineas a session.

NOTES AND COMMENTS.

THE summary fashion in which the House of Commons disposed of the committee stage of the Housing and Town Planning Bill does not augur well for a properly considered solution of many points of difficulty with which so novel a measure is likely to teem. When clauses of such a Bill are put in batches and amendments ignored wholesale, it is clear that there is insufficient opportunity for discussion of what in the opinion of many

Digitized by Google

of our legislators are defects in the proposals of the Government.

THE curriculum of the Architectural Association for its School of Architecture for the session commencing this month has been issued. The system of education hitherto established in both the day school and the evening school is maintained on similar lines as before—studio work both in the daytime and in the evening, with lectures and classes. The ordinary meetings of the Association include papers on "The Architectural Association Excursion to Cheltenham and District, 1909," by F. DARE CLAPHAM, F.R.I.B.A.; "Drainage and Sewage Disposal," by W. D. SCOTT-MONCRIEFF; "Architecture of the Incas of Peru," by G. REGINALD ENOCK, F.R.G.S.; "Varallo, Orta, and Varese," by F. C. EDEN; "A Comparison between English and Continental Ornamental Ironwork," by J. STARKIE GARDNER; "Renaissance Church Architecture in France during the Sixteenth Century," by W. H. WARD, A.R.I.B.A.; "The Life and Work of WILLIAM BUTTERFIELD," by E. SWINFEN HARRIS, F.R.I.B.A.; "The Mediæval House," by J. ALFRED GOTCH, F.R.I.B.A.; "The Life and Work of BRUNELLESCHI," by Professor BERESFORD PITE, F.R.I.B.A.; "The Architecture of Bath," by MOWBRAY A. GREEN, F.R.I.B.A.

THE British Fire Prevention Committee has not only done good work here in the attainment by its experiments of knowledge most valuable to the community, but it has inspired people abroad with a desire to emulate its work, and at the conference of the French Fire Service Association held last week at Caen, when Mr. E. O. SACHS was present, it was decided to form a national fire-prevention Council on somewhat similar lines to those of our own committee. There is one essential difference, however. The British committee is a privately organised affair, supported principally by the contributions of its founders and members. The French Council is to include representatives of the Government departments more immediately concerned, and the conference at which its inception took form was presided over by M. CHÉRON, Under-Secretary of State for the French Navy. M. LÉPINE, Prefect of the Paris Police, who has always taken a great interest in the British committee, and has frequently come over to attend its functions, has consented to act as chairman of the organising commission of the new body. Thus from the first the French Council starts with official recognition and assistance instead of the snubs and cold water that were the lot of the British committee.

THE re-erection of Crosby Hall on its new site in Chelsea is now to be actively commenced, and it is expected that in eight months time or thereabouts it will be ready for opening to the public and for its use by the residents in the University Hostel.

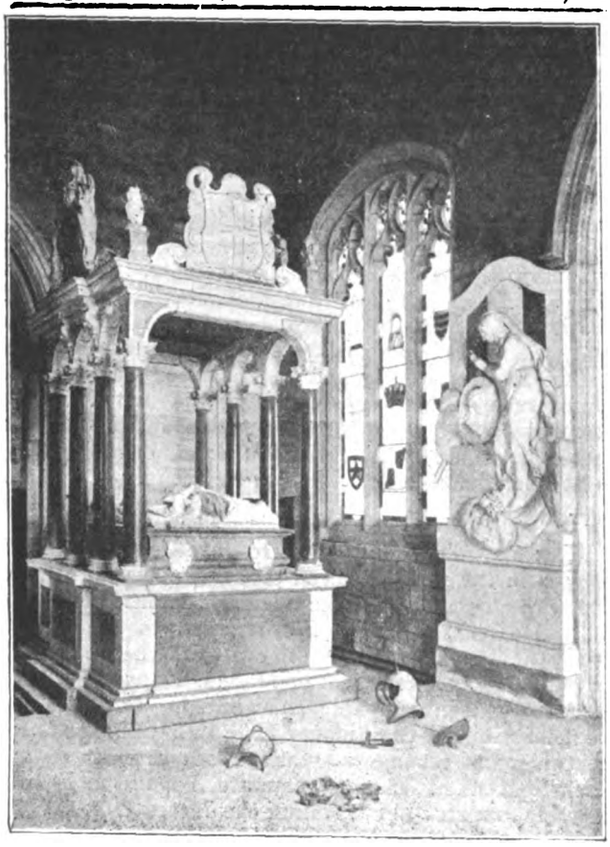
TRADE secrets have a knack of becoming revealed when the light of the law shines upon them, and the latest seems to be that when architects have specified "Austrian" oak they or their clients have really been receiving Japanese timber, which, it was stated in the case of W. W. HOWARD BROS. & Co. *v.* TURPIN'S Parquet Floor Joinery and Wood-Carving Co., Ltd., has during the last three or four years been finding its way into the English market and displacing Austrian or, more properly, Hungarian oak. Of course, there was the usual difference of opinion as to the quality of the wood supplied, the one party asserting that Japanese oak is as good as "Austrian," the other denying this assertion and stating that Japanese oak is not of "Austrian quality." The jury decided in favour of Japanese oak being of "Austrian quality."

WISDOM dearly bought by experience is at length coming to those municipal authorities who in a wave of philanthropic beneficence with other people's money have been rushing into housing schemes. The Manchester Corporation has applied to the Local Government Board for release from its obligation to build houses in place of those to be pulled down for the purpose of erecting three new schools. The houses to be demolished number thirty-six, and within half a mile of these there are 732 empty houses, so the necessity for compliance with the obligations imposed by the Housing of the Working Classes Acts to replace those threatened is not very evident. There can be no doubt that in very many instances houses for the working classes provided by ratepayers' money are not needed, and when built will not let except to those who do not intend to pay their rent.

THE plumbers have once again jeopardised the existence of one of our national monuments. York Minster has narrowly escaped destruction by fire, and only at the cost of some damage from the water used to quench the ignited timbers of the lower roof of the north transept, where the plumbers were engaged in repairing the leadwork. It should by now be recognised that whenever plumbers or other trades requiring the use of fire are at work on a building of great value and importance, there should be a professional fireman on duty ready to at once detect and extinguish an incipient conflagration.

THE committee appointed to investigate the Lake villages in the neighbourhood of Glastonbury in connection with a committee of the Somerset Archæological and Natural History Society has reported to the British Association at Winnipeg that, owing to the amount of work thrown on the hands of Messrs. BULLEID and ST. GEORGE GRAY in compiling and arranging the details of the monograph on Glastonbury Lake Village, it was found inexpedient to resume excavations this summer on the new site at Meare, but the committee hope to make considerable progress in excavating the Meare Lake Village during the summer of 1910. Judging from the discoveries already made and recorded, this new lacustrine site promises to be richer in archæological remains than even Glastonbury.

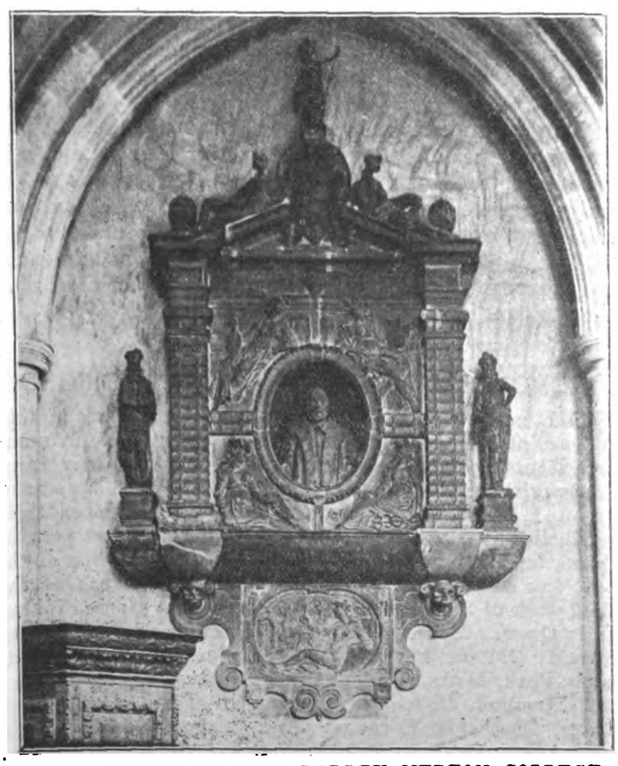
THE news that an hitherto unknown picture by REMBRANDT has been discovered in Newcastle is not devoid of probability. The master was not so greatly esteemed in his own time and his own country that any of his contemporaries or pupils would be inclined to forge his manner and his signature, and it is difficult to imagine that, spite of the skill of the makers of antiques, the peculiarities of REMBRANDT'S technique can be entirely mastered. Nor is the picture likely to be a copy, for if it were it still remains to account for the original. Newcastle is not an unlikely place for a Dutchman's picture to rest in, and there have ever been private individuals who have bought artistic masterpieces because they liked them and intuitively recognised the high quality of work that did not at the moment happen to be fashionable.



NICHOLAS STONE'S WORK AT OXFORD.

TIME has erased much of the architectural work of this sculptor, whose commissions were as extensive in number, if not in importance, as those of his coadjutor Inigo Jones, although he did not attain the age of this eminent architect. The veil of mystery which has enveloped their productions has yet to be fully lifted, and it is just possible that a key to the solution is a thorough investigation of the part taken by Stone, whose record embraces much of the chief work of Jones, such as the Banqueting House, Whitehall; Queen's House and terraces, Greenwich; York House, Strand; Old St. Paul's Cathedral; Somerset House; Oatlands Park, Berks.; Windsor Castle; St. James's Palace; and Hampton Court. The names of Tarthall, Bagshott Lodge, Theobalds, Cornbury Park, Nonesuch Palace, and many others recall to us past glories of the Jacobean Age, all of which held examples of his handiwork.

While there is no certainty that Jones ever visited Oxford, we know that Stone was a frequent traveller, having been to Cornbury no less than thirty-three times in two years, 1631-33, for the Earl of Danby. His cousin, Gabriel Staces, acted as his agent there, assisting him also on the Fountain



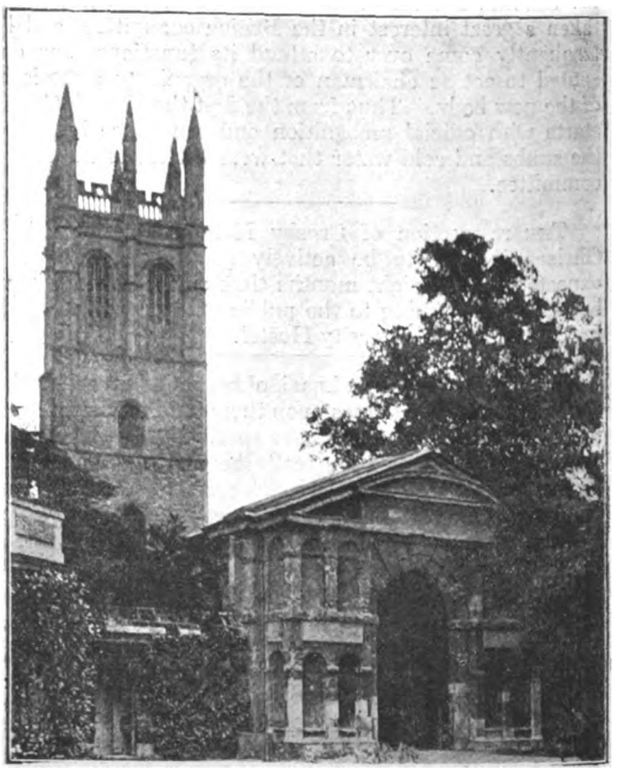
Digitized by Google

at Somerset House in 1636 in conjunction with Hubert le Sueur, and at Greenwich the following year. Is it possible, therefore, that he was associated with Laud's alterations to St. John's College, Oxford, which works were in progress during 1631 to 1635, since we know that Le Sueur, with

TOMB OF WILLIAM, 2ND BARON SPENCER, GREAT BRINGTON CHURCH.

whom he was acquainted, executed the bronze figures there from an account in the Record Office, and that Heylyn may be mistaken in ascribing the work to Jones? St. Mary's Porch was executed in 1637 at a cost of 230*l.* for Dr. Owen,

MONUMENT OF THOS. BODLEY, MERTON COLLEGE CHAPEL, 1615.



Chaplain to Archbishop Laud, and is from Stone's chisel, but the design has been similarly attributed to Jones without any apparent foundation. One has only to compare a few of the earlier monuments such as that to Lord Chief Justice Coke, at Tittleshall, Norfolk, to see that the *motif* is the same although the porch at Oxford is on a much larger scale. It is curious to note, too, the preservation of part of the fan vaulting of a previous Gothic porch; two of the pinnacles are also retained rising above the twisted columns

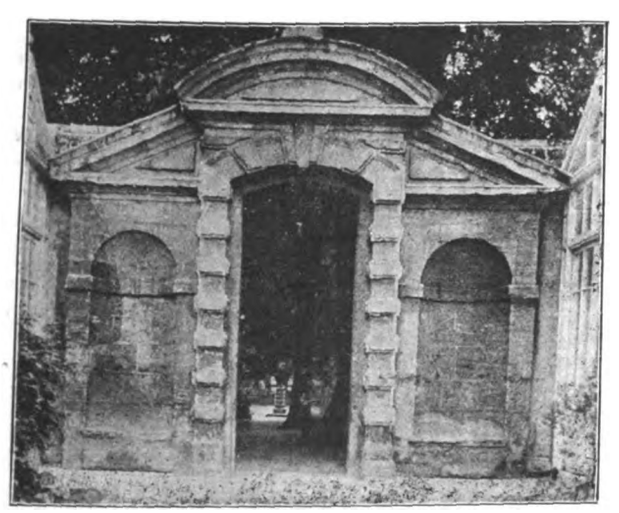
MONUMENT OF JOHN BANKS, 1654.

and cornices of the Renaissance addition, indicating that the original porch was of greater projection. Stone had previously used twisted columns in 1619 in the tablet to Dr. Wright at Sonning-on-Thames. The inference, therefore, is rather in favour of Stone having also designed the porch.

Some work was done at Christ Church in 1632 for which

NORTH GATE WITHIN PHYSIC GARDEN, OXFORD.

Dr. Fells, then Canon of Christ Church, paid Staces in two amounts the sum of 69*l.* There are two works of this date in the cathedral, viz., the west window to Charles Banks, Prebendary of Windsor, by Abraham van Linge, and a



Digitized by Google

mural tablet immediately beneath to John Weston, which is more probably the commission; the vaulted staircase is, of course, of later date, about 1640. On the south aisle wall is a delightfully executed cenotaph to Sir John Banks, deceased December 28, 1644, which John Stone records

MONUMENT TO HUGO BARKER, NEW COLLEGE CHAPEL, OXFORD.

having made in 1654 for 50*l*. The freedom of the treatment of this cartouche form of tablet, and the nice quality of the carving of the angels' heads anticipates the Grinling Gibbons work of twenty years later. Comparing this with the Merton College example carved by his father in May, 1615,

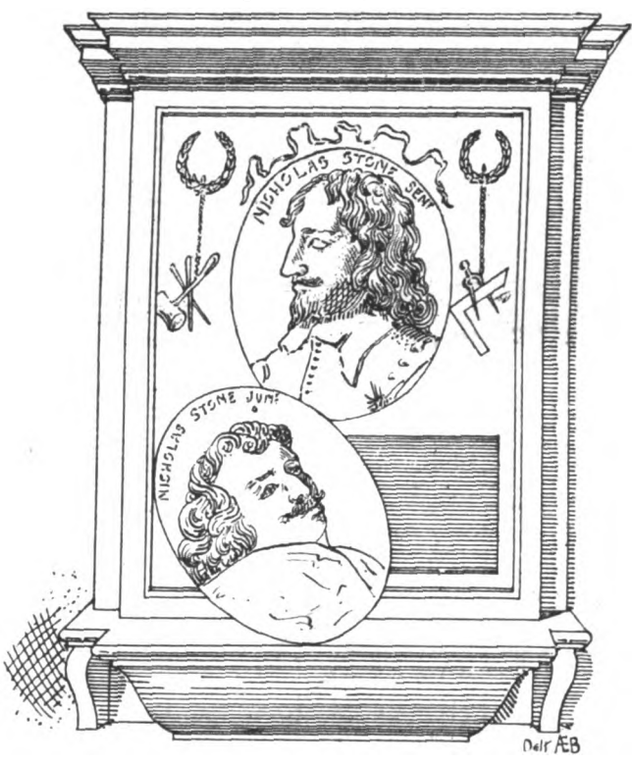
THE EAST GATE, PHYSIC GARDEN, OXFORD.

to Sir Thomas Bodley, there is a marked contrast in design. The latter is rather more Jacobean in character and has some points in common with the Sutton tomb in the Charterhouse, which, though on a much smaller scale, was his joint work with Jansens in this same year, the receipt being dated November 24. "Mr. Hacwell of Lincoln's Inn" paid Stone 100*l*. for the Bodley tomb.

Dr. Hugo Barker's monument in New College Chapel was made in 1632. It is of less interest from the point of design; the bust is placed in a black marble niche surmounted by the coat of arms and crest of the professor and the inscription, with plain festoons hanging down on each side; while the monument executed two years later to the two sons of Sir Thomas Lyttleton exhibits another phase in mural decoration, the sons being carved about one-third full size as bearers to the inscription, which describes the nature of their death by drowning in the River Cherwell. Both these examples were made for the sum of 50*l*. each.

Staces superintended the setting up of the altar tomb to Sir William Stonhouse at Radley-by-Abingdon, receiving some of the money towards the total cost of 120*l*. from Lady Stonhouse. This was originally highly coloured and painted, excepting the skull beneath the arm of the surviving son, Sir George, the third baronet, who kneels at the head. Sir John, the heir, died through grief the following year to his father, although the Lady Elizabeth survived until 1653, but the effigy would appear to have been executed previous to her decease. It was probably into this family that John Evelyn's son was married in 1680 to Mrs. Martha Spencer, daughter of Sir John Stonhouse. The arms of Lady Elizabeth are, POWELL, *three griffins' heads, gules, or, a chevron, vert.* A fuller description of this tomb, with illustrations, is to be found in Mr. Bullock's book on the subject of this sculptor's work.*

Cornbury Park, near Charlbury, forming part of Wychwood Forest, also known as Blandford Park, covers an area of over 5,000 acres. In the reign of Elizabeth the property belonged to the Earl of Leicester, and subsequently to the Earl of Danby, Lord Danvers, who added considerably thereto. Stone's "covenant of acord" for the "desine" of this house, including the three gates to the Physic Garden



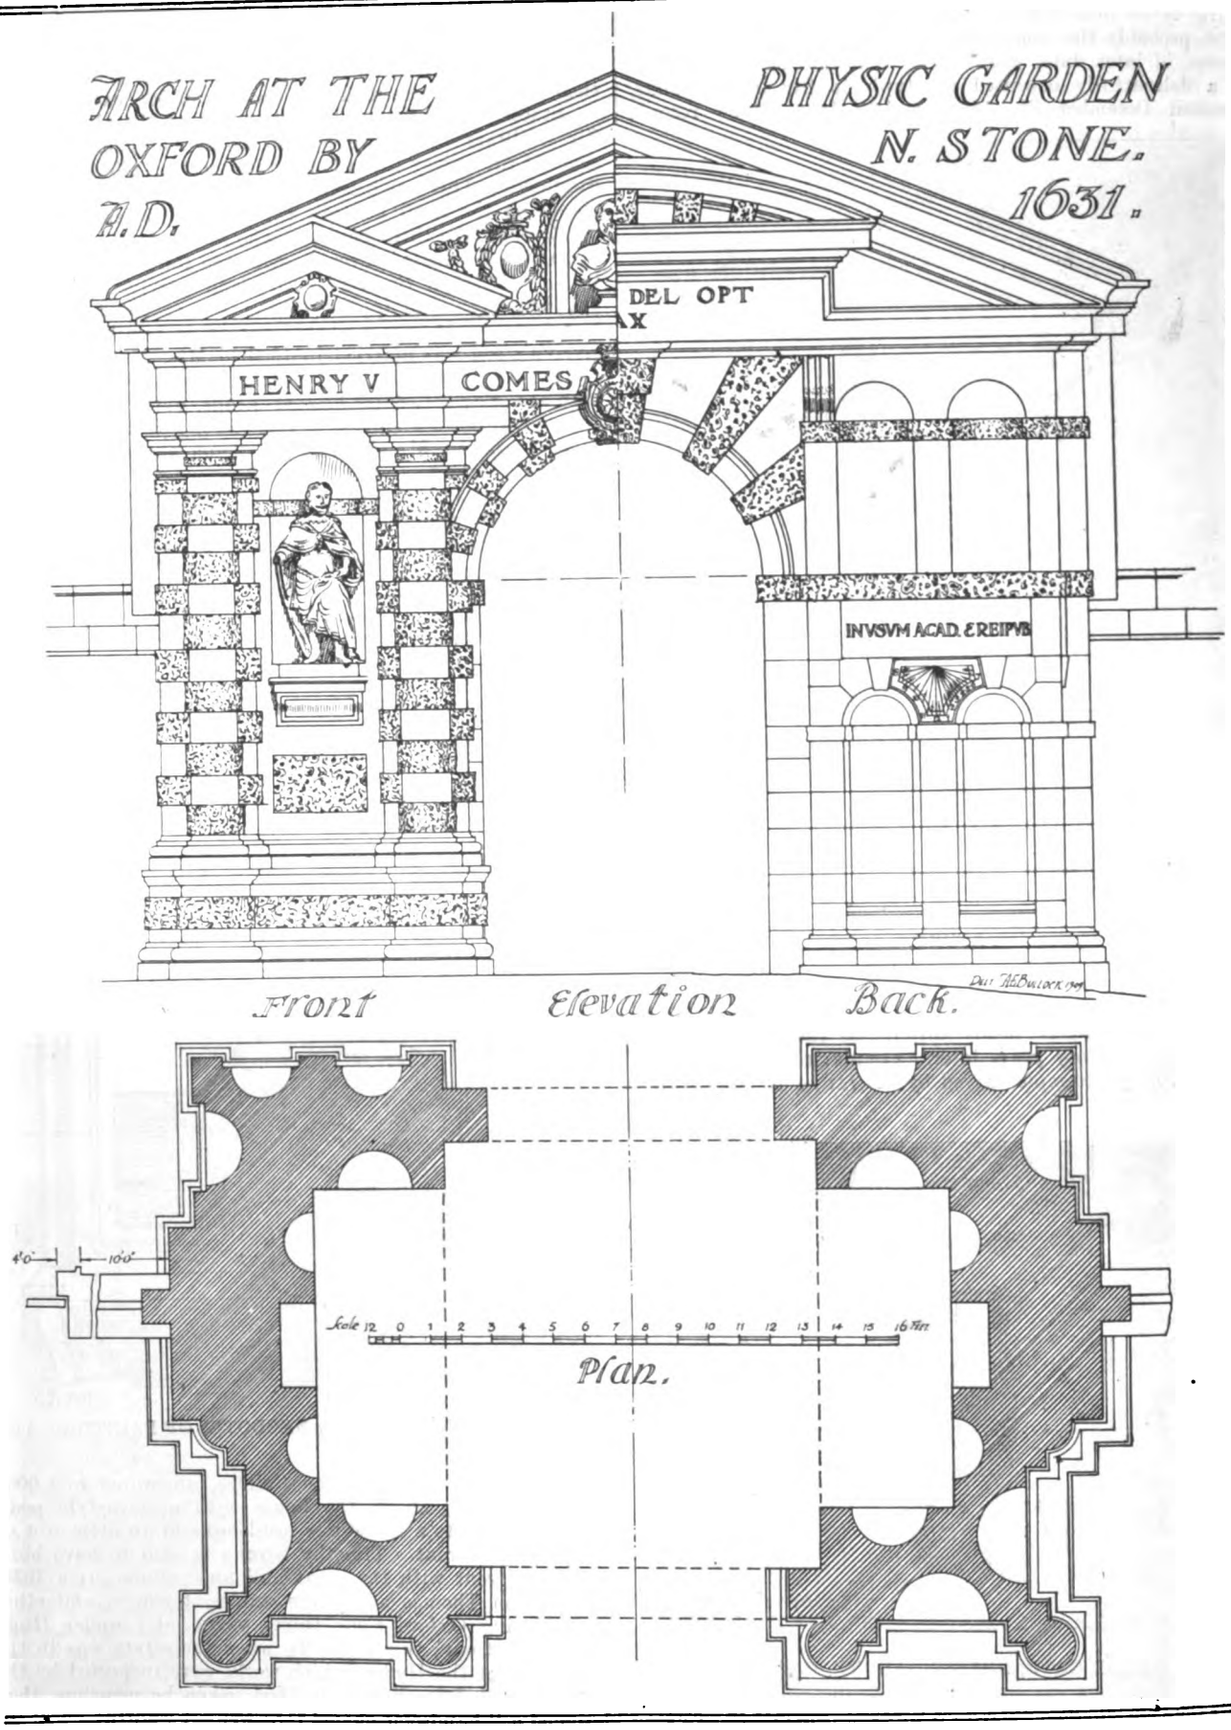


PLATE FROM WALPOLE'S "ANECDOTES OF PAINTING," 1762.

at Oxford opposite Magdalen College, amounted to 1,000*l*. Neale's drawing shows the house with a tetrastyle pedimented portico to a two-storey residence and an attic over on the principal front. Timothy Strong is said to have built the south front with the great hall and cellars, circa 1630, and his son Thomas added the stables, terraces, and other works facing Oxford some thirty years later under Hugh May's directions; this would be when the estate was in the occupation of the Hydes, which works were inspected by the architect and John Evelyn in 1664, when he mentions they designed a "handsome chapel that was yet wanting." With the exception of the chapel, very little of these additions now remain, the most modern portion being added by Mr. John Belcher, and a great part of the old work remodelled for the present owner Mr. Watney.

The three gates to the Physic Garden, of which Jacob Bobart, a German, was appointed the first keeper, are still in a good state of preservation. The principal one is placed at the entrance and has two figures in Roman armour in niches facing the High Street, that to the left evidently intended to represent Charles I., while a bust of the Earl occupies a smaller niche in the pediment, with escutcheons

* *Some Sculptural Works of Nicholas Stone.* (Batsford.)

Digitized by Google

bearing arms on each side, and one carved on the keystone of the main arch beneath. On the south side are painted two sundials, their gnomons having perished. The treatment of the elevation here is rather different, having a curved cornice within the pediment, probably to be in keeping with the design of the other two arches flanking the square of the garden to the east and west. These latter are less ornate and rather smaller, calling for no special remark beyond the curious design of the pediment and rusticated arched opening.

From the agreements Nicholas Stone made with his workmen it would appear that he made use of a quantity of Oxfordshire stone called " Keten " (not Ketton in Rutland), employing one Spadman, a mason and brother to Thomas Spadman, cook to Lord Danby, to carve and deliver 20 tons to a certain wharf in 1632, and further consignments for Windsor Castle during 1633-4.

Stone's patent as Master-Mason and Architect to Windsor Castle is dated April 21, 1626, " for all our Buildings and Reparations," in the room of William Suthis, being paid quarterly at the rate of twelve pence per diem at the " Feasts of the Nativitie, of St. John Baptist, St. Michaell the Archangell, the Birth of Our Lord God, and the Annuntiation of the Blessed Virgin Mary," which quaint phraseology is to be found in the original wording of the patent in Rymer's " Fœdera." Of the other workmen employed by

Digitized by Google

Stone, mention is made of William Hunt, John Thorne, John Bartholomew, Thomas Richardson, Mr. Heroon, Herbert Klellen, Mr. Woberall, Mr. Wilson, Mr. Hamton (Hampton?), Van de Stene, Robert Pooke, and Thomas Palmer.

A number of monuments were also sent to the churches in neighbouring counties, notably in Warwickshire, Northamptonshire, Bedfordshire, and Berkshire; by far the greater number, however, are to be found in Norfolk, Suffolk, Herts, Essex, Kent, and Middlesex. An example at Wroxton-by-Banbury to Sir William Pope is worthy of note from the lightness of the design for an altar tomb 25 feet high, while another at Great Brington Church, near Althorp, to Sir William Spencer, 1638, is similar, the canopy being supported on eight columns. In the same church his son John executed the monument to Sir Edward Spencer in 1656 for 64*l.*, and others subsequently to the grandparents of Col. Osborne at Campton, Beds., in value 200*l.*, and at Nonbottle Church, Northants, to a Mr. Criswell for 100*l.*, and two tablets at Sonning-on-Thames, where his father's monument to Dr. Wright is, viz., to Lady Clark, and an eagle and escutcheon. The monument to Baptist Viscount Campden at Chipping Campden, Glouc s, is said to be by Nicholas Stone, senior, and it is possible the Spencer tomb at Yarnton and that of George Reed at Bredon are from his chisel, the latter having a striking similarity in certain details to the examples at Wroxton and the Charterhouse.

At Cornbrook is another good example of altar tomb by this sculptor, namely, that to Sir Richard Verney of Compton Verney; there is no canopy, the effigies being recumbent upon the top slab as at Westminster in the Buckingham and Villiers monuments. The cost of the Verney example was 90*l.*, and was erected about 1630. It is thought the Lucy monuments at Charlecot are by Nicholas Stone. The effigy of Sir Thomas Lucy has the reputation of being by Bernini; it was more probably by Nicholas Stone, junior, who worked in the atelier of Bernini when in Italy; he carved the figure of Lady Berkeley of Cranford, which was either sent in advance or brought over by him upon his return to England in 1642. The monuments to this latter family are at Berkeley, Gloucestershire. The little son of Sir Robert Nanton is a Northamptonshire monument by the elder Stone, and that at Stow-of-the-Nine-Churches to Lady Elizabeth Carey, which was executed for Lord "Davers" (Danvers) for 220*l.*, where another was subsequently placed in 1619.

Stone's work increased very much about 1636, when he added to his land in Long Acre a further area belonging to Francis, Earl of Bedford, in addition to that he already held of Sir Wm. Slingsby. About 1642 he sent a mural tablet to Berkhampstead parish church to Thos. Baldwin, which is of refined taste in design although the inscription is now very difficult to read. In this same church, in the chancel, is a quaint undated tablet to John and Jacob Moravio. There is an Italian touch about it not unlike the tomb to Elizabeth Drury at Hawstead Church, Suffolk. Time with his scythe is a tasteful terminal if the general construction is a little weak.

There are many other works referred to, as to the whereabouts of which no clue is given in his diary, and one can only speculate that where Inigo Jones was building Stone would take some part, either in the entrance gate piers, as at the residence of the Earl of Wemyss at Stanway, Glouc., occupied by Sir Paul Tracy in the reign of James I., or the chimney pieces, as at Wilton and many other seats. His work carried him far afield, and his workmen were numerous, while in addition his three sons were kept in active employment, so that his notoriety was as great if not greater than any other sculptor of his age. It may be said, too, with very few exceptions, that the standard of refined quality by which he won his name was maintained throughout his career and continued after his death in 1647 by his two surviving sons John and Henry. During the Civil War he remained politically neutral, quietly executing his commissions in his yard at Long Acre, with the exception of the occasion when he assisted Inigo Jones to bury his treasure first at Scotland Yard and afterwards in Lambeth Marsh. John Stone took a more active part, however, by joining the forces of the Royalists, and after narrowly escaping a hanging, fled to France. On his return to England he published a book entitled "Enchiridion of Fortifications, or A Handful of Knowledge in Martial Affairs."

He was the last survivor of the family, and was buried in 1667 with his father and brothers in St. Martin's-in-the-Fields Church; the tablet, which was kept in repair by a near kinsman, Charles Stoakes, does not now appear to exist.

LOADS UPON ROCKS AND SOILS.

MESSRS. GARBUTT & MUNBY write as follows in the "Journal" of the Royal Institute of British Architects:—

It has been suggested to the Science Committee that the available information as to the weights which, under varying conditions, may be safely put upon the different rocks and soils met with in the construction of foundations is both meagre and conflicting, and that if individual members of the Institute would put at the disposal of the Committee the various detailed particulars they must possess as to actual experiences upon their own work, it might be possible to collate the whole and issue the result for the benefit of members generally.

The records of laboratory experiments as to the crushing of small pieces of stone, while useful in connection with building construction, are sometimes misleading if used in considering the bearing power of those materials for foundation purposes. And of course there are many materials, and those probably the most common, that cannot be usefully dealt with at all upon a small scale.

In view, among other things, of the facts (1) that a large uniformly loaded surface will generally sustain a greater load per unit of area than a small one, (2) that the amount of moisture in the soil may greatly affect its value as a foundation, (3) that the possibility of the lateral escape of the load-carrying material is an important consideration, (4) that the compressibility of materials varies much, and (5) that, under some conditions, sliding of the building upon its foundation or of underlying strata upon one another may be anticipated, it is clear that a mere tabulation of the weight-bearing capacity of rocks and soils at so much per square foot cannot be a trustworthy guide in practice.

The Committee therefore invite all who have items of information in their possession to send them to us for the purpose indicated above. It is especially requested that all notes sent be as full as possible, and that all facts likely to affect the results be mentioned. It will be helpful if the spot to which particulars refer can be named, and particulars of the strata both above and below the actual foundation level, together with mention of the depth of foundation below the surface, are desirable.

As this is a subject of great importance to all architects, we venture to hope that there will be a ready and generous response to this appeal. The names of architects and of buildings will be regarded as confidential when such a course is desired by the correspondents; and if the information obtained by the Committee proves of sufficient interest to justify the issue of a report, a draft of the proposed document will be sent to each contributor of material used.

MATT. GARBUTT,
ALAN E. MUNBY,
Hon. Secs. Science Standing Committee.

ILLUSTRATIONS.

MONUMENT TO THE LATE MARQUIS OF SALISBURY, WESTMINSTER ABBEY.

THE national memorial to the late Marquis of SALISBURY in Westminster Abbey was uncovered four weeks ago without any ceremony. It stands under the north-west tower, on the site of the southern screen and close to the allegorical monument by WESTMACOTT to CHARLES JAMES FOX. The Marquis of SALISBURY monument comprises a bronze recumbent statue on a pedestal of Belgian black marble, eight Biblical figures, and six figures of early members of the CECIL family. Lord SALISBURY is represented in his robes as a Knight of the Garter, with the Collar, and in his left hand he clasps a small cross. Behind the cushion upon which the head rests are shields bearing the arms of Trinity House and the Cinque Ports, the late Lord SALISBURY being an Elder Brother of Trinity House and Lord Warden of the Cinque Ports. At the feet of the effigy there is the badge of the Garter, St. GEORGE and the Dragon, encircled in a wreath of oak leaves, and on one side of the wreath there is the shield of Oxford University and on the other that of Westminster. The coats of arms of the four CECILS who have been Knights of the Garter figure prominently on the pedestal. The six figures of the earlier members of the family are—on one panel, Lord BURLEIGH, Queen ELIZABETH'S High Treasurer; Sir ROBERT CECIL, the first Earl of SALISBURY (holding a model of Hatfield, which house he built); and

HOUSE FOR BUSICK E. PEMBERTON, ESQ., ON HAREWOOD DOWNS GOLF CLUB COURSE, CHALFONT ST. GILES, BUCKS.

THE accommodation consists of four public rooms, eleven bedrooms, two bathrooms. The house stands on the top of a hill, is built in brickwork covered with extra fine rough-cast and hand-made sand-faced tiles on the roof. Mr. A. J. BATES, of Chorleywood, is the builder.

the late Lord SALISBURY'S father, the second marquis; on the other panel, their wives. The Biblical figures stand in couples at the corners of the pedestal, and represent SAMUEL and ZERUBBABEL, ISAIAH and DANIEL, MOSES and JEREMIAH, ABRAHAM and JOSHUA. The inscription round the top of the pedestal is as follows:—"Erected by Parliament to ROBERT ARTHUR TALBOT GASCOYNE CECIL, third Marquis of SALISBURY, K.G., G.C.V.O., thrice Prime Minister. Born February 3, 1830. Died August 22, 1903. Domine Refugium." The bronze casting was done by Mr. A. B. BURTON, of Thames Ditton, and the masonry work by Messrs. JENKINS & SONS, of Torquay. Mr. W. GOSCOMBE JOHN, R.A., was the designer and sculptor.

WAREHOUSES, 84-87 CHISWELL STREET, FINSBURY.

THE three warehouses erected for Mr. J. A. CARRAN, furrier, comprise well-lighted basements, ground floor and five floors above. The front elevations are faced with vitrified terra-cotta to the top of the first floor and green glazed bricks with vitrified terra-cotta strings, window dressings and cornice above, executed by the Leeds Fireclay Co., Ltd. The slope of roof in front is covered with green Westmoreland slates, and the flats are constructed with steel joists and concrete, covered with Val-de-Travers asphalte. The windows are fitted with Messrs. HOWARD & Co.'s iron casements, and the same firm have carried out all the steel construction, fire-escape balconies and iron guard rails. The staircases are fire resisting throughout, carried out in accordance with the London County Council's regulations. The pavement lights and stallboard lights were supplied by the Improved Pavement Light Co., Ltd. The strong-room doors were supplied by Messrs. CHUBB & SONS, LTD., of Queen Victoria Street. The general contractors were Messrs. PATMAN & FOTHERINGHAM, LTD., and the architect was Mr. C. E. JACKSON, of Broad Street House, E.C.

UNITED COUNTIES BANK, WALSALL.

THE whole of the capacious ground floor and basement are occupied by the bank. The first and second floors, which have a separate entrance from the street, are let off for offices, and caretaker's quarters are situated on the third floor. With the exception of plinth and entrance doors, which are of polished grey granite, the whole of the front is faced with Grinshill stone. The contract, amounting to about 5,200*l.*, was carried out by Messrs. T. ELVINS & SONS and the desks and fittings by Messrs. T. INGLESANT & SONS, from the designs of Messrs. COSSINS, PEACOCK & BEWLAY, Birmingham.

UNITED COUNTIES BANK, DUDLEY.

THE whole of these premises, situated on an exceedingly narrow site, are occupied by the bank, with caretaker's quarters at back. The front is faced with Leicestershire bricks with dressings of green Quarella stone. The contract, amounting to about 1,600*l.*, as well as all fittings and desks, was carried out by Messrs. J. DALLOW & SONS, from the designs of Messrs. COSSINS, PEACOCK & BEWLAY, of Birmingham.

STIVERS HOUSE AT CHALFONT ST. GILES

THIS house is situated in the centre of open woodland, has four reception-rooms and ten bedrooms. The builder was E. H. BURGESS, of Gerrard's Cross. It is built in Dutch bricks, and roofed with old pantiles, all supplied by Messrs. AMES & HUNTER, London.

THE SETTLEMENT OF THE SAXONS.*

(Concluded from last week.)

TO cast doubt on the story of Hengist and Horsa, some one stated that the names mean horse and mare; and that half-truth has been retailed by successive writers on the subject. But though Horsa means mare, the word was also applied to a cob, and the short-legged, thick-set younger brother we may regard as the pony. With the early settlers in India the Aswa-Medha, or sacrifice of the horse, was the most sacred of all rites. In the Sanscrit Mahabharata and in the Ramayana it is minutely described. Tacitus, in his "Germania," tells that sacred white horses were kept in the groves of Germany at the public expense, and at the close of the eighth century synods in Mercia and Northumbria prohibited horses being sacrificed to Woden. The banners of the Saxon pirates had the white horse worked on them, and they cut white horses on the hills at Uffington, Berkshire, and Westbury, Wiltshire. It remains as the cognisance of Hanover and Brunswick, and is the symbol of Kent. On the hill above Kits Coity House is a boulder called the White Horse Stone, on which it is said Hengist was installed first King of Kent; the stone was lost sight of for some years, but has again been brought to light. The White Leaf Cross at Princes Risborough is traditionally stated to have been fashioned as a memorial of a successful battle fought there by Hengist and Horsa.

Although in the Chronicle Hengist and Horsa are associated with the Angles, they are generally regarded as having been Iotas (Jutes). After the Jutes came three hordes of Saxons—Ælla and his three sons in 477, who founded Sussex; Cerdic and his son in 495, who established the kingdom of Wessex; and in 527 the party who founded Essex, which then included Middlesex; and finally came the Angles in three companies. The first, about the year 527, gave name to East Anglia; in 547 Ida took possession of North-humbria, later divided into Bernicia and Deira; and about 586 Crida established Mercia; and these seven main kingdoms are termed the Heptarchy.

Later as various kings conquered their neighbours they were termed Bret-Waldas or Weilders of Britain.

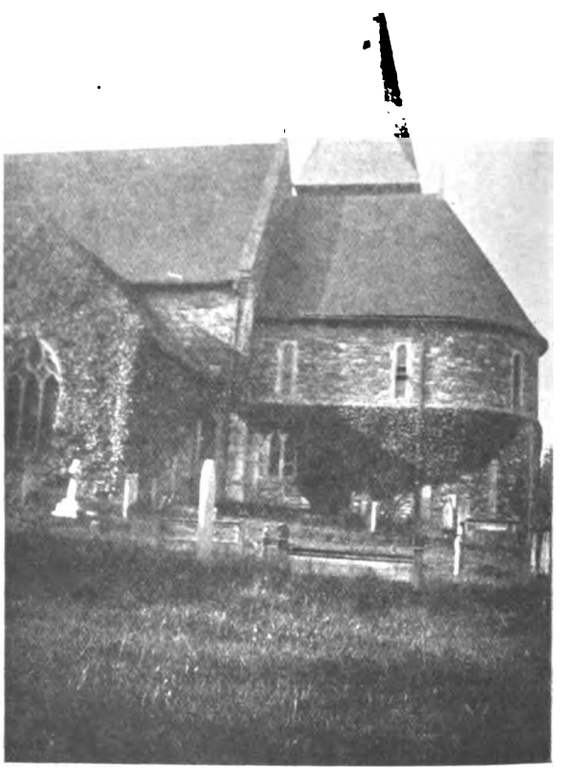
The Anglo-Saxon language was derived from the Gothic, was spoken by the Plats, or Low Germans, and was brought here by the Jutes, Saxons and Angles; and modified in spelling and pronunciation, and extended with words from other tongues, it is the language we speak to-day. At first they had a Runic alphabet consisting probably of only sixteen signs; gradually it was increased to twenty-four, v and z not included; but the simplicity of the Roman alphabet soon caused many of the letters to be adopted, and in the revised alphabet j, k, q, v and z had no place; a few combined letters and abbreviations, however, were introduced, and later k and q were occasionally used. The earliest specimen of English is the maker's name in Runic characters on a gold cup found at Schleswig, and ascribed to the middle of the fourth century. Very few Anglo-Saxon Runic stones have been discovered, and seemingly only one in England. It was found in Nottinghamshire about 1618, and William Grimm gives the inscription as Rices Dryhtnes, meaning the dominion of the king, and it is supposed that the cross was a boundary mark.

In 565 or 560, according to Bæda, Æthelberht succeeded to the kingdom of Kent. He married Bercta, already a

* Read at a meeting of the Upper Norwood Athenæum by W. F. Harradence.

Digitized by Google

Christian, and he gave her the church outside Canterbury which Hasted quotes as St. Mary's, and states that her chaplain, Bishop Luidhard, rededicated it to St. Martin. At the coming of St. Augustine Æthelberht was baptized on June 2, 597, and gave to Augustine the little chapel of St. Pancras; and Arthur Penrhyn Stanley cites the legend that the "Old Demon" tried to pull it down, and the marks of his claws are still shown. Pope Gregory wrote to Augustine that heathen temples were not to be destroyed, but turned wherever possible into Christian churches; oxen were not to be killed for sacrifices, but for feasts for the poor; and so many Pagan customs, including the nyd-fyr, which lingers in the lighting of the Paschal candle, were retained and gradually adapted to Christian usage. To assist Augustine, Bishop Paulinus was sent by Gregory in 601, and in 627 he converted Edwin, King of the Northumbrians; and Bæda tells us he first built a little church of wood, and later enclosed it with a larger and nobler church of stone, dedicated in honour of St. Peter the Apostle, and this is regarded as the first church of stone built in Britain, and from it York Minster arose. In 604 Sebert, King of the East Saxons, had been baptized by Bishop Mellitus, but not until 654, when St. Cedd laboured among them, was Christianity established. In 635 King Cynegils and the West Saxons submitted to Bishop Birinus. In 636 Bishop Felix converted the East Angles. In 653 the Middle Saxons, under Peada the ealdorman, received the true faith, and in 655 Bishop Diuma converted the Mercians. Although about the year 650 King Ædelwalch had allowed Dicul and his Irish monks to settle at Bosham, it was not until 681 when Wilfrith, driven from York, was shipwrecked at Selsey and built his wooden church there, that the South Saxons gave up their pagan worship. King Ceadwalla, who died in 689, to enable the Archbishop of Canterbury to visit him without leaving his own territory, granted to him all the manors lying between the Canterbury diocese and Lewes, and so the Archbishop's Peculiars originated.



For many years the Anglo-Saxons had no coinage of their own, small Roman copper money being in circulation. Copying the French, they produced a few gold pieces, followed by a silver coin called the sceat, or penny. In Northumbria the chief coin was the copper stycas, the eighth of a penny. The moneyers were scarcely successful in imitating the Latin inscriptions, but reverting to runes they were more intelligible. These bore the name of Peada, who reigned 655; Epa, possibly Eoppa, the brother of Peada; and Æthelred, of Mercia. Offa of Mercia about 775 introduced the silver penny, the most artistic coin yet produced; and pennies were struck in Kent, East Anglia and Wessex. A few halfpence were also coined, but as a rule the penny was cut in half, and occasionally into quarters, and so the four-thing originated.

Offa's annual grant of money to Rome is regarded as the origin of Peter's Pence. His wife is stated to have been a Danish lady, and so would be the first Dane in Britain of whom we have any record. Her name was Kynethryth, and she was instrumental in the murder of Æthelberht of East Anglia. In 787 King Bertric of Wessex married Eadburga, one of the daughters of King Offa, and "in his days" the first accredited descent of the Danes was made, and the question arises, had Eadburga and her mother anything to do with their coming? Asser states that Eadburga by poison removed everyone the king loved, and unwittingly he tasted the wine and died, and henceforth no queen was allowed to sit on the throne by the king, and they were not even styled queen, simply the king's wife.

Ecgberht fought and conquered the neighbouring kings, and in 827 the Heptarchy was virtually dissolved, though Alfred and Æthelstan had to extend and complete the work he had commenced.

In 865 a Danish sea-king, Ragnar Lodbrog, being wrecked on the coast of Northumbria, was captured and killed by being put into a pit of snakes, and his sons, variously quoted as Guthrum, Inguar, Halfdene and Hubba, and thousands of Danes swore to avenge him. It may be mentioned that sea-kings generally were younger sons whose only inheritance was a sword and a ship. Inguar (Ivar the Boneless) and Hubba took possession of Deira in 866, and in 871 Halfdene and Guthrum were with Bagscag when he attacked Reading; and later Guthrum compelled Alfred the Great to take refuge in the Isle of Athelney. In 878 Hubba, with twenty-three ships, sailed to Devon; and Asser tells that with 1,200 other Danes he met with a miserable death, and the Saxons captured his banner, the enchanted raven, which so revived their courage that Alfred emerged from his retreat and completely routed the Danes. Asser further mentions that in the event of victory the raven came to life, but in this battle it hung down motionless. From the Icelandic Edda we learn that Odin has two ravens, Hugin and Munin (thought and memory), who during the day fly all over the world, and returning at eve perch on his shoulders and whisper to him all that has happened, and one of the titles of Odin is Hrafnaguth, the raven's god. Guthrum in his conquest of East Anglia in 880 was aided by Hrolf (Rollo) the Dane, the ancestor of William the Norman.

Alfred, though often compelled to use the sword against the Danes and others, found time to use the mightier weapon, the pen; and there is little doubt that the compilation of the Anglo-Saxon Chronicle was commenced at his Court at Winchester. Of the seven variants now extant, five had been collected by Sir Robert Bruce Cotton in the days of Charles I. To Cotton also we owe the preservation of the "Song of Beowulf." The MS. is late tenth century, but it is regarded as having been compiled at the Mercian Court by a scôp, or minstrel, between 660 and 680, and Stopford Brooke conjectures it was first sung in the fifth century. Little attention had been paid to A.-S. MSS., and when in 1699 Dr. George Hickes, Dean of Worcester, commissioned Humfrey Wanley to search throughout England for them, in the Archiepiscopal Palace at Lambeth a MS. volume of homilies was found in a parchment cover on which appeared a portion of an Anglo-Saxon poem regarded as earlier than Beowulf. Even then no attention was paid by the authorities, and when the volume was rebound, the cover was destroyed. Fortunately Hicks had copied the fragment, which is known as the "Fight at Finns Burgh." The first native Anglo-Saxon poem "The Miraculous Hymn" was written by Cædmon about 670. Bæda, born about 673, besides writing in Latin had translated St. John's Gospel into his native tongue; the MS. was probably burnt by the Danes; a few of his short poems are still extant, and there are some others by Cynewulf assigned to the eighth century, and several earlier poems not of native origin. Alfred endeavoured to make Anglo-Saxon the language of literature; and several works he translated from the Latin, sometimes making additions to them. His works include Bæda's "Ecclesiastical History," "De Consolatione" by Boetius, the "Universal History" by Orosius, and the "Regula Pastoralis" by Pope Gregory. Original Saxon literature virtually died out with the "Vision of Piers Plowman," written by William Langland about 1362; of late date too is the short story "Apollonius," better known to us by the version in the Latin "Gesta Romanorum." In the translation by the Rev. Charles Swan, it is Tale CLIII., and it is interesting as having formed the foundation of Shakespeare's "Pericles, Prince of Tyre."

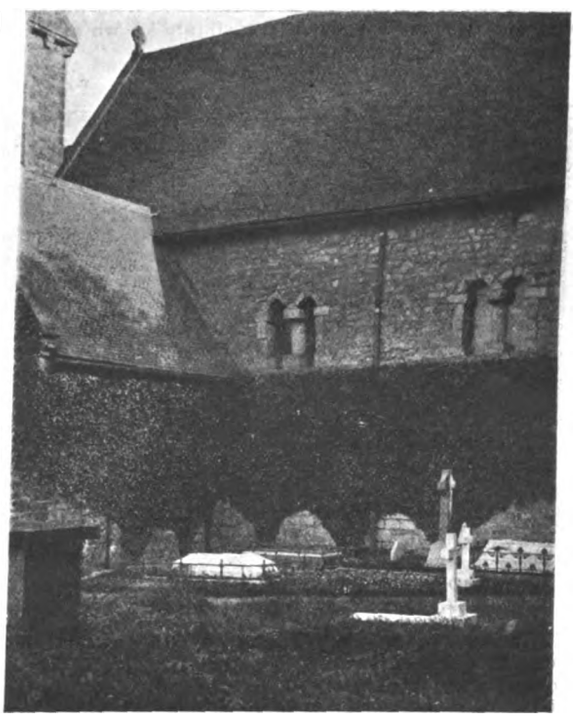
WORTH CHURCH.

Digitized by Google

It was in Alfred's time, 895, that 250 Danish ships entered the Limine, and a ship supposed to be one of them, sixty-five feet long, was found at Northiam in 1822. The Danish and Saxon ships were similar in form; some years ago a Saxon one was dug out of a peat bog in Schleswig, and from Roman coins it contained it is believed to date from the first half of the third century. It is seventy feet long by nine broad.

In the northern parts of Britain the Saxons burnt their dead; in the south they buried their warriors in full military dress, and from the remains considerable information has been derived as to their habits; swords a yard long with double cutting edges have been found, with other arms and various kinds of ornaments.

Alfred's daughter, Æthelflaed, known as the Lady of the Mercians, was the first Saxon who displayed any tactics in war, and places she conquered she retained by erecting burhs or fortresses within them. Commencing in 912 she gradually constructed burhs at Starrat, Bridgnorth, Tamworth, Stafford, Eddesbury, Warwick, Cherbury, Wardbury, Runcorn, Derby, and Leicester; and her brother Eadward the Elder, following her example, erected them at Hertford, Witham, Bedford, Nottingham, Stamford, Manchester, Bakewell, Chester, and Colchester. Eadward in 901 was the first to assume the title of King of the Anglo-Saxons, and it is interesting to note that Eadred in 955 styled himself Cæsar of the whole of Britain.



Eadward's son Æthelstan ascended the throne in 925, and was the first king hallowed at Kingston-upon-Thames. Several foreign princes were brought up at his court, and among them was Haco the Good, King of Norway; and among the visitors was Egil, the Danish skald, who in the Icelandic saga bearing his name writes of Æthelstan. In the massacre on St. Brice's Day, 1002, ordered by Æthelred the Unræd̄ig, or council-lacking king, Gunhild, sister of Swein, although a Christian, was killed. Swein was terribly incensed, and the overthrow of the Saxons soon followed.

Worth.

The early Saxon churches were built of wood, as were the cathedrals at Dunwich and Selsey, where the sea now rolls. The only specimen remaining is the little church of St. Andrew at Greenstead, which Dugdale records was constructed in 1013 for the body of the martyred King Edmund to be lodged in on its return from London to Bedriceworth (Bury). The first stone churches of the Saxons merely consisted of a small nave and chancel, and not until the eleventh century was the cruciform plan adopted. The chief features of Saxon architecture as given by Parker are small windows high up in the walls, quoins of hewn stone alternately flat and on end, flat vertical strips slightly projecting and resembling pilasters, semicircular arches and small triangular doorways and windows; and Freeman says:—"The towers are tall and slender, with small round-headed windows with shafts (sometimes balusters) set in the middle of the wall; towers, however, seldom keep their low four-sided spires, but at Sompting the original capping remains." Saxon work remains at Monkswearmouth built by Benedict Biscop in 674, and in the oratory at Jarrow, which he built in 684. St. Lawrence, Bradford-on-Avon, was erected about 694 by St. Aldhelm, who is regarded as the first Anglo-Saxon who wrote in Latin. St. Wystan's, Repton, has a Saxon crypt with pillars and the two original staircases. The Priory of the Holy Trinity and St. Mary at Deerhurst, founded by Earl Dodo, has some arches stated by Walcott to date from 980, and the adjacent chapel of the Holy Trinity, built by Earl Odda in 1056, has suffered little from the desecration it has undergone. Barnack Church is stated to have been built by Canute, and Lower suggests that he was the builder of Holy Trinity, Bosham. He had a palace there, and in the church his little daughter was buried; the stone coffin containing her remains was exhumed in 1865 by the Rev. Henry Mitchell. The churches at Escomb, Earls Barton, Barton-on-Humber, Lewes, Colchester and many others also have distinctive Saxon features.

The great forest of Andreadsleas stretched for very many miles, and the portion that became known as Worth Forest included the present Tilgate Forest, and in a small clearing a Saxon tribe or family had formed their seat or settlement. Although in Alfred's will there is no mention of Werth being left to his son Æthelward, as has been stated, for his legacy consisted of the sum of 500*l.*, it may be that Æthelward received it by deed of gift, for we know that it was a royal manor in the days of Edward the Confessor, and being royal property a wooden church may have existed there in Alfred's time, and almost certainly there would have been one in the days of Æthelstan, for he enacted that if a ceorl (freeman) thrived so as to have five hides of land, a church, a kitchen, a bell tower, and a seat in the Witenagemot, he became a thegan (nobleman); and this was a great incentive to church-building. In the Saxon charters collected by Kemble, three Worths are mentioned—Wrth, in Lincolnshire; Wyrth, in Oxfordshire; and Weorthig, in Buckinghamshire; but there is no allusion to Worth in Sussex. Worth, with its variant spellings, is defined by Bosworth as a close, field, farm, manor, estate, &c. In Sussex the word also occurs in Worthing, Petworth, Densworth, Aldsworth, and Fittleworth.

As late as 1870 Lower wrote, "Worth is not mentioned in Domesday," repeating the words that had been used by Horsfield in 1835. Worth, however, joined the Surrey border, and at the Norman survey it was included in the Hundred of Churchefelle, now Reigate; and it appeared as Orde, the unfamiliar W being omitted by the Norman scribes. As translated by Mr. L. F. Salzmann, B.A., the entry runs:—"Siward holds of Richard, Orde. Oswol held it of King Edward. Then and now it is assessed for half a hide. There is one villein with half a plough. In the time of King Edward it was worth thirty shillings, and afterwards two shillings, now twenty shillings." There is no mention of a church, but in this particular Worth did not stand alone, for in the Survey of Sussex there is no entry of a

SAXON WINDOWS, WORTH CHURCH.

church at Selsey, which a few years before had been the cathedral, of St. Dunstan's Church at Mayfield; nor of the nine churches at Lewes, which, from charters of the time, are known to have then existed. So may we not believe that there was a church at Worth? And as the ablest judges place its date about 1050, I venture to suggest that the rich Saxon Oswol was its builder.

The Richard of the Survey was Richard FitzGilbert, who owned 176 manors, and building the castle at Tonebrige was generally styled Richarde de Tonbridge; and Mr. J. A. Archer regards him as the first Earl of Clare. His property, including, as we may suppose, Worth, passed to his son Gilbert, who, dying in 1115, was succeeded by his son Richard, whom King Stephen had created Earl of Hertford. His son Gilbert died in 1152, and his brother Roger succeeded to the titles and estates, and, dying in 1173, left the property to his son Richard. This Earl Richard had married Amicia, one of the daughters and co-heiresses of William, Earl of Gloucester—also a De Clare—and her sister Isabel was the wife of King John; and we may surmise it was by a friendly exchange of manors that the king acquired possession of Worth.

The Rev. Arthur Bridge, in a very interesting book on his church, quotes from the Burrell collections of an expenditure for timber for Worth Church during the minority of a De

Digitized by Google

Warenne, owner of the manor, assumed to be the John, Earl of Warenne, who in 1255 "came in the Octave of St. Martin, at Cycester, and said that in Worth"—and elsewhere—"he had parks, and asked if the king (Henry III.) had any claim" to them, "to which William de Gyselingham said that, for the present, he claimed nothing therein." Dugdale records that in 1278 (Edward I.) John de Warenne, Earl of Surrey, was questioned before the justices itinerant by what right he claimed free warren in Worth and other places. He replied that his ancestors had lost their lands in France through adhering to King John, who had compensated them with lands in England; and he also claimed free warren in the king's manors by right of his name, and his claim was allowed. The rector further says that Worth Church is mentioned in the taxation of Pope Nicholas about 1291. From Horsfield we learn that John, the seventh and last earl, died seized of the Barony of Lewes, including Worth, in 1347. A year or two later his daughter married Thomas Fitz-Alan, Earl of Arundel, and on the death of the fifth earl in 1415 Worth and the other lands passed to the Nevills, Earls of Abergavenny. A survey of Worth was taken by Richard Benton, measurer, October 15, 1583, when the whole forest comprised 5,134 acres 2 roods. Mr. Stebbing shows that as late as 1808 Worth was known as Word or Worde. In Capper's Topographical Dictionary of 1839 the present spelling is given. Worth then consisted of 264 houses and had 1,725 inhabitants, and he gave the value of the rectory as 13*l.* 3*s.* 4*d.*, as quoted by Horsfield from the king's books; and Capper mentions places simply known as Worth in Devonshire, Kent, and Cheshire.

WOODEN HOUSE AND LYCH GATE, WORTH.

Although the original dedication of the church is not known, it is believed to have been in honour of St. Nicholas, who was made Bishop of Myra by Constantine the Great, and took a prominent part in the Council of Nicæa in 325. No better description of the church can be given than in the words of Mr. Philip M. Johnston, F.R.I.B.A., who says the apsidal and cruciform plan, the chancel arch of bold proportions and wide span, the massive transeptal arches, the lofty north and south doorways, the windows in pairs with mid-wall balusters, the external string-course and the pilaster strips are the most noteworthy features of this remarkable church. Mr. W. P. D. Stebbing, who has written the latest and fullest description of Worth, states that the church is built of the local Tilgate Forest sandstone, and adduces evidence to prove that it was erected about 1050, and that the ground plan has never been altered. The position of the Saxon windows—with the exception of one in Oxford Cathedral—he regards as unique. Various opinions have been offered as to why windows were placed so high, but I think it may have been to allow space for mural paintings, which were a factor in the education of the people; and we know the custom survived in the construction of royal and other banqueting halls, where tapestry took the place of wall-paintings. Of mural painting only a little thirteenth century ornamentation remains around a window on the south side. The arched recess in the south transept Mr. Stebbing regards as coeval with the church, and the font he considers is the original one and ornamented in the thirteenth century. The font, curiously, is stated to consist of two basins, the one supporting the other; the panel on the south side is peculiar, having two tiers of pointed quatrefoils, three in each row. In the window of the north transept the arms of a De Warren have been preserved, and it would be interesting if we could regard it as having been made at the early glass works at Chiddingfold. The oak pulpit is dated 1557 and is beautifully carved with figures of the Saviour and Evangelists. Mr. H. S. Vaughan states that it came from Worth, in Germany, a special reason why it was purchased by the Rev. G. C. Bethune in 1841. The inscription is of great interest, as it shows how the language of the Plats—the ancient English—had altered in its native country. As literally translated by the rector it runs:—"Who me loves the same will my word hold, and my father will him love, and we will to him come and a dwelling with him make." (St. John xiv. 23.) The sixteenth century altar rails of foreign workmanship are carved with scriptural and other subjects; the oak minstrels' gallery is inscribed, "This gallerie is the gift of Anthony Lynton, late Rector of this parish, who deceased the xv. day of June, Anno Domini, 1640"; and Horsfield says his name appears on one of the windows of the rectory with the date 1592. Some of the old pew-ends form a panelling in the south transept; near by is an old raised-topped chest with three locks, and two beautiful candelabra of twelve lights adorn the church, upon which about forty years ago the sum of 3,831*l.* was expended. Memorials remain to the families of Gale, Smith, and Blunt, of Crabbet, and to members of the Bysshe, Shelley, and Bethune families. The register dates from 1600, and the old lych-gate gives an added charm to one of the most interesting parish churches in the kingdom.

The place names denoting Saxon settlements can scarcely be numbered, Kemble deriving 1,329 from tribes and families alone. The Saxons gave us the hondred and the scira (shire); from their folk-moots arose trial by jury, and the High Courts of Parliament are the development of their witenagemots. Many noble families point with pride to the Roll of Battle Abbey where the names of their ancestors are inscribed, but a few trace their lineage from the Saxons; among them are the Earl of Durham, the Earl of Scarborough, descended from Liulph in the time of Æthelred II.; and the Marquess of Abergavenny, whose ancestor, Dolphin, son of Uchtred, had a grant of Raby Castle, which Canute had built; and by the marriage of King Alfred's daughter Ælfthryth with Baldwin, the second Count of Flanders, Edward VII. is descended from the great Saxon kings.

In addition to the writers quoted, I am indebted to several others, including William Howitt, Ernest A. Baker, M.A., H. M. Scarth, M.A., Grant Allen, B.A., Romesh Chandra Dutt, C.I.E., J. A. Blackwell, and Wentworth Huyshe; and to Mr. J. Downes I tender my thanks for considerable assistance given me.

THE HOUSE SANITARY.

WHO should be responsible for the healthy home, its drainage, its ventilation, its sanitary condition at large? "The individual," says Mr. Mark H. Judge, whose article in the *Westminster Review* upon "Communal and Individual Responsibility as Regards Health Conditions" has just been reprinted in pamphlet form. "The State," says Mr. B. G. Bannington in the current number of the same Review under the title of "The Rule of Liberty and Health Administration." Says Mr. Judge, "We expend our means on purposes which are outside the proper functions of Government"; he quotes Ibsen's "Enemy of the People" with its bitter satire upon municipalism, and declares that the mass of modern legislation, while pretending to make our public authorities responsible for the condition of every house drain, succeeds in weakening the feeling of individual responsibility and "fails to insist on anything with consistency. Public authorities often do as much to hinder sanitary improvement as they do to advance it."

Mr. Bannington, *per contra*, literally attacks the whole principle of liberty; draws the opposite moral from Ibsen's play—that if the community is blind to danger it "should be led by others more enlightened and experienced in the public needs. The public health is a public charge." . . . Against "malign factors war must now be waged in the interests of the public health. This is a task for the State and not for the individual." It would hardly be possible for issue to be joined more clearly.

The public authorities, says Mr. Judge, too often neglect the public sewers, allow dwelling houses to be directly connected with them, and then, to guard the inhabitants against the resulting evils, "the private dwelling is intruded upon by a public officer." The owner or occupier

Digitized by Google

should be held responsible for the sanitary condition of his house, and "it is no more the business of the local authority to provide a sanitary surveyor to design the sanitary arrangements of a house than it is to provide an architect to plan the building." If the communal plan of life be adopted "why not, when in legal difficulties, an application to the local authority's solicitor?"

Increased individual responsibility rather than increased interference by public authorities is what Mr. Judge recommends as the road to improvement in matters sanitary, with the following simple rules to be enforced.

All public sewers or common drains to be public property and in charge of the sanitary authority; between every house and the sewer an air-chamber and disconnecting trap where it can be readily inspected; the drain between the trap and sewer to be public property and in charge of the sanitary authority; flushing and ventilation to be the duty of the authority; no house drain to be connected to any public sewer until after a duly signed certificate as to the sanitary condition of the house has been deposited with the authority; the owner or occupier to be responsible for the disconnecting trap, flushing, and ventilation of the drain on the house side of this trap, "and for keeping the sanitary arrangements of the house in such a condition that no nuisance shall result."

Underlying these details are larger questions vitally affecting the architecture, the health, and the social condition of our great cities. Does the State exist for the individual or the individual for the State? Shall the individual virtually lose his identity and become a municipal unit, allow the sense of personal responsibility to decay and look to the State for everything? Unquestionably the State has advanced and extended its claims of late years to an extraordinary extent, and nowhere more insistently than in building and, above all, sanitary matters. How far shall the system be carried? Can it be extended beyond the point it has at present reached with advantage to the community? These are questions for the public, deeply affecting the future of our great cities. There is another question also which is raised in this connection, a question which greatly affects the architect. Up to a comparatively recent period in England the law confined itself to telling a man what he might not do; the tendency at present is towards laws which tell him what he must and shall do. The subject is too large to be pursued here, but no law can be considered an improvement which weakens the personal responsibility of the citizen for the home in which he lives.

THE OUTLOOK FOR TIMBER SUPPLIES.*

MUCH attention has recently been given to this subject, and the general opinion is that prospects are not reassuring. Britain paid twenty-seven millions sterling for wood on the average of the five years 1904-8, as compared with eighteen millions 1889-93, an increase of 50 per cent. Even Germany, with nearly twelve times the area of forest that we possess, pays annually some twelve millions sterling for imported timber. Although the U.S.A. exports wood and wood-products to the value of twenty millions sterling per annum, she has to pay as much for imports. In Europe, Sweden and Russia are the chief timber-exporting countries, and it seems unlikely that these countries can maintain supplies. Sweden, it is officially stated, is over-cutting her forests to the extent of more than 100 million cubic feet yearly, while Russia is already reducing her exports. In various official publications the Department of Agriculture of the United States has drawn attention to the prodigal method in which her forests are exploited, and has pointed out that in a few years she will not even have timber enough for her own supplies.

There are only two regions of the world that may contain sufficient areas of virgin coniferous forest appreciably to affect the situation. The one is Canada, which in the north-west, and also north and east of Lake Superior, contains large tracts of untouched forest. The growing stock of large stretches of country west of the Rocky Mountains is undoubtedly large, and is now having an appreciable effect on market supplies. The timber that may become available along the line of the new Grand Trunk Railway is much more problematical. The area is vast, but the density of the stock is said to be poor, and the individual trees and rate of growth are small. The other region of the world that contains large stretches of virgin forest is Siberia. Although the density of Siberian forests cannot compare with well-stocked land in Europe or America, her areas are so vast that it cannot be doubted that this country possesses enormous stores of wood. But the difficulty in her case is to get them out. The navigation of the Arctic Ocean is too dangerous to be undertaken for timber cargoes at anything like present prices. Nor would it be profitable to move timber along the Trans-Siberian Railway. The only way to get part of Siberia's timber to market is to float or ship it down the rivers, such as the Amur, that debouch into the Pacific. This is already being done to some extent, and in time such supplies will go some way towards satisfying the demands of China, Japan and Australia.

The growing scarcity of supplies of timber is clearly reflected in the prices on the world's markets. Thus in Britain the largest class of timber has risen in value 28 per cent. in the last fifteen years. Concurrently with the rise in price there has been a marked falling off in quality, so that the real rise in price has been much more than the figures indicate. The United States Department of Agriculture recently issued a table which showed the prices ruling for various classes of timber in various American markets during the past twenty-two years. Of thirty-two brands of timber, nine had risen over 100 per cent., and only two had risen less than 25 per cent. Effective relief through the agency of timber substitutes seems improbable. Concrete and iron are, of course, used to some extent in place of wood, and there is a talk of sugar-cane stalks becoming important in paper-making. But with it all, the demands for wood continue to grow, and although economic prophecies have often proved to be wrong, it seems impossible to escape the conclusion that the future of the world's timber supplies is distinctly disconcerting. It would therefore appear to be in the interests of every country to take energetic steps to prevent the wasteful destruction of timber by forest fires, to see that denuded areas are at once regenerated, and to undertake the planting of all land that can be better utilised under silviculture than through the agency of pastoral occupation.

* From a paper by Professor Somerville, read before the British Association for the Advancement of Science at Winnipeg.

THE AGE OF STONE CIRCLES.*

IN planning the arrangements for further excavations at Avebury Stone Circle, in continuance of the work done last year, the committee were of opinion that the most satisfactory results were likely to be obtained from renewed examination of the silting in the fosse, particularly the lowest layers occupying the original bottom of the huge trench. It was also considered desirable, as a minor operation, to explore the ground at the base of one or more of the prostrate stones of the circle, with a view to examining the original sockets in which the stones stood when erect. Instructions were accordingly given to Mr. H. Gray, whose services were again secured, to concentrate attention upon these two main objects. The details of the excavations, and the results obtained, are given in the appended report by Mr. Gray, and the committee have every reason to feel satisfied with the manner in which the work has been carried out and the care with which the exact position of all "finds" has been determined and recorded.

To expose even a small area of the original bottom of the fosse is of necessity a work involving great labour, owing to the enormous amount of silting which must be moved, and in view of the smallness of the available grant it was necessary to invite subscriptions from other sources. The response made to the appeal for funds has been gratifying, substantial assistance having been forthcoming from societies and from private individuals. A list of donations appears in the accounts for the year, and the committee take this opportunity for thanking those who have contributed so generously; without their assistance, work on any substantial scale would have been impossible. The Rev. E. H. Goddard very kindly undertook to collect subscriptions from members of the Wilts Archæological Society. The thanks of the committee are also due to Lord Avebury and to Captain Jenner for permission to conduct excavations on their property; also to the Rev. T. G. Ward, vicar of Avebury, for assistance in securing labourers. The committee wish also

* Abstract from report of the committee, consisting of Dr. C. H Read (chairman), Mr. H. Balfour (secretary), Lord Avebury, Professor W. Ridgeway, Dr. J. G. Garson, Dr. A. J. Evans, Dr. R. Munro, Professor Boyd Dawkins, and Mr. A. L. Lewis, appointed to conduct explorations with the object of ascertaining the age of stone circles. Drawn up by the Secretary.

Digitized by Google

to acknowledge gratefully the courtesy with which the Somersetshire Archæological Society made it possible for Mr. Gray to have leave of absence from Taunton during the period of the excavations.

The main result achieved from the deep cuttings in the fosse is a confirmation of the opinion arrived at last year as to the probable date of the monument. Additional positive evidence has been obtained from the objects discovered in the lowest layers of silting and on the original bottom of the ditch. These in all cases are objects such as are characteristic of the Neolithic period, and although it would be hazardous to state definitely that they must be of Neolithic date and cannot belong to the Bronze Age, the negative evidence afforded by a total absence of copper or bronze and of objects which are certainly of Bronze Age affords powerful confirmation of the probability of the earlier date being the right one. A transverse section of the fosse close to the modern road was expected to reveal the sloping sides of the causeway presumed to exist, connecting Kennet Avenue with the interior of the monument, since at first sight it seemed likely that the road would have followed the line of the causeway. No trace of the latter, however, appeared in this section, and as it was of considerable interest to ascertain whether or not such a causeway had existed, exploring trenches were cut on the opposite side of the road, and the causeway was discovered to the east of the present roadway. This locating of the original line of approach to the interior of the huge circle is a most interesting result of this year's excavations.

Sectional and other plans of all the parts excavated have been prepared with very great care, and a large number of excellent photographs are now available.

The grant from the Association having been expended together with most of the money raised by subscriptions, it becomes necessary to apply for a fresh grant to carry on the work. The committee ask to be reappointed and apply for a grant of 75*l.*, and also for leave to invite subscriptions in order to make up a sum sufficient for carrying out effective exploration. The huge scale of the earthwork renders its investigation comparatively costly and laborious, as the mass of silting in the fosse is very great. It is very desirable to continue the work next spring, in order that making good the already disturbed ground and conducting fresh exploration may proceed together. The advantage, moreover, of being able to secure men who have already worked under Mr. Gray's supervision is obvious, and some of those employed in this year's excavations would no doubt be available next year; continuity in their employment would undoubtedly save much trouble in training them to the work. The thorough investigation of this splendid monument is of the greatest importance, and it is to be hoped that adequate funds may be available.

THE AVEBURY EXCAVATIONS, 1909. By H. ST. GEORGE GRAY.

I. *Introductory Remarks.*

In the report of the excavations, 1908 (*Brit. Assoc. Reports*, 1908, pp. 401-13), an epitome was given of the existing archæological literature on Avebury, having reference to its stone circles, surrounding earthworks, and ancient remains in the immediate neighbourhood; and a summary representation of the opinions and observations of several authorities on Avebury, including Aubrey, Stukeley, Hoare, Crocker, W. C. Lukis, Fergusson, and the Revs. A. C. Smith and Bryan King, was also placed on brief record. In another section a condensed account was given dealing with previous and less extensive excavations which had been conducted in various parts of "the Temple" between 1865 and 1894; none of these, however, produced any definite evidence of date, for the reason, mainly, that scientific method in archæological fieldwork had not then attained to the standard aimed at in the present century.

Having dealt with Avebury under these headings in the previous report, the present account will be almost confined to the excavations conducted from Monday, April 26, to Monday, May 17, the filling-in, completed this year, continuing till May 20.

A maximum number of sixteen men was employed this season, eleven being engaged in 1908. The weather was highly favourable during the three weeks, only four hours being lost owing to rain. Last year we were much hindered by falls of silting from the almost vertical sides cut as the digging penetrated into the lower levels of the great fosse. But, having grown wiser, we left a considerable batter to the faces of the silting this season, at the expense, however, of uncovering a relatively shorter length of bottom of the fosse.

A number of sectional diagrams were made as the work proceeded, in which the various soils were indicated and the exact position of every object of importance found during the exploration was projected into these sections, notes being made relating to each numbered "find." Eleven sectional drawings and plans were made, and a scale map of the whole area excavated in 1908 and 1909. An average section of the southern fosse having been given in the Report of 1908, it will be unnecessary to publish another on the present occasion, the previous one being fairly representative of the other sections made for the sake of careful record and precision.

Twenty-two satisfactory photographs (half-plate) were taken during the season and sixteen last year, some showing the progress in the excavations from time to time as new features presented themselves, others being interesting views of various parts of "the Temple" taken under favourable conditions of light.

The excavations were visited by some of the members of the British Association Stone Circles Committee, by Fellows of the Society of Antiquaries, and members of the Wilts Archæological Society and Marlborough College Natural History Society.

Most of the excavations have now been filled in, but Cutting II. through the fosse has been left open for the inspection of visitors during the summer.

II. *Geological Note.*

Avebury is on the Middle Chalk, but Mr. A. J. Jukes-Browne, F.G.S., informs us that the area has not yet been accurately mapped, and it is uncertain whether the site stands on the *Terebratulina gracilis* zone or that of *Rhynchonella Cuvieri*. Of the fossils from the Avebury fosse, 1909, all are *Inoceramus mytiloides* except two, which are *Rhyn. Cuvieri*. Mr. Browne also reports that "the evident abundance of *Inoc. mytiloides* is greatly in favour of the zone of *Rhyn. Cuvieri*; they are seldom abundant in that of *Terebratulina*, which always consists of fairly soft white chalk, while that of *Rhyn. Cuvieri* is harder, more nodular, and often yellowish."

Iron pyrites were commonly found in the fosse cuttings.

III. *Excavations into the Fosse.*

(*a*) *Cutting I.*—Rather more than three-quarters of the silting from this cutting was re-excavated last year. It was 24 feet long, all the upper deposits down to the top of the Roman stratum being removed in 1908, and a length of 17 feet cleared at the bottom (*Report*, 1908, pp. 408-10). It remained, therefore, to uncover 7 feet on the E. margin this year. Roman pottery was found at depths of 5.7 and 6 feet respectively, and a human clavicle, depth 8.5 feet. The mixed silting was reached at a depth along the E. margin of 9.1 feet (the depth on the W. margin being 8.7 feet). After having penetrated the chalk rubble to a depth of 12 feet from the surface a large fall of several tons of material from the E. face had to be contended with, and, although the labour entailed thereby was considerable, the final results were satisfactory. Eventually the bottom along this margin was reached at a depth of 17.8 feet from the surface of the silting, and we were rewarded by finding, in all cases on the floor, four antler picks. Cutting I. produced in all (1908-9) parts of ten picks of red-deer antler and a shovel of shoulder-blade bone—implements which had been used in the original excavation of this huge fosse.

But the most interesting discovery on the floor was the chipped flint knife, a piece of flint full of sponge-spicules which appears to have been slightly scorched but never burned red-hot, and a piece of charcoal. The knife is not only of characteristic Neolithic type, but most probably of Neolithic date. It is of a kind frequently found on the site of an ancient factory of flint implements on Windmill Hill, about a mile to the north-west of Avebury.

(*b*) *Cutting II.*—This cutting was pegged out last year also to a length of 24 feet, the W. margin being 69 feet to the E. of the W. margin of Cutting I. Being nearer the road on higher ground, it was obvious there would be a greater amount of surface silting to remove than in Cutting I. Last year a length of 9.5 feet was dug to a depth of 5.5 feet, and in the re-excavated material were found a number of shards of Norman and mediæval pottery (*Report*, 1908, p. 410). It was at this point that we continued operations this year. The surface silting was found to extend to an average depth of 5.8 feet in the middle. Nothing worthy of particular record was found in it; but a number of shards of mediæval date and even later, together with an Irish halfpenny of George III. and a seventeenth-century tobacco-pipe of clay, bearing the name of "Thomas Hunt" on the heel, were collected from depths varying from 1 to 3 feet. Another tray of pottery of similar character was preserved from depths of from 2 to 4.5 feet, and other mediæval fragments were found along the

Digitized by Google

E. margin of the cutting at depths between 4.5 and 5.8 feet. The upper deposits had probably been disturbed, and further inquiries led me to believe that the surface of this part of the fosse had been cultivated up to the third quarter of last century.

The next deposit—mixed silting, consisting of mould with a larger proportion of small pieces of chalk—extended to an average depth of 10.3 feet in the middle. The lower 2 feet of this silting was found to be of a finer kind with a smaller admixture of chalk.

Eight lots of Roman or Romano-British pottery were found in the mixed silting at depths varying from 5 feet to 8 feet. One piece was picked up at a depth of 8.5 feet, but it may have tumbled down during the digging. Several pieces of pottery of bronze age type were also found in the mixed silting at depths between 8.5 and 9.5 feet and above the pure chalk rubble. This pottery was of the soft smooth hand-made cinerary-urn type containing few grains of quartz; one piece has a typical cordon or encircling ridge. This deposit also produced human remains in two places to a maximum depth of 9 feet. Flint flakes were also found, and four objects of flint, including a good specimen of an oval scraper.

Between the mixed silting and the chalk rubble in the middle part of the silting, tapering in both directions, a seam of crystallised chalk, almost impenetrable to the pick-axe (indeed, it broke two points), was reached; it occurred at the same level in all the cuttings made. Carbonate of lime had consolidated the chalk and rendered it as solid as the hardest concrete to a thickness of 1 foot in places. The workmen considered it to be the bed of an ancient watercourse. In any case, there must have been a considerable soakage of water to deposit carbonate of lime in such quantity.

Owing to the curvature of the stratum in the silting, the chalk rubble on the sides of the fosse extended almost to the top; in the middle it was reached at a depth averaging 10 feet. From here to the bottom, as elsewhere, silted chalk rubble only had to be removed, with thin seams of dark mould caused by the occasional falls of turf. A piece of early British pottery was dug up at a depth of 8.7 feet near the southern margin of the fosse. No other pottery was discovered, but four pieces of worked flint were found at depths between 6.5 feet and 9.5 feet (none in the middle depths of the fosse).

The greater parts of two antler picks were found in deep positions, as described below. Six of these picks were recovered during the season. Since the Avebury Report, 1908, was written, explorations at Maumbury Rings, Dorchester (which I had the charge of), revealed a Neolithic shaft, 30 feet deep, in the solid chalk below the floor of the Roman arena, in which no less than nine antler picks were found, some being in good preservation, two having the smoothed grips like some of the examples from Avebury and the Grime's Graves. The Dorset County Museum contains parts of antler picks also from Jordan Hill, Fordington, Hambledon Hill, &c.

Close to the bottom of Cutting I. last year we found a fragmentary *scapula* in a shattered condition, its position, &c. (*Report*, 1908. p. 410), suggesting its use as a shovel of the character of those found in the Neolithic flint-workings at Cissbury, specimens from which may be seen in the British Museum and the Pitt-Rivers Museum at Oxford. A number of worked *scapulæ*, one being finely ornamented, were found in the Meare Lake Village. In the 1909 excavations at Avebury three well-defined specimens of these shovels were found in Cutting II. fosse, two shoulder-blades of ox (*Bos longifrons*) being found on the floor of the fosse at depths of 18.5 and 18.8 feet respectively; the other was a *scapula* probably of pig (*Sus scrofa*), found at a depth of 14.3 feet in the chalk rubble, having perhaps slipped down from the vallum before it became turf-clad. The two shovels of *scapulæ* of ox measure 13¾ inches and 12½ inches in length. In two cases the large anterior spine has been cut away, or partly removed, and from this fact and the worn appearance of the three specimens, together with the great scarcity of other animal remains, except the antler picks at such a great depth, we think it more than probable that they were used as shovels in the original excavation and clearing of the fosse.

The bottom of the fosse, Cutting II., was just as smooth as in Cutting I., but it narrowed slightly. In Cutting I. the width at the bottom varied from 16 to 17.3 feet. In the W. half of Cutting II. it varied from 11.8 to 17 feet; in the E. half it averaged 14.3 feet. The walls of the fosse in the lower parts (Cutting II.) became steeper and were very uneven, there being considerable projections of hard chalk left apparently for no particular purpose. We experienced no fall from the E. face of the silting, it being sloped as the excavation proceeded to the extent of 4½ feet out of the vertical. The bottom was found to rise towards the east slightly, and along the E. margin a ridge (height about 0.9 foot) of solid chalk crossed the fosse as shown in one of the sectional diagrams; in the middle of the ridge was a slight hollow. We could not, of course, ascertain whether this sudden slight rise continued in an easterly direction.

The depth of Cutting II. from the surface of the silting on the west was 18.8 feet; on the east 20.5 feet; the difference being accounted for from the fact that the surface rises considerably towards the road.

(*d*) *Cutting III.*—The E. margin of Cutting III. was only 6 feet W. of the middle of the western hedge bounding the modern road into Avebury from the south. A length of 14 feet of fosse was marked off for examination. It was close to the gate of the high road, and was dug to ascertain if the fosse rounded off to form a solid entrance-causeway.

Both Aubrey and Stukeley apparently show the position of the Kennet Avenue entrance into Avebury as being exactly on the site of the present road, and this fact rather led one to suppose that the fosse of the W. side of the solid entrance-causeway must have terminated in about the position of the present western hedge. But our excavation into the fosse of Cutting III. proved that their plans are incorrect and misleading.

In 1908 (*Report*, p. 410) we made several trial holes to ascertain the direction towards the east taken by the upper margins of the walls of the fosse exposed in Cutting II. Holes were made along both margins, and in all those nearest to Cutting II. the solid chalk upper border of the fosse-wall was revealed; but instead of the fosse narrowing it widened as it approached the hedge and road.

This year before re-excavating a part of Cutting III. we dug a trench about 32 feet long and 5 feet wide, connecting the northern face of Cutting II. with the northern face of Cutting III., and clearly exposed the upper walls of the fosse. On the top of the solid chalk "wall" in the N.N.E. corner of Cutting II. a slight platform was observed. It was found on excavation to continue a little towards the north, but judging (1) from the apparent hollows in the turf-clad inner bank for some little distance round, and (2) the fact that modern shards were found down to the solid chalk, it appeared evident that a recent excavation had been made here, perhaps for chalk, as in the much larger mutilation in the vallum opposite on the south.

Having re-excavated Cutting III. to a considerable depth we felt bound to complete the northern portion of it to the bottom, which the fine weather permitted us to do, but, as we shall see presently, we proved the existence and position of the ancient entrance-way on the E. side of the modern road.

It soon became clear in digging Cutting III. that the fosse approaching the causeway from the west not only maintained its great depth, but expanded considerably towards the point where it rounded off to form the causeway under what is now the high road into Avebury.

The top margin of the fosse in Cutting III. proved to be 52 feet wide, and the whole of the filling to a depth of 5 feet was removed. This produced no object of importance and consisted entirely of silt from the hedge and road and a loamy tenacious material said by the local people to have been brought to this spot from the site of the "New Bridge" across the Kennet stream on the Devizes road, quarter of a mile S.W. of our diggings, when it was built. It entailed much manual work to remove this "dumped" material, but afterwards we came upon the same ancient deposits as occurred in Cuttings I. and II., making "finds" of pottery and a well-worn flint scraper.

At length we reached the bottom at a depth of 23 feet from the surface, but nothing was found in the lowest depths but a *scapula* of sheep at 18 feet; and no remains actually on the smooth floor of the fosse, which was exposed for a width of 8 feet and a length averaging 3.8 feet. In no part of the excavations could one realise better the immensity of the great fosse and the labour its construction must have entailed when metals were unknown in Britain. This inner slope of Cutting III. was the finest example of cut chalk exposed in any part of the excavations; and the uniformity of the slope and the absence of projections seemed to indicate that the fosse was originally excavated with greater care near the entrance-causeway than elsewhere. The average inclination of the fosse wall was at an angle of 63½°, and covered a length of 26.5 feet on the slope; but the steepness of the profile in the lowest 6 feet was remarkable, being at an angle of 81°, the chalk resting in immense solid blocks in its natural condition. No ancient tool-marks were observable on the walls of the fosse, near the bottom or elsewhere.

(*To be concluded.*)

THE BEHAVIOUR OF DUCTILE MATERIAL UNDER TORSIONAL STRAIN.

A PAPER was read by C. E. Larard, Assoc.M.Inst.C.E., M.I.Mech.E., before the British Association for the Advancement of Science at Winnipeg. The researches reported in this paper were carried out on different diameters of wrought iron, mild steel, and nickel steel, varying from half an inch to three inches. Some of the results obtained may be summarised as follows:—

1. For ductile material there is no well-marked yield-point similar to that obtained for tension tests.

2. When the maximum torque is reached failure takes place by the specimen commencing first to shear round the periphery over a small annulus of material, this shear gradually extending inwards from annulus to annulus at a reducing torque until the final fracture of a more or less central core in tension, accompanied by a loud report. This failure in two stages is brought about by the irregularity in the form of the fracture during shearing, whereby a wedging action is set up over the large annulus surrounding the core, thus producing compression across the annulus and tension in the core. The diameter of the tension core is roughly proportional to the diameter of the specimen. For a homogeneous material the relationship between torque and local twist is given by a rectangular hyperbolic curve.

3. The torque twist curve throughout the entire test, from the elastic limit to the breaking torque, follows a compound interest law, and an expression has been obtained by means of which the work to destroy the specimen can be calculated; and the result has been confirmed by integrating by means of a planimeter the autographic torque-twist diagram.

4. For a homogeneous material the work done is proportional to the volume, whatever the diameters and lengths of the specimens.

5. For a homogeneous material the torque at fracture is directly proportional to the cube of the diameter of the specimen, when the diameter varies.

6. (*a*) Principal transverse sections by planes at right-angles to the axis before twisting remain plane during twisting. (*b*) The unitary structural parts of the material at different radii in a given section undergo during torsion the same angular displacement. (*c*) Straight generating lines on the cylindrical surfaces before torsion are twisted up into helical lines, defining lines of helical shear. (*d*) Any sector of a homogeneous cylinder is twisted up so as to form a sectorial screw. (*e*) The shear stress at any radius and also along the helical lines may be calculated from the usual shaft formula. (*f*) For a homogeneous material the angle of the helical lines of shear tends to have a constant value for any diameter of a specimen; consequently simple mathematical relationships between the variables of the experiments may be obtained.

7. A specimen under torsion undergoes changes in its dimensions, there being an axial elongation following the compound interest law and a small reduction in diameter. Further, it would appear that when work is done in producing plastic deformation with corresponding increase in elastic resilience the volume is slightly increased.

8. The elastic limit and the elastic resilience of material may be raised above the primary limit, which is purely an artificial one produced by manufacturing operations, by (*a*) overstraining, with full recovery of elasticity to a higher limit by heat treatment at low temperatures. (*b*) By indefinitely long rest after overstraining. (*c*) By continuous stressing of material at a fairly constant load above the primary elastic limit. (*d*) In manufacturers' works by scientific straining with subsequent heat treatment. (*e*) Considering the forms of iron and steel, by the addition of a small percentage of some other element. Any one of these methods increases the ratio of elastic limit to maximum load, and the ratio of elastic resilience to the total work which has to be done on the specimen to destroy it. That is to say, the useful "play" energy for practical working stresses may be increased in some cases with resulting economy of material.

9. A comparison of the results of the tests on wrought iron and steel shows the great superiority of steel as compared with wrought iron for shafting.

10. The author, in conclusion, drafted a specification for torsion tests based on the results of the experiments given.

The Date for sending in designs for a college at Hull for the training of teachers for elementary schools has been extended from October 11 to October 18.

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *American Architect* has an article on "Fireproof Houses" by Mr. Frederick Squires, but these houses are really only less combustible than the ordinary "frame house," which has long been the normal type for the smaller suburban house or country cottage. The construction advocated is terra-cotta tile with a minimum of concrete. The illustrations comprise a number of small houses designed by Messrs. Squires & Wynkoop, which are examples of "fireproof houses," but although sometimes suggestive are not very remarkable.

La Construction Moderne illustrates the designs that have this year obtained the first and second awards in the students' competition for the Grand Prix de Rome, the blue riband of the French architectural student. An exhibited drawing from the Salon is also reproduced, the subject being a purely academic one—a triumphal bridge designed by M. Maurice Durand. A series of articles is commenced on how to draw perspectives with a home-made trammel, avoiding vanishing points and other troublesome features of the routine method.

Deutsche Bauzeitung has an interesting article, with illustrations, on the Mediæval town of Cordes, in Southern France. The restored Diana Well in Hildesheim is also illustrated. There is an article descriptive and explanatory of the new police regulations for the planning and building of theatres in Berlin.

Dekorative Kunst gives us a description with illustrations of some modern German cemeteries, in which the inherent ghastliness of the wilderness of monuments in the older type is masked by extensive tree-planting. The most successful of these seems to be the Ohlsdorfer Cemetery at Hamburg. Another and more cheerful article describes and illustrates the interior decoration and fittings of the Bodensee steamship *Friedrichshafen*. A pleasant change from the normal flat residence is a one-family house in Hanover, designed by Karl Hubert Ross, which is full of piquant internal effects.

Moderne Bauformen, *à propos* of the Düsseldorf exhibition of Christian art, gives us a purview of modern ecclesiastical architecture, of which the examples are not confined to German lands, but include some of the work of Henry Wilson, Nicholson & Corlette, Walter Crane, and Bentley & Marshall, the last being of recently added fittings for the Westminster Cathedral.

The *Scientific American* gives a short account, with some striking illustrations, of the excavations at Delos carried on since 1903 by the French School of Athens.

Construction has an interesting illustrated article on "Bonds, Mortar, Joints, Colours and Patterns" of brickwork which is eminently suggestive of the variety of texture that can be given to brick walling by thoughtful originality.

NOTABILIA.

THE *Art Journal* contains an original etching by E. Marsden Wilson, A.R.E., of Didcot Church, which is a charming presentment of a small but picturesque building. A. L. Baldry contributes another of his instructive articles on "The Treatment of Drapery in Sculpture," with fine illustrations from both ancient and modern work. An interesting article on "Coffers, Chests and Caskets," by Luther Hooper, deals with Egyptian, Greek and Roman examples, and is to be continued.

The *Journal of the Royal Society of Antiquaries of Ireland* has a "pioneer" paper on "Dublin Harpsichord and Pianoforte Makers of the Eighteenth Century," by W. H. Grattan Flood, Mus.D. The productions of the musical-instrument makers of Dublin in the eighteenth century are not only interesting from a musical point of view, but also from the artistic. The illustrations to J. S. Fleming's article, "Irish and Scottish Castles and Keeps Contrasted," bring out the picturesqueness common to both.

GENERAL.

Mr. Charles John Holmes, M.A., Slade Professor of Fine Arts at Oxford, has been appointed director of the National Portrait Gallery in the place of Mr. Lionel Cust, M.V.O., who has been obliged to retire for reasons of health. Mr. Holmes is forty-one years of age, and for the past five years has acted as editor of the *Burlington Magazine*. He is also an occasional exhibitor of landscape subjects.

A Water-Colour Drawing by Turner entitled "The Falls of the Clyde" has been presented to the municipal collection at Liverpool as a memorial of the long connection of Mr. R. D. Holt with the local arts committee. In consequence of the overcrowding of the Walker Art Gallery a sub-committee was appointed last week to consider in detail and to prepare a scheme for the enlargement of the gallery.

FORTHCOMING EVENTS.

Saturday, September 11.

Architectural Association: Camera and Sketching Club, Visit to Guildford and district.

Society of Architects: Sketching Party to Rochester.

Northern Architectural Association: Visit to the Romano-British city of Corstopitum.

Monday, September 13.

National Association of Master House Painters and Decorators Annual Meeting opens at Sheffield.

Tuesday, September 14.

National Association of Master House Painters and Decorators: Exhibition opens at Sheffield. Lecture by Sir W. B. Richmond, R.A., "House Decoration for the Masses."

Saturday, September 25.

Institution of County and Municipal Engineers: Eastern District Meeting at Lincoln.

Monday, September 27.

Architectural Association: School of Architecture, Winter Term begins.

COMPETITION DRAWINGS FOR NEW OFFICES, BERKSHIRE COUNTY COUNCIL.

THE competition for proposed new county offices and committee rooms, &c., for the Berkshire County Council has proved unusually attractive, no less than 177 sets of drawings having been submitted. It is difficult to account for this rush unless it be that proximity to London has induced many young architects in the metropolis to try for a job near home and to neglect a larger one at Burslem, where there were only twenty-three designs sent in, and several of these alternatives. True, one guinea only was asked for particulars instead of the two at Burslem, and the name of the assessor was announced beforehand.

A very large number of good designs have been submitted, and though there can be no doubt of the superiority of the design by Messrs. WARWICK & HALL, placed first, despite some obvious minor defects, the assessor must have had considerable difficulty in selecting the other two that he considered worthy of a premium, and in our opinion has not been entirely successful, although we are willing to grant that he would devote more time to the consideration of the eligible competitors than we are able to do. Still in a closely fought competition much depends in the making of the award on the method by which an assessor decides superiority, and the methods adopted by various assessors are not all alike. It is highly probable that had the competition been assessed by another architect, shall we say more experienced in the judging of competitions, the result might have been different as regards the second and third places.

Strictly speaking several of the competitors ought to have been disqualified for violating the instructions, the most frequent infringements being the use of tinted or toned paper for mounts and the colouring of the half-inch detail.

There may probably be some discussion as to whether the selected architects have not infringed the conditions by arranging their bicycle store, coal store and packing room so that access from without is only possible by the use of Messrs. SUTTON'S private road. The question on this point raised by competitors reads:—"38. Is space between building lines to be a joint private road?" and the answer was, "No, this land belongs to Messrs. SUTTON & SONS." Most of the competitors have understood this to mean that the County Council and its staff would not be allowed the use of Messrs. SUTTON'S private road, but although the Council have no right, it is quite possible that the courtesy and generosity with which Messrs. SUTTON have treated the County Council in respect of the site might be extended to the use of their private road by officials, though not by the public. Messrs. WARWICK & HALL have evidently staked their chance of success on this further courtesy, and apparently justifiably. Thus when this point is carefully considered we cannot see that the winners have really violated the instructions of the competition.

Messrs. WARWICK & HALL have a delightfully simple plan, with a central entrance and direct corridor 6 feet wide leading therefrom. At right angles to this from about the centre is a corridor on the ground floor that communicates with the Assize Court, and off it is the staircase with lift running the whole height of the building. This staircase hall is sufficiently well lighted from an internal area, although only 9 feet wide. This area lights besides the stair and corridor, lavatories and store-room, and on the first and second floor offices for building inspector and the County Treasurer's chief clerk, who will scarcely have more light than they want. On the ground floor Messrs. WARWICK & HALL have located the Clerk's Department, the general office being at the end of the central corridor at the rear of the site, so that the public on entering have its door immediately facing them. The Clerk of the Peace and the assistant solicitor have their rooms to the front with the second assistant and the waiting room adjoining. The rooms of this department at the rear of the building and in connection with the general office are:—The chief clerk, second general office, typewriting room and store room. Well arranged between the principals and the clerical section of the department is a committee room, its doorway directly facing the corridor leading from the Council entrance from the Assize Court. Thus a plan effective in its interior architectural effect and conveniently arranged is obtained.

On the first floor is the Education Secretary's Department, arranged on a similar principle to that adopted on the ground floor, with committee room centrally placed between the officials and clerical staff. Minor accommodation overflows from this department, which requires more superficial area than any other, on to other floors, spare room, sun printing, store and packing rooms. On the second floor are accommodated the Medical Officer's Department, County Treasurer's Department and the Land Steward's Department. On the third floor are placed the County Surveyor's Department and the caretaker's quarters. Messrs. WARWICK & HALL have not considered it necessary to give the caretaker access to his rooms other than by the main staircase and lift.

In their external treatment the authors of the winning design have wisely not attempted to follow in any way, except in a maintenance of the chief horizontal lines, the design of the Assize Courts, but have designed a building thoroughly in consonance with the atmosphere of old Reading. A very clever piece of design is the one-storey colonnaded portico, the plan of which is admirably effective, both externally and internally. One commendable point in which Messrs. WARWICK & HALL excel almost every other competitor is that they have not built the back part shabby, but have treated their south and west elevations quite as architecturally, if not quite so expensively, as their front to The Forbury. This is not only æsthetically correct but is a delicate compliment to Messrs. SUTTON, as if the

Digitized by Google

architects would say, "You have been very good to our clients and so we will give you something pretty to look at." Most of the other competitors show elevations that are absolutely brutal in their callous indifference to the outlook of Messrs. SUTTON and their customers.

Coming to the design awarded the second premium, that by Mr. E. J. SHREWSBURY, we cannot help thinking that this was selected by the assessor amongst the three from which the final choice was to be made by himself and two members of the Council as coadjutors, to enable him to present a strong case in favour of what is undoubtedly the best plan submitted in the competition. The governing idea of this plan is best seen on the first floor, where the centre of the site is occupied by a lavatory block on either side of which is a small area 10 feet by 14 feet. The staircase flanks one of these, and around this group is a continuous corridor 5 feet wide, and surrounding this are the offices. The two small areas mentioned are not considered sufficient by the author, so he has a third 9 feet by 15 feet on second floor, and 9 feet by 7 feet on the ground floor. The main entrance is in the centre of the principal façade and opens immediately upon the principal staircase and lift, and from this on the several floors access is obtained. Thus the directness of the first premiated design is lacking. The external architectural treatment of this design is confined to the front elevation, and though good in its general composition is somewhat weak in the treatment of the entrance. Thus the plans of the first and second designs show two distinct principles, that of the first a straight central corridor, that of the second a central open court with circumscribing corridor, a sort of "here we go round the mulberry bush" arrangement, and nearly all competitors follow one or other of these types.

Messrs. WILLS & ANDERSON, the authors of the third premiated design, have placed their main entrance at one end of the principal front, leading to a hall or glorified corridor, 10 feet wide, from which opens the principal staircase, semicircular on plan, with the secondary stair leading to the caretaker's rooms adjoining. These are both lighted from a single central area, around which on three sides is a corridor 6 feet wide, off which open the various rooms. As in the second premiated design this arrangement of plan rather suggests going "round the mulberry bush," especially as the general offices of each department, to which of course the public need most frequent access, are impartially placed, so that it does not much matter which way visitors turn, as they will in either case have about the same distance to go, that is as far as possible from the stair and lift. In this respect the second premiated design is better, for the general offices are close to the stair. Messrs. WILLS & ANDERSON have a fairly successful elevation to The Forbury, but their other fronts are void of architectural design. This competition has not been the occasion of one of the best efforts of Messrs. WILLS & ANDERSON, and the merits of their design are still further obscured by very unfortunate colouring.

To notice, far less to criticise, all the remaining 174 designs would be more than our space would permit, but there are some that we cannot pass over, and we may as well say at once some of them in our opinion are superior to either the second or third premiated designs. We do not profess to place these in order of merit but take them haphazard as they are hung.

No. 73 has a plan of the corridor round an area type, but more direct and satisfactory than those premiated. The elevation is unfortunate in composition with a richly treated projecting pavilion on one side only of a symmetrical disposition, of which the entrance forms the centre. In detail the design is good.

No. 37 has a plan somewhat on the lines of the first premiated, but with two branch corridors from the main one, a good plan but not quite equal to the best. The front elevation and detail are excellent, though not reminiscent particularly of Reading.

No. 39 again follows the type of the winner, but a slight variation in the planning of staircase and the secondary corridor, which in this case is needed on first and second floors, renders the plan less direct and compact. The elevation to this design is quiet and refined, but would have been improved if the end pier pilasters had been carried down through the ground floor.

No. 97 is another variant on the selected type, but the secondary corridors being more extensive bring it nearly to the "mulberry bush" type. This is distinctly one of the good plans submitted and is accompanied by a powerful elevation and detail.

No. 88, with a central entrance, has managed to combine the principal features of the two typical plans, and on the first floor, but there only, has the continuous circumscribing corridor. The elevation is fair and not too municipal, but lacks the interest that a *pianta nobile* would give. The first-floor windows are right in detail, but not in scale to make them dominant.

No. 5 is a good example of the application of the winners' type. Compactness is gained by the avoidance of internal corridors to rooms of the same department, some of which are therefore necessarily corridor rooms. For example, in the County Treasurer's Department the assistant clerk cannot reach his room without going through the chief clerk's room or the general office. This is a method of planning public offices that many have followed. Apparently it saves corridors, but really the ostensible area of the rooms is diminished by the space left free for the through traffic. The elevation is quiet and refined, but suffers from a lack of principality in any floor of the four and the too great importance of the attic.

It is of course difficult in designing the elevation for a block of offices to give the greater importance to one floor, qua *pianta nobile*, that a satisfactory composition demands, and when, as in most designs, there are four floors the difficulty is increased. Some competitors have managed to provide the accommodation required on three floors above the basement, and these generally have the most satisfactory elevations, for it is easy to give enhanced height to the windows of the first floor and to pinch a little those of the second floor. Others have tried the device of a giant order, but that has produced designs usually of too important a character for the purpose of the building, for which somewhat of a domestic feeling appears to be the most suitable, or at least a compromise between stately domesticity and municipal grandeur.

No. 170 has managed by a development of the principle of self-contained departments, with rooms *en suite*, to produce a very compact plan on his first and second floor, and thus reduce the height of his building to three storeys above the basement instead of the four that most other competitors have found necessary. This, as we have explained, makes easier the design of the front, and a very satisfactory and excellent composition results.

No. 83 has taken the bold step of making his entrance to the new building in the part of the Assize Courts available for re-use with a new porch and vestibule. The result is by no means unsuccessful, although there is a somewhat wasteful arrangement of internal hall with galleries on upper floors which it must be admitted would give excellent interior effect. The elevation does not attempt to be too municipal, and suggests a dignified domestic building quite suitable for County Council offices.

No. 135 is another design whose plan is similar to that of the winner, and is quite an architectural plan, workable and internally effective. The elevation is distinctly good and the detail excellent, but almost too good for the size and importance of the building, which indeed looks to be part of a larger scheme rather than a complete entity.

No. 134 follows the selected type, and like most others of this type produces a good plan. The elevation is one of the best attempts submitted to harmonise with the existing Assize Courts without copying their design or detail.

No. 107 also follows the selected design in type of plan, but has minor faults in detail which detract from its excellence. Like many others the desire to utilise the "rooms available" in the old building has rather spoilt the plan.

No. 139 boldly refronts part of the Assize Court and makes his entrance in the re-entering angle between the new and old building. The working out of the idea leads to the lighting of a very large proportion—say quite one-third—of the offices from an internal area 27 feet by

Digitized by Google

20 feet. The elevation and detail are distinctly good, but would be improved by greater height to the first-floor windows and less to the second.

No. 69 has a central entrance leading to a corridor around a central area, an example of the "mulberry bush" type, but has a good elevation and detail.

No. 34 has a good plan with central entrance and corridor, following the type of the winning design, and one of the best elevations in the competition, an instance of the superiority in this respect of the three-storeyed front.

No. 144 is remarkable in plan as being free from any internal area, a central corridor with another at right angles being lighted from an ample staircase on an external wall. The elevation is good, but would have been better with the omission of the balcony to the first-floor windows, as this detracts from the principality that their height would otherwise have given them.

No. 70 is compact in plan with little apparent corridor and no internal area, merits obtained in part by the *en suite* arrangement of the departments, with the consequent thoroughfare rooms. The author of this design sends a very good detail drawing.

No. 66 is another plan with its entrance from the Assize Court building, and is quite a successful development of the idea. In this plan also the several departments are individually planned *en suite*. This design includes a good eighteenth-century semi-domestic type of elevation.

No. 75 is an example of the type of plan followed by the second premiated competitor, but the "general" offices and porter are rather out of the way.

No. 1 has a nice detail drawing of an originally treated adaptation of the Greek Doric as a giant order of engaged columns, but the plan is not worthy of the elevation.

No. 104 is a good instance of the central-corridor type of plan with semicircular stair off it, and is accompanied by a well-drawn detail.

No. 82 has the entrance at the side leading to a corridor around a central court, which on the ground floor is occupied by offices top lighted. The elevation is rather effective, with an excellent detail drawing, but would be better without the ventilating flèche, which is hugely out of scale with and crushes the detail of the front.

No. 165 was surely worthy of a premium. The main feature of the plan is a central hall with a light well in the middle and a gallery around with the stair off it. The elevation and detail are both good. Perhaps this design was disqualified because it has a mount that is not white.

We shall illustrate Messrs. WARWICK & HALL'S design next week.

NOTES AND COMMENTS.

IN the decision of Mr. VEREY, Official Receiver, on the case of HAWKINS *v.* The KING, there occur some important points as to the liability attaching to contractors in connection with work contracted for with Government departments. The question raised in this case was whether the plaintiffs, Messrs. HAWKINS, who under contract with the War Department carried out work that appears to have necessitated "extraordinary traffic," were liable to indemnify the Crown against claims made by the highways authorities for the "extraordinary traffic" and its damage to the roads. The learned Official Referee found that the contractor was "liable to the Crown for the amount of every claim made by a local authority upon the War Office (whether covered by a certificate or not, provided that a certificate could be got, and that there was at the date of the claim time to get it) so far as the items therein represented money expended by the authority in repairing damage done by extraordinary traffic caused by the contractor in the execution of that contract within twelve months before such claim was made, or under a contract either still in course of execution at the date of the claim, or which had terminated so far as it was capable of causing damage to roads within six months before the claim."

THE writer in the *Cornhill Magazine* whose lament that "with the death of WREN architecture begins its old age," and that the eighteenth century marks the growth of decadence due to eclecticism as opposed to the influence of tradition, appears to be scarcely cognisant of the fact that architecture to-day, as always, reflects the spirit of the times. He complains that "architecture has become the slave of fashion and an anarchy of taste has succeeded the long reign of tradition." That is to say, architects to-day do not design exactly on the lines their fathers followed, but start their inventions from some other basis, now Gothic, now Greek, now some phase of Renaissance, and follow the fashion set up by some leader of the moment. Perfectly true; and does not this reflect what is going on in other departments of national life? Not to rely for an argument upon the variations of costume, particularly women's costume, which has ever been the field of quickly changing fashions, do we not find violent changes of fashion a feature of modern life in our amusements? Ping-pong, tennis, croquet, rinking, diabolo, are for a time the universal rage till displaced in popularity by some other temporary craze. Similarly in dramatic entertainments, there is now a vogue for one form, now for another. In literature now one author and then another is the popular favourite. If the author of the article really appreciated the trend of our modern architecture, he would know that at no period in the history of English architecture was there greater virility and a higher level of achievement than at the present day.

LORD ALDENHAM in the *Great Western Railway Magazine* has been lamenting the dispersal of the interior architectural features of the old Jacobean House, No. 47 Lime Street, London, the "Compting House" of the GIBBS family, which he would have been glad to purchase and to incorporate in his house at Aldenham, only unfortunately he spoke a little too late. There does not seem to be much, however, to be regretted on this score in the hall of the Worshipful Company of Cordwainers, erected in 1788, and now being demolished to make way for a new building designed by Mr. HOWARD CHATFEILD CLARKE. The fine modern stained-glass window to the memory of JOHN CAME is to be preserved and incorporated in the new building.

THE difficulties of local authorities in dealing with low grade not to say unhealthy houses are illustrated by a case just decided at the Liverpool Police Court. In Liverpool, as stated by the medical officer, Dr. E. W. HOPE, there are thousands of houses unfit for habitation, but the housing committee are not at present in a position to deal with them all by demolition and reconstruction. Now comes the difficulty, Are these insanitary houses to be left till the finances of the city can bear the cost incident to their rebuilding? It might be possible to close them all by magisterial order, but where are the displaced inhabitants to go? In the case just decided a number of houses were condemned by a closing order in May last. The owners have reduced the number and carried out certain works to the remainder. They then applied for the determination of the closing order, and this was opposed by the Corporation on the ground that the houses did not yet come up to the standard required by the authorities, but the medical officer was obliged to admit that as the Corporation were not prepared to provide housing accommodation they felt they must allow the tenements in question to be inhabited. Under these circumstances the magistrate felt he could no longer rule that the closing order should remain in force. We all desire that the poorest should be healthily housed, but there are so many considerations to be borne in mind that counsels of perfection may readily inflict great hardship not only on landlords but on tenants, and therefore the Augean stable cannot be cleansed in a day.

EXTENSIVE additions to the building of the Glasgow School of Art have enabled the managers on the opening yesterday of the sixty-eighth session of the school to make a considerable development of its work in the adequate provision of lecture-rooms and studios for subjects previously suffering from lack of adequate accommodation. A joint course of instruction in architecture is

Digitized by Google

given in the School of Art and in the Technical College, and the joint classes form the Glasgow School of Architecture, the work of which during its five years of existence is admirably justified by the high standard of achievement reached by those who have been fortunate enough to share its advantages. Artistically Glasgow is one of the most remarkable cities of the Empire for the ability of its architects and especially of its younger men.

THE restoration by Commendatore BONI of one of the footpaths beneath the Arch of Constantine to its original level gives an opportunity once again of seeing the monument in its original proportions. In the course of the work of excavation the subterranean exits of the *Meta Sudans* have been discovered. The rescue of the relics of Imperial Rome and Italy from the accumulations of ages is a work in which Commendatore BONI has achieved most valuable results, and it is to be hoped that he may long be able to continue what he has so well begun.

ARCHITECTURE: ITS TRUE PRINCIPLES.—XVIII.

By R. OWEN ALLSOP.

THE RECTANGULAR BASE.

A GREAT point about the rectangular mass as a groundwork is that it forms a frame for the better setting-off of forms less severe. The use of rigid rectangularity in general mass gives greatest scope to perspective effects, especially to colonnades and the like. It possesses the majesty of the sheer cliff, that is lacking in more broken composition. The rectangle forms a base for square attached secondary masses or wings as transepts, giving the full contrasting value to the meeting of two planes at right angles and the light-and-shade effects. It is to be noted that all arises naturally from the rectangular plan which in itself is best suited for practical service, giving the room with right-angle corners. One main, more or less central and dominating rectangular block, in the spirit (if not actually arranged after the manner) of a cathedral nave, forms the most fitting base for axial, monumental planning. It ensures a fine main-roof mass. A building even of small dimensions, arranged as a plain rectangle composition, will always show well among neighbours wanting in unity of massing by reason of the purposeless breaking up of main lines of such. Any kind of magnificent effect can be given to the severe, plain, right-angled building, as may be seen in any country affording fine specimens of the architect's art. It is a good start, if not an absolutely necessary one, as a building of poor body and large wings immediately suggests subdivision and want of unity, such as one sees in the broken-up institution with its wards and pavilions. It is fortunate for city architecture that the sheer, plain, square wall based on a straight line is the most effective of building backgrounds (so to speak); or city architecture would be in a more hopeless condition than at present, where the only scope is a flat façade flanked by neighbours' party walls.

It must seem therefore a law in architectural design that some dominant mass is required as a basis of composition, and that this mass should preferably arise from a strictly rectangular plan, hence becoming of itself of necessity rectangular in form, for, as we have ventured to suggest before, two-thirds of architectural design must be referable to the plan. Given this prime mass of effective and imposing squareness (in the sense of right-angled corners), we can add on wings, pavilions, enhance the centre, vary the methods of flanking, mark out parts by special massing, and so endeavour, as an ulterior motive, to render the whole *one building* as distinct from a hospital-like collection of architectural units. Herein lies the great interest and problem, and the greatest difficulty, and probably one of the least studied attributes of present-day architectural design.

The effect of rectangular mass is to enhance the value of cylindrical ones, as plainly shown in sharp perspective views of St. Paul's, and perhaps observable in fig. 40.

The form of the crystal results from law. It is curious that the only suggestion of anything like the solid forms that are the base of universally admired buildings are to be found in crystals of various primitive varieties of matter. The cube, the parallelopiped, the prism, the pyramid on various bases, the tetrahedron, octahedron—the elementary geometrical solids, are exact counterparts of the forms best suited to obtaining dignity and grandeur in main architectural masses. A half crystal of a chemical compound gives the geometric form of the top of Sompting Tower. Many of the elements (the components of *matter* which is the material of the builder) give more varied geometrical figures. The whole are distinguished by those definite axes and planes of symmetry that we

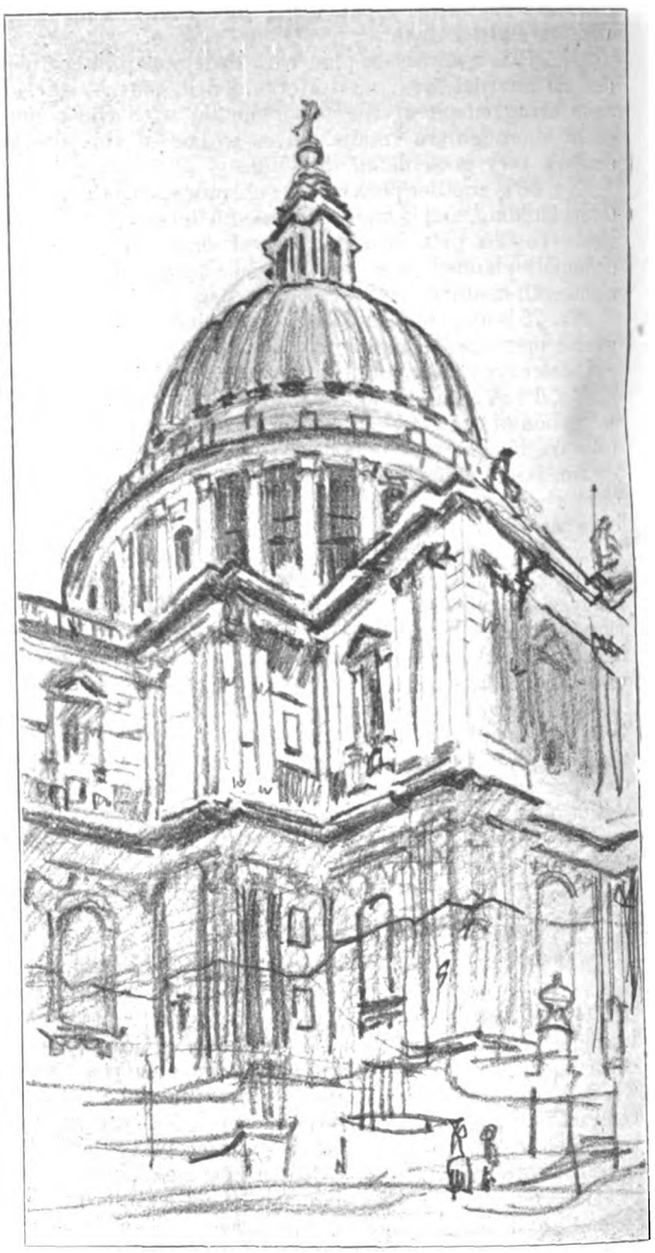

FIG. 40.—ST. PAUL'S.

have suggested must be found in all imposing architectural compositions.

This is a curious fact, leading to curious reflections. Nowhere in creation (except in the domain of crystals) is there suggestion of pure architectural form. We may take suggestions for imposing grouping from mountains, for majestic, sheer, vertical walls from the cliff and precipice, for columns from tree trunks, and for coursing from the stratification of rocks; while certain natural stone formation closely resembles actual grouped piers and moulded columns. There is no suggestion of elementary architecture found in the beaver's hut or even the wigwam of the savage. We look in vain for anything in the

Digitized by Google

vegetable world—beyond the column's trunk, which is moreover referring only to mere architectural detail. Leaves and flowers suggest symmetry and balance, and the animal world the value of one symmetrical part and the little importance—if not actual wrongfulness—of symmetrical sides or flanks. But from a selection of natural crystals dressed only by splitting on their natural lines of cleavage, we can quite easily construct a model of the main masses of any rectangular building that ever has been erected that has a high degree of architectural merit according to the universal judgment of enlightened persons. A plain, cubical mass surmounted by a prism is the beginning and end of the mass-outline of the Parthenon, ignoring of course columnar construction and projecting details, and constructing a geometrical figure by vertical planes bisecting the columns and utilising the prism for the roof planes and the triangular forms of the tympana. From such a consideration we can at once see that all attempts to construct effect of mass outline on the fretwork or wedding-cake or vase principle, must be diametrically opposed to sound principles of architectural composition and grandeur of effect. Such fretwork design can only become suitable in towers that rise out of a main composition and are seen clearly all round, as for example the Antwerp spire.

It may give to some a sense of humiliation to refer all architectural mass-form to the apparently insignificant world of crystals. A little consideration will show that this is a wrong view. The cause of the crystal is law. The end of the law is order. It is surely ennobling to work under law.

The last words of a great and good man* "all right—*all under rule*," express the true spirit of a noble worker. The laws that bring about the crystal formation were laid before the foundation of the world, and to compare crystals with architecture, is only, after all, another way of stating the fact that all architecture is based on geometrical principles—founded that is to say on eternal truths alike binding and controlling the chemical atoms and the planet in its course.

Moreover, this line of argument is justified for other reasons. The artist deals with the representation of life and the sculptor likewise; the architect models inert matter, and there is no life in the building any more than in the rock. It therefore seems unreasonable to look for hints and suggestions into the living world of plants and animals. If we deal with lifeless matter, and essay to produce a real or apparent sense of order from so-called chaotic (or what we may term the sublime) system of order—humanly called "disorder"—we do well to inquire into the question of the proportions and characteristics of the elements that comprise that which is generally classed as "matter."

Order, as we understand it, principally consists of a process of selection, whereby like things are aggregated. In the chemical processes necessary to the "sorting" of the separate elements, we find that the purified elemental substance naturally—that is, by law—arranges itself into a definite, geometrical, solid shape or form of three dimensions—as an accurately arranged stack of correctly-shaped bricks, or as a pile of round-shot arranged in the most compact formation. The then exhibited attributes are—definite shape, geometrical basis, mathematical ratio, axis and plane of symmetry.

All these properties are equally found to be the root-cause of noble architectural design—man's mind impressed on matter for definite ends and purposes.

(To be continued.)

The King's Norton Education Committee are about to erect a secondary school, and proposed to mark the occasion by a stone-laying ceremony. The Worcester county authorities have strongly discouraged the idea. They are to be asked to reconsider their decision in view of the importance of gaining all possible publicity for the school.

* Charles Kingsley.

TOWN PLANNING.*

THE advent of the Town-Planning Bill opens up a vista of reform and social progress of the very first importance.

It is a true saying that we are creatures of environment, but it is none the less true that we may, if we so desire, be the creators of our environment. Unfortunately in the immediate past opportunities for this have come to but very few, and to these without reference to ability or desire to take advantage of the opportunities conferred.

The creation of civic environment must not be allowed any longer to be regarded as a matter entirely of individual interest; it must be recognised rather as a matter of public responsibility.

In the Town-Planning Bill we have the first of what I hope will be a series of Bills directed to securing public control of environment. I may appear optimistic in saying so, but I feel that this Bill, if wisely directed and skilfully handled in its operation, can be made to exert an influence not only on the physical but also on the moral and intellectual life of the community, of a nature more real and more direct than any other measure of reform that has been placed on the Statute Books during recent years.

But to proceed to a criticism of the Bill. Several clauses call for especial attention. In drawing up the Bill there is evidence that the intention has been not so much to frame a set of conditions so definite as to exactly meet every exception and contingency that may be met with in its operation, as to leave very much to the discretion of the officials responsible for its direction: a wise course where there are wise officials. It is of the utmost importance that the positions occupied by these officials be well filled. I refer in particular to the officials in the offices of the Local Government Board.

In clause 55 the Local Government Board may make regulations which shall provide according to the Fifth Schedule, restrictions, whenever circumstances so require, on the number of buildings which may be erected on each acre, and the height and character of the buildings.

How in this practice this will be interpreted remains to be seen, but it is to be hoped that the following observations will be taken into consideration:—

That in determining the character of the buildings to go on to a certain site, whether the word character be interpreted as class, meaning factory, public office, residence or shop; or whether it be interpreted as having reference only to effect; it be borne in mind by those whose duty it will be to decide this point, that the ways in which one building or class of buildings may be detrimental to others are not confined to a few practical considerations such as rights of light, lines of frontage, &c., nor even to such considerations as would come under the head of public nuisances as those fitted to contain noisy machinery, those designed to carry on objectionable businesses, or those erected for the purpose of manufacture in the process of which are emitted an excess of smoke or noxious and pungent smells. All such may very obviously and easily bring about the ruin of a neighbourhood in a very short space of time. But besides these there are also other classes of objectionable property which on the ground of being objectionable in character ought just as certainly to be ruled out. I mean buildings which are offensive to the sense of sight; and amongst these I would without hesitation class the interminable terrace of speculating builders' design; all buildings obviously designed as advertisements, and intruding either as irregular monstrosities in form, as vicious exhibitions of colour, or as vulgar expressions of other kinds. I am aware that the result of such an interpretation might cause individual suppression, but at the same time I feel sure that individual expression at such an expense is less worth while. Let us hope that the word character will cover all this.

Again, may those who interpret the Act use discretion in enforcing restrictions on the heights of buildings. An unwise jurisdiction over heights of buildings to be erected even over one acre, may produce a scientific yard-measure sort of result quite incompatible with the varying character of the sites provided even on so small an area as one acre.

But to revert from the Town-Planning Bill to the preparation of suburban town plans. Here there are many points which should be kept in mind at the outset. First, areas for operation will have to be decided upon, and much will depend on the outline of the area selected. The outline of the areas which form the boundaries of many of our garden suburbs are very unfortunate as having no connection with

* A paper by Professor S. D. Adshead, School of Civic Design, Liverpool University, read at the National Town Planning Congress.

Digitized by Google

natural surroundings. In outlining areas for town planning the boundary should always be influenced by some natural or historic line of demarcation, as a watercourse, an old road, or the edge of a wood. Outlines which follow ridges or centres or valleys, should be avoided as these should form the centres of the divisional lay out.

The area for operation having been decided upon, the next consideration is the class of property to be erected thereon. This should be influenced by the result of a well-considered sociological survey of the whole city, which to my mind should in all cases be prepared by every town before commencing to make town plans. Such a survey would ensure each zone or district having a well-considered reference to the whole. In Germany the statistician assists largely in the preparation of the town plan. I presume that his duties are of a sociological nature, so that we have precedence in Germany for such procedure.

It would be inopportune to discuss all the considerations which are likely to govern the distribution of population about a town, but looking at the subject broadly, two alternatives are clearly presented. The first would delegate areas to distinct and separate uses, there would be residential areas for different classes and industrial areas for different industries. The second would create centres of interest at chosen points, and about each centre would be clustered dwellings for all classes, with such public buildings and business premises as immediate convenience dictated a need for. Judging from tendencies in modern civic extension it is clear that the latter alternative is generally the one which should receive our first consideration.

Glancing at the sociological growth of our larger cities it is clear that this has ever been the tendency, and a tendency which has had excellent results. Each outlying district has grown more and more to depend upon itself for immediate resource. Note how London has formed itself into separate boroughs, how Kensington, Brixton and Chelsea has each become an important shopping centre, has its suburban theatre, its library and its town hall. The same tendency may be seen in the suburbs of Liverpool, Manchester, and other provincial towns, though in a less obvious way; and so the mother city is continually throwing off fresh seedlings in her sporadic growth. It is for us to see that these are favourably planted and are supplied at the outset with all the essentials of individual existence. Each subsidiary centre would have its church, its public hall, its almshouse, its school, its shops and village green. I do not say all these, but what in modern suburban existence corresponds to such. The civic centre, the public buildings, the stations for tram and train, the theatre, the library, the club, the shops, the school. Close around these, and each with its garden, and in close proximity to a park or place of recreation, would be the dwellings of the workers. These clustering about the suburban centre would be judiciously arranged to occupy the back lands. As the one or two main roads which would radiate or circumscribe the city drew away from the suburban centres they would be aligned with the villa residences of the middle classes. Such residences would need to conform to a more formal treatment of elevation and surrounding than would be expected in the dwellings of the poor and working class, and further out, occupying the intermediate spaces, and generally well elevated between each suburban centre would be the dwellings of the rich, where stately mansions, formal in treatment, and surrounded with extensive grounds would give breathing space and form points of interest amidst the verdant richness of the suburban landscape.

The advantage of such a suburban lay out would be that it would prevent the possibility of one class of property encroaching upon and spoiling another. Individually separated, yet placed in juxtaposition, the classes could most favourably assist one another. The rich are necessary to the poor, the educated to the uneducated, the refined to the vulgar. Mutual assistance would breed organised citizenship, and diversity of interest would lead to practical attainment.

Such a general sketch would never be absolute in its concrete expression. Other factors of a geographical and historic character such as pronounced natural configuration, old roads, rivers, valleys and historic centres will react on any system, also questions involved in the realisation of special interests such as those of sport, art and recreation; these definitely separate a class.

In this country most suburban centres are already well marked out, but in their development some such well-organised system as the above must be kept in view. In planning the future of an existing town, not only is it necessary to consider the laying-out of fresh tracts of country but much thought and energy must be devoted to the destruction and abolition of what already exists. I refer in particular to slum property of any class, and also to the hideous railway encroachments, which in a money-making age have cut up the approaches to the city in a most disastrous way. The former can only be regarded for the time being as vacant land, held on a fixed but limited tenure, the length of tenure depending upon the supply of cheap land available in the vicinity. To obtain cheap land we must have improved and rapid communication so as to swell the market, induce competition, and so bring down the cost. Given an unlimited supply of easily accessible and cheap land the work of the speculating builder is doomed. When land is comparatively cheap, and not less than ten cottages are erected to the acre, the money invested in bricks and mortar compared with that invested in land is out of all proportion greater; so that the interest on the investment when taking into consideration the added improvement of a garden and general aspect is practically in favour of ten cottages to the acre, and not forty; and not only should it be immediately greater, but it would be more secure, so much so, that I prophesy that in the near future landowners will not grant leases to the speculative builder subject to the erection of property of the hideous terrace class; and so useless and decimated will that class of property become that eventually in the interests of ownership it will be found absolutely necessary to pull it down.

Our second object of attack will be the unsightly and wastefully disposed railway approach. It is deplorable that most of our large towns and many of our smaller ones should be gashed, hacked, and divided asunder by hideous embankments, or systems of arches penetrating to the very heart of the city. Such must eventually be demolished and replaced as regards main trunks where it is essential that they come into a town, by cuttings immediately under the surface of the road, or in the case of lines which penetrate and circumscribe the centre of the city, by deep laid tubes.

In conclusion let me dwell for one moment on the units of the suburb. First we have the cottage, the dwelling of the working class. Let this be a cottage in the best sense of the word, the embodiment of a simple life, its garden planted with old-world plants and bushes, and its apartments furnished every one for use. Avoid the association of Italian ever-greens, monkey puzzle trees and exotic cultures of every kind. Speaking generally these have no place here, nor has the brick fence, the asphalte path, nor the iron gate. I need say no more. We in England possess a wealth of tradition in this respect incomparable with what is to be found elsewhere throughout the world.

Let our cottages be approached by grass bordered paths, and let the roads be the simplest of well-kept tracks.

For the residence of the middle-class I would advocate a more formal and refined type of architecture than is at present usually associated with the residence of this class. I rather feel that the usual middle class residence savours too much of the glorified cottage; there should be a distinction, the manners of the middle class surely call for something more refined than the brick hearth, the open beam ceiling, the bull's eye glazing, and rustic stair. This aping of the cottage is unfair to the lower class. Without laying down any hard and fast rule, may I direct attention to the formal middle class residences of some fifty to a hundred years ago, a time when refinement of manners, scholarship and good taste attained to a very high standard amongst those responsible for building development?

In the future the houses of the rich will necessarily be in great variety of taste. Isolated, and not forming part of a scheme, each will be a scheme in itself; and not only as an incident in the landscape will they affect the town plan.

The actual system or fashion of plotting out the roads in the suburban plan will depend upon the character and style of the architecture which dominates the scheme. There are varied styles in planning roads as there are styles in architecture. Each must complement the other. The rustic cottage aligns a rustic road, and a rustic road depends on the irregular but picturesque arrangement of trees, banks and contours for the interest which it evokes.

The formal dwelling must align a formal road, which again depends for its interest on its avenue of trees, its formal gateways and garden fences, its well-kept side-walks, its regularly placed lamp standards, its seats and other furnishings.

These are some of the general principles which should control the suburban plan, but the suburb is not the only part of a town requiring attention. The Town-Planning Bill emphasises its importance at the present moment, but like America, we have need very shortly to look to our civic centres, for it is only here that architecture can fully attain the proud position she holds as mistress of the arts.

SNAP-SHOT DRAWING FOR ENGINEERS AND ARCHITECTS.

AMONG the lectures arranged to be read at the Congress Hall, Imperial International Exhibition, White City, on Saturday last ("Engineering Day"), was one by Mr. T. R. Ablett, founder and art director of the Royal Drawing Society, entitled "Snap-shot Drawing for Engineers and Architects." In the course of his remarks he said it has come to the knowledge of the Council of the Royal Drawing Society that in various branches of technical drawing, such as that of practical mapping, botany, zoology, geology, war, surgery, architecture, engineering and other constructional drawing, students with undeveloped pictorial imagination have extreme difficulty in realising the natural pictorial aspect of the objects represented by such technical delineation. The Council has therefore made special efforts to develop practical imagination through the realisation of the natural pictorial aspect at first solely as "The Art of Childhood," for the veriest baby delights in it, and later as a necessary auxiliary to other kinds of drawing which are not as readily invented by the young people themselves. To facilitate the early acquirement of all kinds of drawing the Council has made their scope and relationship clearer by lay or popular definition, analysis, explanation, and also by reproductions.

General Definition of Drawing.—Drawing is the process of producing by human efforts certain markings of a descriptive nature to serve as records and convey information in connection with pictorial, mathematical, diagrammatic and decorative work.

Analysis of Drawing.—1. The most important branches:—Pictorial drawing represents the appearance of objects observed by means of converging rays of light; mathematical drawing represents the imaginary observation of objects by parallel rays of light. The latter describes the facts of the three dimensions in connection with practical, plane and solid geometry as dealt with in the mathematics and other branches of general education, and which forms the basis of constructional drawing as used by engineers, architects and many other workers. It is by working these together judiciously that the precious gift of practical imagination is developed. 2. Subsidiary branches.—Subsidiary branches are found in diagrammatic and decorative drawing.

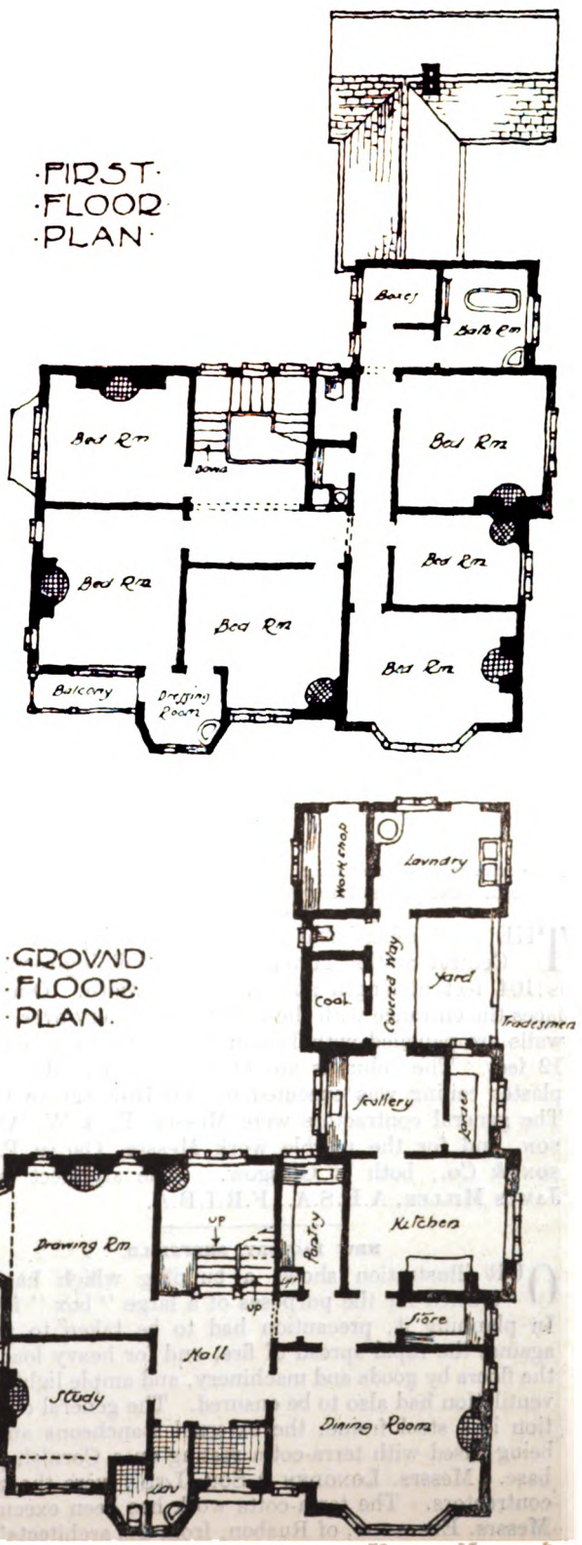
The Unbiassed Observer.—Practical imagination develops well in such unbiassed observers as are assisted in their early efforts without being interfered with.

The born artist is an unbiassed observer reflecting his environment by self-invented delineation according to the measure of his intelligence, and every intelligent child with good, serviceable eyes is to this extent a born artist. A picture is the embodiment in form and colour of an idea formed in the mind of the artist from, and based on, his observation of nature. The more realistic a picture, the more useful for scientific purposes, and realism is founded on the most expert use of the eye as an optical instrument. This self-invented delineation by the unbiassed observer is called common-sense drawing, and is the method of becoming expert by experiment.

Reproductions of the "snap-shot drawings" by young unbiassed observers were shown by lantern-slides of sheaves, umbrella, human nature study, value of structure to the artist, animal machinery, man's machinery, Achill Island.

The youthful unbiassed observer, judiciously handled, comes early to skill in pictorial drawing, and he first makes acquaintance with mathematical drawing in connection with geography. In general education all sorts of plans have been tried to found the mathematical drawing of geography on its pictorial appreciation, which through early neglect is generally found very rudimentary in the young as well as the teacher.

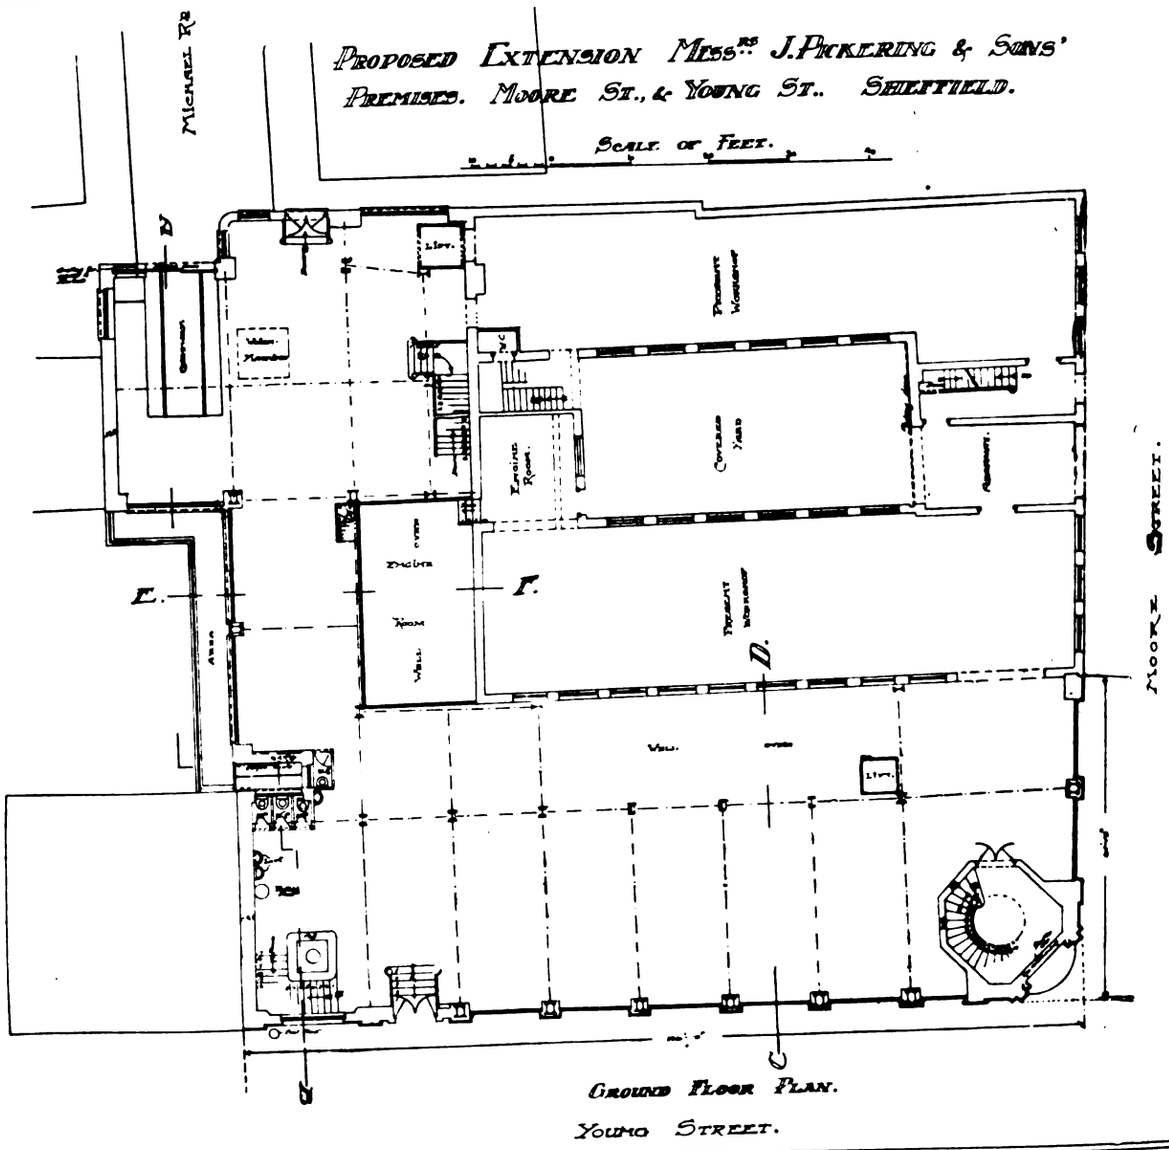
It is well known that the youth of the country, especially the boys, have a passion for the study of engines, steamships and other forms of machinery. The Royal Drawing Society desires engineers to help the Society in giving them correct information about these machines, so that those who come to be the engineers of the future may have that most useful of all faculties, "practical imagination."



An eminent engineer lately said that when any draughtsman had a difficulty in his drawing office he was told to draw the look or perspective view of the object, and this generally got over the trouble.

The "snap-shot drawing" of perspective appearance is of use to engineers as well as to many other observers.

ILLUSTRATIONS.



HOUSE, GAYTON, CHESHIRE.

THIS residence is situated on the Cheshire side of the river Dee, on the Glegg estate. The site is considerably elevated, giving an extensive view of the river and the Welsh hills. The main aspect faces south, and commands a fine view of Gayton Hall and woods. The materials are brown roof tiles, fine grit stucco with brick

base, oak half timbering and Cefn stone dressings. Oak is principally used for the interior woodwork. Messrs. WM. FLEMING & Co., of Neston, were the general contractors, and Messrs. APPLEYARD & QUIGGIN, A.R.I.B.A., of Liverpool, were the architects.

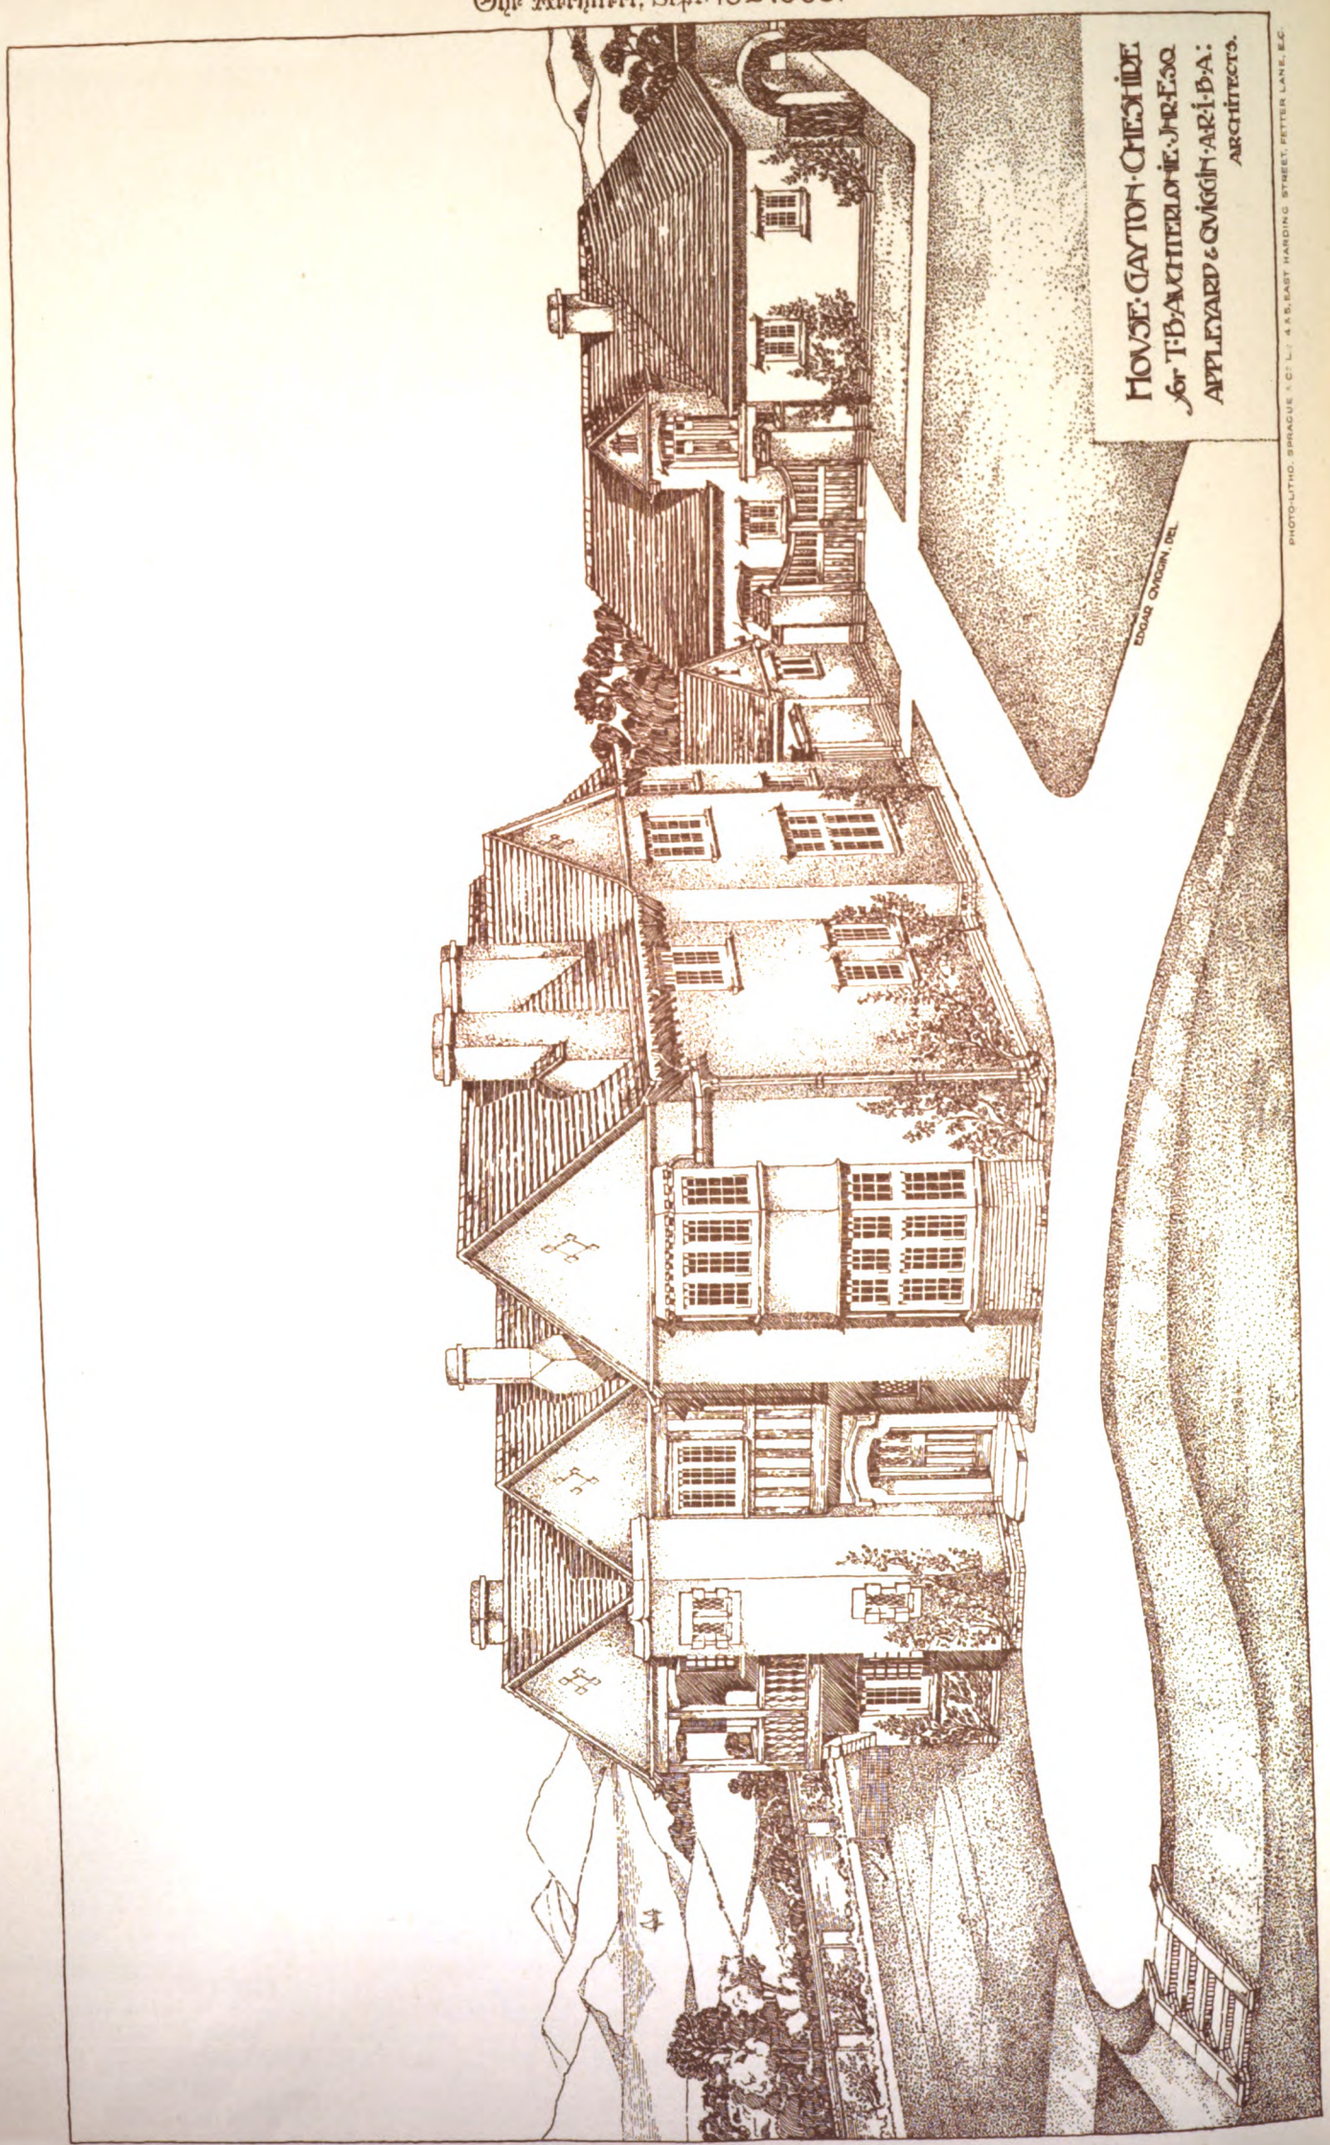
THE CENTRAL STATION HOTEL, GLASGOW.—THE LARGE DINING-ROOM.

THE most remarkable of the recent additions to the Central Station Hotel is the large dining-room. It is 104 feet in length and 47 feet in width. Our view faces the entrance with the musicians' gallery over. The walls are panelled with Italian walnut up to a height of 12 feet. The columns are of Pavonazzo marble. The plaster ceiling was executed by the Bromsgrove Guild. The general contractors were Messrs. P. & W. ANDERSON, and for the marble work Messrs. OSCAR PATERSON & Co., both of Glasgow. The architect is Mr. JAMES MILLER, A.R.S.A., F.R.I.B.A.

NEW FACTORY, SHEFFIELD.

OUR illustration shows a building which has been erected for the purposes of a large "box" factory. In planning it, precaution had to be taken to provide against the rapid spread of fire, and for heavy loading of the floors by goods and machinery, and ample lighting and ventilation had also to be ensured. The general construction is a steel frame, the external stancheons and bays being cased with terra-cotta resting on a Cornish granite base. Messrs. LONGDEN & SON, LTD., were the general contractors. The terra-cotta work has been executed by Messrs. EDWARDS, of Ruabon, from the architects' drawings. Messrs. HADEN & SONS are responsible for the heating and ventilation on the "Reck" system. The constructional steelwork was carried out by Messrs. DORMAN, LONG & Co., in consultation with Messrs. READE, JACKSON & PARRY, engineers. The architects were Messrs. C. & C. M. HADFIELD, of Cairns Chambers, 19 St. James's Street, Sheffield.

A FACADE IN KINGSWAY, LONDON.



THIS is one of the few buildings as yet erected on the east side, and is built on land formerly partly occupied by the back buildings of 63 Lincoln's Inn Fields. Thus a good site was obtained for an extensive block of offices, for which Messrs. PILDITCH & Co. prepared the plans and Mr. EDWIN L. LUTYENS designed the elevation and the artistic elements of the interior. As is required invariably by the London County Council for work in Kingsway, this façade is carried out in Portland stone. The drawing from which our illustration is taken was exhibited this year in the Royal Academy.

A Meeting of the subscribers of the Perth City and County Royal Infirmary was held on Monday for the purpose of considering a report and sketch plan of the proposed new infirmary. The directors recommended to the subscribers the adoption of a site 11 acres in extent at Western Avenue, Glasgow Road, and this was agreed to. Some time ago Mr. James Miller, F.R.I.B.A., Glasgow, was instructed to prepare a sketch plan as to how this ground might be utilised. In his report he said the buildings would consist of wards with accommodation for 120 beds, with the administrative block in the centre and the kitchen, offices, and laundry, &c., behind. Each portion of the building is detached. Mr. Miller points out that if one of the north ward blocks were omitted meantime a saving of 3,000*l.* would be effected, making a total cost of 33,800*l.*, in which case the total accommodation would be reduced to 94 beds. In preparing the estimate strict attention had been given to economy as regards materials, methods of construction, and architectural design. The directors will now take such further action as they see fit to mature the scheme of the new infirmary, and to report further to the annual meeting of the institution to be held in February next.

MODERN STYLE.

By LAURENCE HARVEY, Geneva.

GERMANY, France, and Italy are studded with new, queer-looking buildings, where fancy abounds and common sense seems to be absent. When asked what is the style of these buildings, the answer is given by Germans, Frenchmen, and Italians with the English words, "Modern Style." English has been adopted for this new architectural style, just as it is adopted all over the world for sport. Everywhere people speak of "bookmakers," lawn tennis (pronounced by Frenchmen "*lane tes nièces*," just as English sailors have made Leghorn out of Livorno), croquet, and football. In French towns you will hear even young roughs say to one another, "Allons jouer au football." The English title, "Modern Style," enjoys the same honours. Why? In England, as well as in the rest of Europe, up to 1880 architects were guided by the idea of reviving or using ancient historical styles of architecture. In France, under the reign of the first Emperor NAPOLEON, the aim was to imitate ancient Rome. Hence the colossal triumphal arch of the Etoile and the smaller one of the Carrousel. Hence also the building of a temple of fame surrounded with a colonnade of Corinthian columns. It is now used as a church under the name of Eglise de la Madeleine. For the Ministry of Foreign Affairs an immense palace was erected along the Seine on the lines of the Colosseum of Rome, with the three storeys of arches and columns one above another. Evidently the great French Emperor wished to suggest by his public works on Roman precedents that he was himself a successor of the ancient Roman emperors. In private dwellings Roman architecture could hardly be adapted, and architects were content with repeating the different forms of the Renaissance which were developed in France. Reaction against the too great playfulness of the architecture inspired by the free and easy ladies of the Court of LOUIS XV. was the cause of the severe yet elegant style of building created in Paris under the reign of the unfortunate king LOUIS XVI. Windows became devoid of all mouldings, and depended for their effect solely on harmonious proportions. Sculptured ornamentation was scarce, but placed with much taste where it could give point and interest to the building. This style was continued in a somewhat heavy fashion in the architecture for private residences and houses to be let in flats during the reign of NAPOLEON I. and the succeeding reigns up to LOUIS PHILIPPE, or, say up to 1848. With NAPOLEON III. architecture began to flourish again. Innovations were tried in different directions. Engineering began to make itself felt in architecture. The Central Markets of Paris were constructed entirely of iron, and offer the most successful example of iron architecture, for the Paris markets are not only convenient, but are really works of beauty. Archæology had also its say. Several eminent architects endeavoured to design modern buildings in the spirit in which ancient Greek artists would have worked if they had been living in our times, in the presence of our actual requirements. Such was the origin of the Bibliothèque Ste. Geneviève near the Panthéon, the new Law Courts facing the Pont Neuf, the reading-room of the public library in the Rue Richelieu, and of several other monuments of an equally distinguished character. They were really innovations in architecture, for the aim of the authors of these great works of art was not to copy the motives or the details left by the Greeks, but to be inspired with their spirit. In both the Bibliothèque Ste Geneviève and in the National Library iron work is freely used, undisguised, for the authors believed that if Greek artists were living now they would never think of disguising either their materials or their means of construction.

Gradually the Court of NAPOLEON III., ally of England in the Crimean War, intimate friend of Queen VICTORIA and Prince ALBERT, became more and more magnificent, and began to vie with the great displays of luxury of even LOUIS XIV. This state of things has found its artistic expression in the Paris Grand Opera House, which cost nearly three millions sterling to erect. It reminds one of the architecture of the great monarch who built the Palace of Versailles, but it differs therefrom by a liveliness of outline and a striking self-advertisement of form and colour which reflect the life of our modern democracy. Altogether the Paris Opera House was a most original building, but it did not start a new style of architecture. As to the so-called "Modern Style," it is about ten years old in France, and that is all we can say about it for the present.

In Germany the last century began with a revival of Greek architecture in Berlin and in Munich. This revival consisted in copying and adapting Greek details of architecture to modern requirements. In Berlin this was done with singular taste by an artist of the name SCHINKEL. He had caught the picturesque spirit of many a Greek building or group of buildings. Can there be anything more fanciful and picturesque than the group of small fanes called the Erechtheum, with the small gallery of caryatides placed in one corner and dedicated to PANDROSE? The Propylæa must have been also picturesque and far from severely symmetrical. One of the best known of SCHINKEL'S works is the Old Museum of Berlin; another is the Theater, of elegant outline, but spoilt by conventionality and sameness of details. Munich is a vast receptacle of copies from all kinds of buildings.

Dresden possessed several examples of German interpretation of the French Louis XV. style, and SEMPER, in about 1840, designed for it a kind of refined Roman architecture for its Museum and its Opera House. The Opera House was, in fact, as much as possible on the lines of a Roman theatre, such as the Theatre of Marcellus, with a circular façade surrounding the house. This Opera House was burnt down, and another was erected in its place from the designs of the same architect SEMPER, but on totally different lines. The general scheme was that advocated by the great composer RICHARD WAGNER. The now existing Opera House is surely more original in character than the former, and perhaps more practical and comfortable, but it is, we believe, far less harmonious.

Although Austria has been kicked out of the German Empire, we may fairly consider Vienna as one of the German artistic centres. It is German, but very materially modified in spirit by the numerous races of men of which Vienna is the capital. Here men in whose veins flow Italian, Czek, Hungarian, Slave, and other oriental races, even Turks, are at home, and therefore Viennese art has a suppleness, an adaptability to all tastes which one would vainly look for in purer German regions. Vienna creates objects full of taste, to which there are no precedents. We all know Vienna chairs, so elegant, so light, yet unbreakable, thanks to the use of wood curved by steam. In architecture Viennese art creates works in all styles. Greek architecture is used with much cleverness in some of the largest public works, and to Viennese art must be attributed that jewel of Greek art applied to a modern building, the Academy at Athens. Gothic, inspired by the splendid cathedral of St. Stephen, has found also clever adaptations in several public buildings. Then SEMPER of Dresden was called upon to work out his ideas in Vienna, where by the construction of two museums and a theatre he produced an *ensemble* of monuments to be compared to the ancient Forum of Rome. At the present time "Modern Style" of a certain kind is all the fashion in Vienna.

In Italy, after the establishment of the Italian Government in Rome, public and private works were started on a large scale. Like all buildings in Italy, they were of large proportions, but in every other particular most commonplace—mere unintelligent copying of old work. Yet genius abounds in that country. In Turin, the ancient residence of the Italian Royal Family, was erected the so-called Mole Antonellianum, one of the highest buildings in Europe, some feet higher than the cupola of St. Peter's at Rome. It is a marvel of constructive ability; the whole seems carried on apparently thin walls and gracile piers, yet is so stable that even the earthquakes that have done some damage to other buildings of Turin have not affected this one. It might be quoted as an example of a modern style, for nothing similar had ever been attempted before, but it remains unique of its kind, as nobody has ever attempted since to vie with the great work of ANTONELLI,

Digitized by Google

and he himself died before the completion of his building. It seems that in this work a new principle of construction has been adopted, and that the elasticity of materials plays a great part in the structure, the whole being built of carefully selected bricks. Iron appears also to have been used not as a support, but as ties in the brickwork to counteract thrusts. At all events, this building is too scientific to ever become a popular model for architects, and had no chance of being the starting-point of a modern style. Rome is the political capital of Italy, but for wealth and go Milan far surpasses it. The gallery Victor Emmanuel, a kind of Burlington Arcade of immense dimensions, has served as a model to others in several parts of the world. Although novel in its general conception, it uses simply Classic architecture for its walls, and exhibits in its roof bold iron arches which are to be found elsewhere. Some of the new houses which surround the Castle are magnificent by their colossal dimensions and by the costliness of workmanship. They remind one of the Palace Strozzi at Florence, with its diamond-headed stone facings; but with this difference, that in Milan the entire building is faced with granite, exhibiting every kind of surface from the roughest hewn block to the most polished mouldings, and producing thereby most piquant and harmonious contrasts. The freedom is very near to what we call "Modern Style," still it remains well fixed to moorings of the past. Florence has too great a past to ever think of changing it for anything new, and Venice possesses an architecture so fanciful that our "Modern Style" falls flat by the side of it.

In England the noble and the wealthy have been brought up for centuries in the worship of Greek language, literature, and art by the University of Oxford. The lesson has been pushed home by the delivery of great plums in the form of headmasterships worth a thousand pounds a year and upwards, by exceptional good livings in the Church, and even by bishoprics at ten thousand a year to those happy scholars who had been eminent in the manufacture of Greek verses. The veneration for everything Greek has filtered down to the masses, and it has come to pass that translations of HOMER were found in shopkeepers' hands, and some sayings such as "When Greek meets Greek, then comes the tug-of-war," have passed into the common language of even the lower orders. Favoured by this state of public opinion, when STUART and REVETT at the end of the eighteenth century went to Athens and brought back measured drawings of all its principal remains, their work met with great success. Architects began immediately to dip therein to find architectural features for the buildings they had to erect for their aristocratic clients. The reasoning for this kind of employment of Greek features was simply this: everything Greek is perfect. If we produce a building made up of Greek features, this building made up of perfect parts will be, of course, perfect. Hence the numerous mansions in Belgravia and elsewhere with Greek porticos, some Ionic, some Doric, some of prehistoric heaviness, like those of the Temple of Paestum, forming a most amazing jumble of grand monumental features and everyday practical objects such as windows 12 feet high and several storeys, a jumble of which present architects feel somewhat ashamed when showing these mansions to strangers. But the acme of ridiculous unfitness of architectural features is shown when Greek styles are used in building Christian Church of England churches, such as St. Pancras and St. Philip's Chapel, Regent Street. In the former on each side are porticos supported by caryatides, exact copies of the Temple of Pandrose. If these marble ladies could think, they would wonder what service they rendered to the Church, or in what way they were connected with the Christian religion. Equally absurd is the delicate Ionic portico at the entrance, crushed by the tower immediately behind it. In the chapel in Regent Street we have the Choragic Monument known under the name of Lantern of Demosthenes doing service as clock tower above the entrance, to the intense amusement of foreign artists and the painful disgust of all men of taste.

Sir CHARLES BARRY introduced an architectural model to follow, much more in keeping with modern requirements, when he designed the Reform Club and the Travellers' Club in Pall Mall. Both are derived from the famous Palazzo Farnese in Rome. In our opinion Sir CHARLES BARRY's works are superior to their model, and exhibit perfectly good taste and fitness for their purpose. There is nothing redundant or useless in this architecture. It consists in plain walls pierced by doorway and windows. The windows are simply framed with mouldings and crowned with cornices useful for their protection. The whole building is crowned by one rich cornice. The beauty of such architecture depends entirely on the harmony of proportions in every part and detail. But to be effective it must deal with lofty rooms ranging from 24 to 30 feet from floor to ceiling. In private dwellings such as one has in London, that architecture is apt to look very tame and uninteresting. Here the Gothic Revival has rendered greater services than the so-called Classic styles.

It is, in our opinion, the adoption and practice of the Gothic style in all its branches that has at last given England the lead in art. For there is no doubting it. Paris is no more the centre towards which artists look, but it is London. What is called Classic architecture is founded on Roman architecture, even when adopting Greek details as in the church of St. Pancras. Roman architecture is based on false principles. It separates construction and decoration in two different operations. The structure is one thing which may exist without decoration; the decoration is another thing which may cover the structure as with a mantle, hiding it behind its folds. This decoration, conceived apart from the requirements of construction or convenience, was based on geometrical regularity of recurring parts, and being therefore deficient in suppleness tyrannically governed the whole building, so that convenience had often to give way to the cast-iron scheme of decoration. In Classic architecture windows of similar size and decorative importance may light a hall, a closet, or a staircase. Symmetry, *i.e.* the exact repetition of the same features right and left of the centre, is usually insisted upon whether these parts serve inside for similar uses or for very different ones. Kitchens may be made to balance salons or libraries. Some public buildings can accommodate themselves to the exigencies of the Classic style. It is perhaps best of all applied to barracks. But for private dwellings such as we have in England, where everyone lives in his own house, the Classic styles spell artistic death.

Gothic architecture does not mean what the public has long believed, viz. a certain form of window or of roof. It means simply that construction and decoration form one inseparable whole. An observation will make this clear. All over the Continent you will see the façades of the finest houses disfigured by the rainwater pipes. These come down from the roof in front of the wall, wherever wanted, and cut through cornices and strings most ruthlessly until they reach the ground. They are painful eyesores; but people through habit take no notice of them. This exhibits the failure of Classic architecture when the necessities of structure cannot bend themselves to its ideas of decoration. On the other hand, we remember a simple London jerry-builder who wanted to build a pretty villa using the following device. He placed his water pipes at the outside angles of the house so as to appear as so many delicate ornamental shafts. This builder was, in this instance, putting into practice the true principles of Gothic architecture without knowing it. But architects for a long time limited their revival of Gothic architecture to its outward forms, and to certain structural schemes which were dependent on the requirements of the Middle Ages, and on its means of construction. For instance, small materials were usually used in the Middle Ages, because deficient roads and means of conveyance did not allow of any other. Small panes of glass were also used because large ones could not be made. In copying these features of the old Gothic remains, architects were doing good work in the domain of archæology, but their efforts, as long as the spirit of Gothic art had not been grasped, were bound to end in death.

Digitized by Google

Happily, London offers problems to solve in which traditional architecture, be it Classic or Gothic, is bound to break down. In the narrow lanes of the City where wealthy merchants have their counting-houses, the getting of the greatest amount possible of light was of paramount importance. This had to be done through window space, for electric lighting had not yet been invented. Through the use of iron stanchions and girders the façades were changed into one vast expanse of glass, where the walls were reduced to the piers which divided one house from the other. Even the breast between the floor and the window-sill disappeared; a counter ran along the windows, and the space under the counter was added to the ceiling of the floor below. Merchants required the adoption of these structural devices, and yet wished that their warehouses should have a striking architectural appearance. Hence came all kinds of odd architectural devices, some clever based on Gothic principles, some based on no principles whatever, except that of adopting traditional architectural features wherever feasible. These went under the name of the Queen Anne style. The Queen Anne style had hardly any models to follow, for what remains of that period is very little, and that belonging to mediocre buildings. Thus the "soi-disant" revival of Queen Anne architecture was the starting-point of the liberation of architects from all precedents. At first it gave rise to fantastic follies, where neither harmony of form, nor proportion, nor even common sense in structure were to be found. But, thanks to the long training English artists have had in the Gothic Revival, the Queen Anne style has at last given rise to original architectural works of real value, where the principles of Gothic architecture are followed, but where its Middle Age features have been replaced by others more in keeping with our wants and means of construction. These real works of art are in our opinion the origin of the "Modern Style" which has started the artists of the Continent in the wake of England. For the present, Continental work in the "Modern Style" is full of incongruities. The suppleness of English architecture hardly fits the immense barracks seven storeys high let in flats either in Paris or Vienna. When bow-windows, adopted from the English, go through seven storeys, they produce a very different architectural effect from our own. Most of the Continental architects still continue under the name of "Modern Style" the absurdities of Classic architecture, and even invent features which are contrary to convenience or good construction. But time will clip the wings of those who have gone mad with their newly acquired freedom, and it is to be hoped that the "Modern Style" born in England will bring us soon into a real wholesome state of art all over the world.

THE AGE OF STONE CIRCLES.*

(Concluded from last week.)

IV. *Excavations in the Position of the Ancient Southern Entrance.*

CUTTING III. having given us no evidence of the position or existence of a southern entrance into Avebury, we found it necessary to pay attention to the area to the east, on the other side of the high road, both near the two large standing-stones of the outer circle on the property of Lord Avebury and in the position of the plantation of beech trees owned by Captain Jenner, the two properties being divided here by a barbed-wire fence. The trees were noticed to be planted on a slight ridge so near the road that it was thought possible that it might be the result of a collection of rubbish from the highway and elsewhere, and especially as the position is covered on the south by the end of the outer vallum which appears to obstruct any direct approach to the most northern remaining stone of the Kennet Avenue. But it was, on closer examination, observed that the slight ridge also extended towards the north into the meadow in the direction of the space (24 feet) which exists between the two remaining standing-stones of the outer circle.

(*a*) *Cutting IV.*—Forthwith we made a cutting (No. IV.), length 47 feet, width 5 feet, approximately at right angles to the ridge and 23 feet from the most westerly of the standing-stones. Here we reached the solid chalk in the middle of the cutting at a depth of 2 feet from the turf, and there appeared to be no sign of a continuation of the fosse in this position. The same depth was maintained to the most easterly part of the cutting, but there were occasional dips in the chalk which appeared to have no special significance. At 28 feet from the eastern end there was a step in the solid chalk down to a depth of 3 feet from the surface; at 33.5 feet another step to a depth of 4 feet from the surface; then a level floor for about 5.5 feet, followed by a gradual slope downwards to a depth of 4.5 feet. Having almost reached the hedge, we could go no further. But we had struck the causeway and what appeared to be steps down to the brink of the ancient fosse at its termination on the west of the entrance.

A large number of shards, glazed and unglazed, were found between the turf and a depth of 18 inches in the middle parts of the cutting, all of which appeared to be mediæval and later ware. In the deeper part on the west a few pieces of brown pottery, which we regarded as mediæval, were found in or on a distinctly blackish-brown seam of mould, the result probably of disturbance at such a time as the modern bank and hedge were made.

(*b*) *Cutting V.*—The next cutting made was close to the fence on Captain Jenner's property. The western half was cut 5 feet wide, the eastern 3 feet. It was begun close to the road fencing and continued in an easterly direction for a distance of 54 feet. At 29 feet from the eastern end the solid chalk was reached at a depth of 1.4 foot from the surface—the level of the ancient causeway. From this point eastwards the surface of the ground sloped towards the eastern fosse; likewise the solid chalk sloped downwards gradually, not evenly, but in rough shallow steps. At 50 feet from the western end of the cutting the solid chalk shot down suddenly at an angle of 46°, at which point the brink of the eastern fosse was undoubtedly reached. The western end of the cutting is more difficult to describe, because we met with a modern earthenware drain-pipe, for draining the surface-water from the modern road into the eastern fosse, the placing of which had destroyed the contour of the solid chalk as left by the constructors of the causeway.

(*c*) *Cutting VI.*—Another cutting (length 56 feet, width 2.5 feet) was made close to and parallel to the barbed-wire fence, and on Lord Avebury's side. This revealed the solid chalk running level for a length of 26 feet, the nearest part of the surface of the turf being at a depth of 1.6 foot. At 19.5 feet from the west end of the cutting the solid chalk dropped in two steps towards the western fosse, in the same manner as described in Cutting IV. At the E. end of the cutting the chalk sloped off very gradually.

(*d*) *Cutting VII.*—This narrow cutting was dug amongst the beech trees on the Jenner property. The length examined was 50 feet, but a part in the middle had to be left untouched on account of the large roots of the trees. This cutting gave clear evidence that the causeway was 24 feet wide at the top in this part, and at a minimum depth of 1.8 foot from the surface. From the margins of this ancient road of solid chalk rough steps downwards were traced in both directions. In the eastern half the brink of the fosse was reached at a distance of 14 feet from the eastern margin of the top of the causeway, from which point the solid chalk had been cut abruptly downwards at an angle of 51° into the depths of the fosse below.

No relics of datable importance were found in any of these cuttings.

V. *Excavations round a Prostrate Stone.*

The fallen sarsen stone chosen for examination this year is one of a group of five (two standing, three fallen) forming the south and south-west portion of the southern of the two inner circles. It is the most southern of the remaining prostrate stones of this circle, at a distance of 144 feet to the north of the most western of the two standing-stones near the entrance. Before excavation the stone was seen to have fallen in a southerly direction, the north end being considerably covered by turf. The digging was carried down to the solid chalk on all sides except the south and south-west.

This digging proved (1) that the stone measured 16½ feet long by 12 feet wide; (2) that it had fallen in or since mediæval times; (3) that a socket-hole had been cut into the solid chalk to a depth of 1.5 foot, roughly shaped to receive the base of the stone; (4) that for additional support the

* Abstract from report of the committee, consisting of Dr. C. H Read (chairman), Mr. H. Balfour (secretary), Lord Avebury, Professor W. Ridgeway, Dr. J. G. Garson, Dr. A. J. Evans, Dr. R. Munro, Professor Boyd Dawkins, and Mr. A. L. Lewis, appointed to conduct explorations with the object of ascertaining the age of stone circles. Drawn up by the Secretary.

Digitized by Google

stone had been packed round with a considerable number of blocks of sarsen measuring from 4 inches to 16 inches across; (5) that the base of the stone had been set at a depth of 4.3 feet from the present surface of the field; and (6) that the base of the stone in its fall had kicked out in a northerly direction only to the extent of 2 feet.

A number of shards were found in this excavation, but nothing was apparently of earlier date than Norman times. Between the surface and a depth of 2.5 feet and above the level of the socket-hole cut into the solid chalk this mediæval pottery appeared to be plentiful enough to indicate the former existence of some kind of a dwelling close against the stone, and it is possible that shelter for a number of years together may have been taken in close proximity to these huge standing-stones. Some of the pottery was found under the north end of this prostrate stone; it was, however, observed that the shards were close against the stone, and none below the level of the natural bed of the solid chalk.

A scale plan and two sectional diagrams were made of this excavation.

VI. *Animal Remains.*

Last year were found the remains of ox (of two sizes), horse (of two sizes), sheep, red deer, ? roebuck, pig, dog, fox, ? wolf, and fowl. Some of these were kindly identified by Mr. E. T. Newton, F.R.S.

Besides the red deer antler picks and the shovels of *scapulæ* previously recorded, the following animal remains were found this year:—

Cutting II.

Ox.—Humerus, depth, 6.3 feet in Roman stratum; tibia with ends missing, depth 9.5 feet in bronze age stratum; part of radius of a young animal, depth 18.5 feet on bottom of fosse; metacarpus of large ox (length 240 millimetres; estimated stature 4 feet 9 inches), depth 7.5 feet in Roman stratum; two digits, depth 7 feet.

Red-deer.—Two pieces of tine of antler, depth 8 feet in mixed silting (No. 121 in section); smooth piece of tine of antler, depth 10.2 feet at bottom of mixed silting (No. 127 in section); part of a metacarpus, depth 9 feet.

Mole.—Scapula and sternum; depth not recorded.

Toad.—Ilium; depth not recorded.

Cutting III.

Three teeth of horse; depth, 9.5 feet in Roman stratum.
Astragalus of ox; depth, 9.5 feet in Roman stratum.
Digit of red-deer; depth, 11.5 feet in mixed silting.
Scapula of sheep; depth, 18 feet in chalk rubble.
Lower jaw of dog, smaller than a retriever; depth, 4.5 feet.

VII. *Concluding Remarks.*

The season's work, considering its short duration of three weeks for an undertaking of such magnitude, has in many respects been more interesting and eventful than the opening excavations of 1908. The main results of 1909 embody (1) proof of the existence and position of an ancient entrance into "the Temple" from the south, *i.e.* from the direction of the Kennet Avenue, and (2) a considerable strengthening of the evidence obtained last year towards solving the difficult problem of the date of construction of Avebury, or, at any rate, of the great fosse surrounding the circles. The finding of a worked flint knife with every appearance of great age, and of typical Neolithic form on the bottom of the fosse, is, we think, almost sufficient in itself to assign Avebury to the Neolithic period, rather than to the early bronze age—to which period Stonehenge is referred on fairly strong evidence.

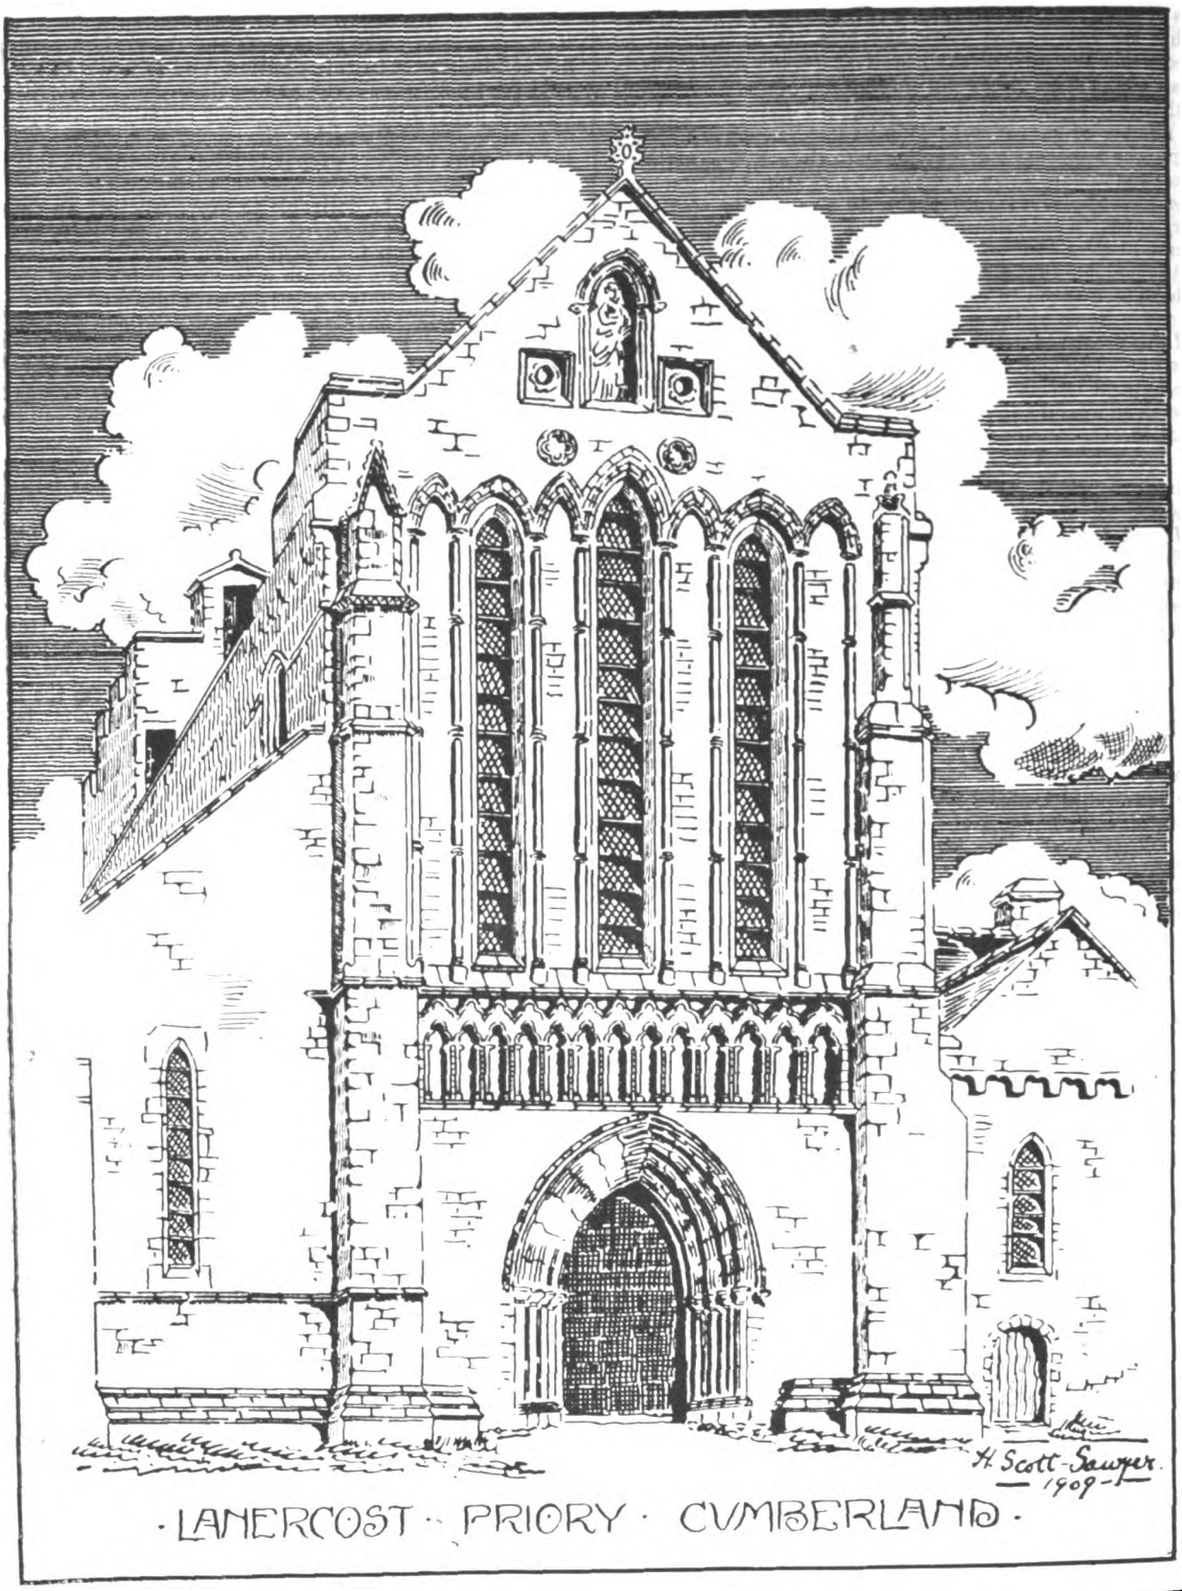
It is also necessary in considering date to draw attention to the position of the pottery of bronze age type, most of which occurred about half-way down in the accumulated silting, showing that it became deposited when the fosse had become filled to a considerable extent; and some of the early British pottery was found in the mixed silting immediately below the Roman stratum.

In addition to the knife the bottom of this vast fosse has revealed several picks of antler and shovels of bone to the exclusion of other tools, and although there is no reason why such implements should not be used in later times, those found at Avebury are of precisely the same type as those of undoubted Neolithic age discovered in some quantities at Cissbury, the Grime's Graves, and in the Neolithic pit at Maumbury Rings. We have now little or no hesitation in regarding the fosse of Avebury as being of Neolithic construction; but it would be highly desirable, if not advisable, to make one or two cuttings more into a fosse affording the variety of interest which the Avebury one does. It must have been a most imposing sight—never to be blotted out from one's memory—to see that stupendous fosse open to the bottom all the way round.

Now that we know the position of the southern entrance it would be highly interesting to excavate the rounded end on its eastern side. The beech-trees and the modern road would not be hindrances in this position, and it would be necessary only to remove some scrub and small bushes. The silting not being so high as in the parts already examined, and probably at no time under cultivation, the labour entailed in re-excavating this part would be proportionately less than in this year's cuttings.

It would also be desirable to prove whether an entrance-causeway exists at the north of Avebury, and there are other details to clear up in regard to the southern entrance. In the latter work this year we were pressed for time, and were hindered in determining the exact width and form of the causeway throughout its whole length, and our work was also impeded by the plantation of beech-trees.

As far as the causeway could be examined, the top, found at an average depth of 1.7 foot from the surface, was about 24 feet wide. On either side the level of the solid chalk gradually receded as if sloping off to meet the upper margin of the walls of the fosse in the form of rough steps not always well defined. The brink of the eastern fosse was followed in two places only. On the west such obstacles as the wooden fence, the bank and hedge, and the road itself, prevented any exact determination of the manner in which the western fosse finished and the causeway began. However, the existence of the entrance-causeway is a proved fact, the portals to the central area being represented by the two great standing-stones of the outer circle still in their original position.

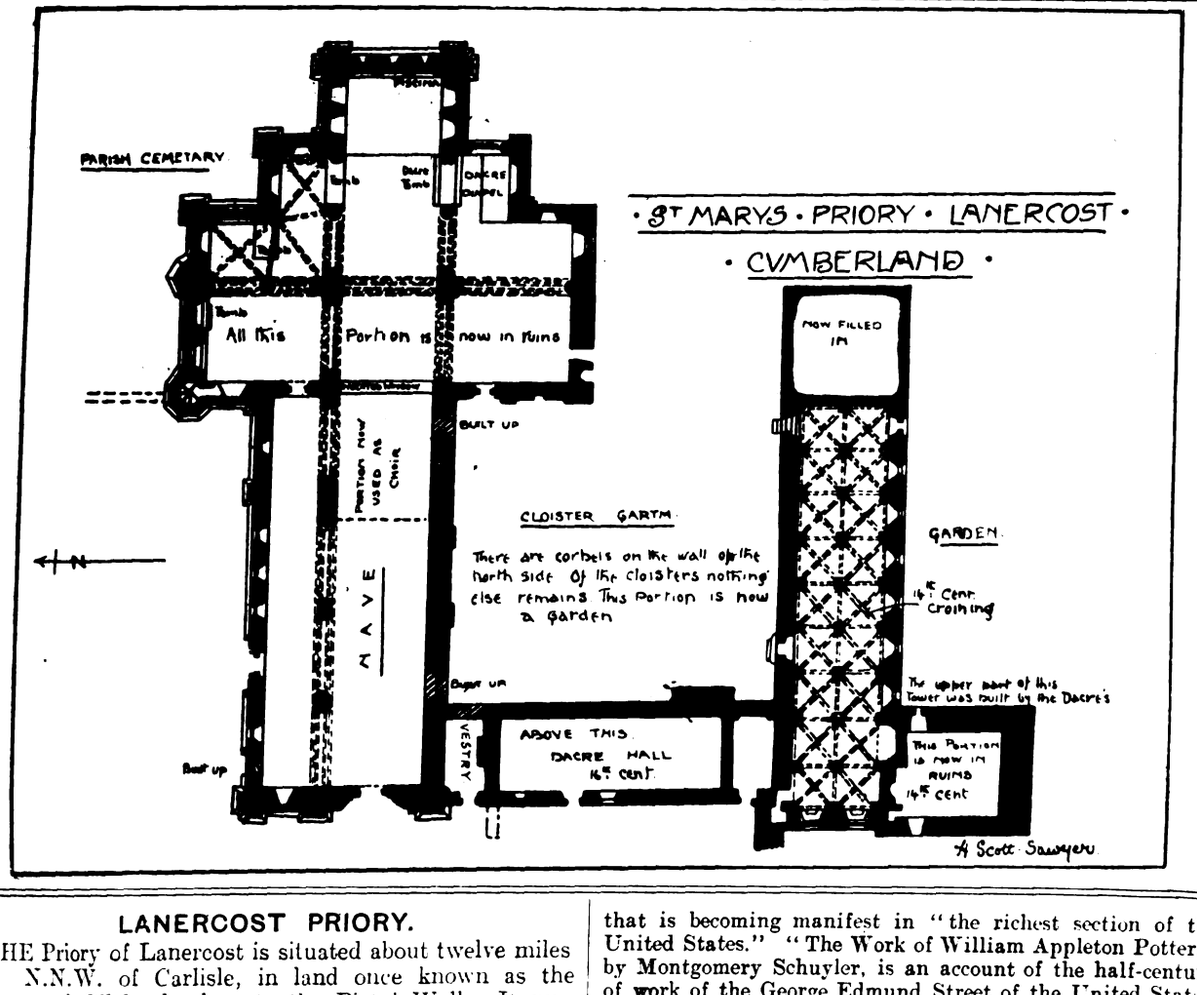


The vallum now remaining nearest to the causeway would appear to have obstructed the entrance-way from the Kennet Avenue, but this is not really so, for allowance must be made for the silting down of the material composing the vallum at its end, forming a talus, and for the fact that other beech-trees have been planted in this position, caused obstruction, and gathered round them a certain amount of decayed vegetable matter.

PREHISTORIC ANTIQUITIES IN MALTA.*

EXCAVATIONS have been conducted by the Government of Malta on the Corradino Hill, in which the co-operation of the British School at Rome has been cordially welcomed, and its investigations assisted in every way; the supervision has been entrusted to the Director of the School and to Mr. T. E. Peet, Student of the School, assisted by the constant co-operation of Dr. T. Zammit, Curator of the Museum. The great megalithic buildings of Gigantia, Mnaidra, and Hagar-Kim, which Dr. Arthur Evans considers to have been buildings of a sepulchral character in which a cult of departed heroes gradually grew up, and other smaller prehistoric monuments of the islands, have been carefully described by Dr. Albert Mayr, though others have since become known, but excavation was needed in order that many essential facts might be ascertained. The investigation of the rock-cut hypogeum of Halsaflieni, the architectural features of which imitate in the most surprising way those of the sanctuaries above ground, has for the first time produced an adequate series, available for study, of the prehistoric pottery of Malta; for from the excavations of Hagar-Kim but little has been, unfortunately, preserved. Dr. Zammit and Professor Tagliaferro will shortly publish adequate descriptions of the hypogeum and its contents. Of the three groups of megalithic buildings on the Corradino Hill, two had been already in great part excavated in the nineties, and the complete clearing of the upper one, which apparently was of a domestic character, was the first work undertaken in May. Its plan is extremely irregular, and much of it can hardly have been roofed unless in thatch or woodwork. A considerable quantity of pottery was found, very similar in character to that of Halsaflieni, and belonging, like it, to the late neolithic period. It has some affinities with pottery recently found at Terranova, the ancient Gela, in Sicily, but in many respects is unique. Many flints were found, but no traces of metal. A stone pillar was found in one portion of the building, some 2 feet 8 inches long and about 10 inches in diameter, which may have been an object of worship. The excavation of a second and smaller group, nearer the harbour, had been already completed by Dr. Zammit and Professor Tagliaferro; but a third, further to the south, on the summit of the ridge, had never been examined, and it, too, was thoroughly investigated. An even larger quantity of pottery of the same character was found, with flints and

* A report made to the British Association at Winnipeg by T. Ashby, M.A., D.Litt.



Digitized by Google

fragments of stone basins, &c. It approximates more in style to the larger megalithic buildings of the island, and has a façade with a more pronounced curve than at Hagar-Kim, constructed of very large blocks, but much ruined. The interior consists of several distinct groups of rooms (often apsidal) not intercommunicating. The construction is of rough masonry, with large slabs at the bottom, and smaller blocks higher up; the walls begin to converge, even at the height (5 to 6 feet) to which they are preserved, as though to form a roof. Into one of the rooms a very curious trough has at a later period been inserted: it is cut in a block of the local hard stone, 8 feet 9 inches long, 3 feet 8 inches wide, and is divided by six transverse divisions into seven small compartments, which show much trace of wear. The object of it is not as yet apparent. Another more carefully constructed room, perhaps contemporary with the trough, has its walls partly of large slabs, partly of narrow pillar-like stones. The floors of these rooms are sometimes of cement, sometimes of slabs. Many bones of animals were found, but only one human skeleton, and that in disorder and at a comparatively high level. The use of standing slabs at the base of walls, with coursed masonry above, visible in these buildings, finds its parallel in the Giants' tombs at Sardinia, the prehistoric huts of Lampedusa, and in many other places.

A Statue representing the robed figure of the late Archbishop Maclagan, of York, is to be placed on the east side of Selby Abbey's new tower balustrade. Other statues that are to be placed there are of King Edward, William the Conqueror, and Abbot Hugh de Lacy, who holds in his left hand a miniature model of the first abbey at Selby, which he built.

LANERCOST PRIORY.

THE Priory of Lanercost is situated about twelve miles N.N.W. of Carlisle, in land once known as the Barony of Gilsland, close to the Picts' Wall. It was consecrated in 1169 A.D., and dedicated to St. MARY. The west front is of a very simple design, but the proportion is good. The west door is a very good example of the Early English, and the mouldings, springing from circular caps, are formed upon a square order. Above the doorway are thirteen niches, and at one time very probably they had sculptured figures of Our LORD and His twelve apostles. In the gable within a recessed niche is a sculptured effigy of MARY MAGDALEN, carrying an alabaster vessel, and kneeling before her in a supplicating attitude is the figure of a monk. As is common with Augustinian buildings, the nave has only one aisle, which is on the north side of the church, and in it the vaulting is a beautiful example of the early development of the English vaulting system. The choir, now in ruins, contains some very interesting tombs, &c., and the plan of the priory is cruciform.

Our sketch and plan are by Mr. H. S. SAWYER, 12 Howard Place, Carlisle.

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *American Architect* specially devotes itself to description and illustration of the architecture of Atlanta, Georgia, which is practically a new city built since the civil war of forty years ago. The most important building illustrated is the Forsyth Theatre and Office building, a combination of theatre and business premises, of which Mr. A. Ten Eyck Brown is the architect.

La Construction Moderne illustrates a private house or "petit hotel" in the Rue de la Faisanderie, Paris, M. Blanche being the architect. This is a typical French design full of refinement and free from all eccentricities or affections of "l'art moderne." The article on perspective drawing with a home-made trammel is continued.

The *Architectural Record* has this month several interesting articles. "Drawing, Designing, and Thinking," by William R. Ware, is thoughtful and thought-inducing. "The Architecture of the Pacific North-West," by Robert C. Sweatt, illustrates the improvement in architectural design that is becoming manifest in "the richest section of the United States." "The Work of William Appleton Potter," by Montgomery Schuyler, is an account of the half-century of work of the George Edmund Street of the United States, with whose work both in its Gothicism and its ecclesiastical character Mr. Potter's designs have much in sympathy. Like Street, Mr. Potter passed through various phases of influence, Venetian, French, English Gothic and the Richardsonian manner all swayed his style. "Some Impressions of Modern German Architecture," by Alfred Hoyt Granger, is an appreciation of the remarkable movement that has taken place in the architecture of Central Europe during the last twenty years, the outcome of a well-proved development of the "new art" principle that in the hands of its best exponents has eliminated from architectural design everything unnecessary, depending only on simplicity and proportion. "Some Sixteenth and Seventeenth Century Parisian Mansions," by Frederic Lees, brings before us some of the charming domestic buildings of old Paris.

Berliner Architekturwelt gives us a description and illustrations of some of the exhibits of the Home Exhibition held at the Berlin Zoological Gardens this year, excellent examples, principally of internal treatment, of modern German simplicity and good proportion in architectural design. "Marinehaus," by Otto Leisheim, a block of buildings at the corner of Brandenburgh Ufer and am Köllnischen Park, Berlin, is a combination of concert hall and flats. Several other groups of flat-buildings are illustrated, so that we have quite a review of modern German architectural work in this direction. It is remarkable how much play of light and shade is obtained in these purely commercial enterprises by judicious use of bays, oriels, recessed loggias, balconies and studied roof treatment, although the buildings are brought strictly up to the street line on the ground floor.

Der Profanbau devotes itself entirely to the new baths erected at Breslau by private enterprise at a cost of over 66,000*l.*, from the design of Professor W. Werdelmann, a quite remarkable example of bath design, containing many features that one would hardly deem possible in a building that must be made to pay its way.

Deutsche Bauzeitung illustrates a charming open-air bandstand or "music-temple" recently erected as an adjunct to the town theatre of Dortmund, from the designs of Professor Martin Dülfer. Some picturesque buildings of the Royal Bavarian Ministry of Commerce, chiefly station-masters' houses and post-offices, are also illustrated.

Digitized by Google

Der Architekt illustrates the competition design of Heinrich Ried for new buildings of the War Office "am Hof" at Vienna, with a nicely reproduced water-colour of the present buildings. A design for a detached private house in Vienna is delightful in its breadth, but one wonders how the rooms are lighted.

COMPETITIONS.

THE Newburn District Council have received sixteen sets of plans for a new Council chamber, offices and caretaker's house. The competition was limited to architects practising in Newcastle-on-Tyne and Northumberland. Mr. R. J. Leeson is acting as assessor.

The Lytham Town Council have been considering the question of reconstructing or adapting the baths and assembly rooms for a public hall. They have decided to invite sketch plans and estimates for (1) the reconstruction only of the baths and assembly rooms; (2) adapting the existing buildings for improved baths and public hall from the following invited architects:—Messrs. S. Thomas, Ansdell; A. S. Gledhill, Lytham; Haywood & Harrison, Lytham; and Muirhead & Co., Manchester. Plans have to be in by September 15.

Correspondence.

[*The Editor will not be responsible for the opinions expressed by Correspondents.*]

London University Appointments Board.

SIR,—It may be of interest to many of your readers to know that an Appointments Board has been constituted by the University of London. The terms of reference to the Board are "to assist graduates and students of the University in obtaining appointments, and to co-ordinate and supplement the work done by the schools and institutions of the University with this object." I am directed by the Board to express their hope that, through the medium of the Press, the objects of the Board may be brought to the notice of graduates as well as of those who are able and willing to assist in furthering the work of the Board, the aim of which is to encourage the selection of university men for all posts in the work of which the possession of a university training on scientific methods is an advantage. They wish to assist graduates to find employment, and to assist employers to find in the university ranks suitable men for vacancies.

It would assist the Board if, whenever your readers know of any vacant appointments suitable for university men, they would communicate with the Secretary of the Board, so that he may put forward selected candidates. In this way the work of the Board as an employment exchange would be greatly helped.—Yours faithfully,

HENRY A. MIERS, Principal.

University of London, South Kensington, S.W.

The People's Budget.

SIR,—It was with much interest I read the Auctioneers' Memorial, published in your issue of the 20th ult. It is an excellent and carefully drafted document which must have met with general approval, as it contained practically all that was necessary from an auctioneer's point of view, but as it seemed rather to consider the interest of the land owner it was hardly likely to meet the approval of Mr. Lloyd George. Had the auctioneers pointed out the loss and suffering sustained by the working-classes, more sympathetic consideration would have been obtained.

Of late years a number of auctioneers have speculated in building land, acting as their own architects and their own builders, giving employment to a large number of workmen. Surely some of these gentlemen could have pointed out to the Chancellor what damage the Budget was doing to all workmen connected with the building trade.

The working-classes are the predominating Parliamentary voters, who are awaking to the fact they have been played with long enough. To obtain their votes, at one time they are promised three acres and a cow, and at another ample work and a big loaf, but at no time has there been such crowds seeking for work and begging for bread.

The workmen are not the only sufferers, as many able architects, surveyors and builders have to reduce their staff for lack of work through the disinclination of men of capital and enterprise to consider any building project until the present Budget is dead and buried, and public confidence restored.—I am Sir, yours faithfully,

FREDK. NESBITT KEMP.

14 Featherstone Buildings, W.C.: Sept. 6, 1909.

GENERAL.

Maiden Castle, near Dorchester, the greatest of the prehistoric camps of England, has now been transferred to the guardianship of the Office of Works.

The Canterbury City Council have rejected a resolution that the Dean and Chapter be asked to alter the time of the cathedral clock to Greenwich time. The time is over four minutes faster than that of Greenwich.

Mr. Lloyd George, M.P., has stated that he cannot see his way to granting the request of the National Trust for Places of Historic Interest or Natural Beauty that land conveyed by gift or purchase, and dedicated to the use of the public and held by the National Trust or any such public body, should be exempt from stamp duty under Clause 53, sub-section 1, of the Finance Bill. He added that in exceptional cases of established hardship power already exists for granting relief.

The Blackburn Town Council last week adopted a formal resolution giving power to the Corporation to borrow 80,000*l.* for a period of sixty years to build and furnish public buildings on Blakey Moor.

The Public Health Committee of Dundee Town Council have agreed to instal a system of electric lighting into King's Cross Hospital at a cost of between 250*l.* and 260*l.*

The Programme of weekly lectures for the session 1909-10 in connection with the Newcastle Literary and Philosophical Society has been issued. It contains the following in the miscellaneous course:—September 27.—Professor W. M. Flinders Petrie, D.C.L., LL.D., F.R.S., "Discoveries at Memphis and Thebes." October 11.—F. W. Dendy, "The Making of Newcastle." November 1.—Herbert Thompson, M.A., LL.M., "Painting in England from Holbein to Hogarth." January 31.—George Hubbard, F.S.A., F.R.I.B.A., "Dew Ponds." February 14.—S. C. Kaines-Smith, M.A., "The Triumph of Athena: Athens and the Panathenaea in the time of Pericles." February 28.—Vaughan Cornish, D.Sc., "The Panama Canal." Mr. A. Hamilton Thompson will give a series on "Renaissance and Modern Architecture."

The Report of the departmental committee of the Home Office, appointed on March 22 "to consider and report what place would be the most suitable, having regard to convenience and economy, for transacting the Quarter Sessions business of the County of London; and what, if any, improvement could be made in the arrangements for the trial of criminal cases and the hearing of appeals," was issued on Saturday as a Parliamentary paper. The committee are strongly in favour of the purchase of a central site—i.e., in the area bounded by Holborn, Farringdon Street, the Strand and Shaftesbury Avenue—and a new Sessions House erected thereon. It is said the existing Sessions House at Newington is insufficient to accommodate all the business of the Sessions, and cannot be rendered suitable by means of enlargement or alteration unless at a grave sacrifice of convenience.

The Council of the Royal Society of Arts hold a sum of 400*l.*, the balance of the subscriptions to the Owen Jones Memorial Fund, presented to them in 1876, on condition that the interest be spent in prizes to "Students of Schools of Art who, in annual competition, produce the best designs for household furniture, carpets, wall-papers and hangings, damasks, chintzes, &c., regulated by the principles laid down by Owen Jones." Competitions, under the terms of this Trust, have been held annually since 1878. The next award will be made in 1910, when six prizes are offered, each to consist of a copy of "The Leading Principles in Composition of Ornament of every Period," from the "Grammar of Ornament," by Owen Jones, and the Society's bronze medal. The designs must be submitted by April 1, 1910.

The Cowley Fathers have granted the Vicar of Worksop the use of the Priory Gatehouse for church and parochial purposes. Its restoration at a cost of 500*l.* is now under consideration. The Gatehouse is of great archæological interest.

The Old Tramway Station in Regent Road, Bootle, is to be adapted into a roller skating rink. The alterations are expected to cost between 500*l.* and 700*l.*

FORTHCOMING EVENTS.

Thursday, September 23.

Institute of Sanitary Engineers: Opening Sessional Meeting a Caxton Hall, Westminster, S.W.

Saturday, September 25.

Institution of County and Municipal Engineers: Eastern Distric Meeting at Lincoln.

Monday, September 27.

Architectural Association: School of Architecture, Winter Term begins.

Iron and Steel Institute: Autumn Meeting in London September 27 to October 1.

Monday, October 4.

Royal Academy: Course of six Lectures on "Chemistry" by Professor A. H. Church, D.Sc., M.A., F.R.S., opens. Subject: "Paper, Canvas, Panel, and other grounds."

Friday, October 8.

Architectural Association: Annual General Meeting. President's Address and Distribution of Prizes.

COMPETITION DRAWINGS FOR EXTENSION OF GRIMSBY TOWN HALL.

THIS is one of the most unsatisfactory competitions that has been promoted for some time, even more so than Stoke-upon-Trent, for in this case not only is the sum allowed insufficient for what is demanded, but the competitors were hampered by a suggested plan, sent out with the instructions, which is virtually the idea of Sir GEORGE DOUGHTY, M.P. for the borough and prime mover in the scheme for the extension of Grimsby's present town hall. It has been made evident by the result of the competition that the suggested plan, with all its faults—and they are many—has ruled the situation, and that no design however good stood any chance of success if it departed materially from the suggested plan. The estimates of cost of the competitors have clearly been made very largely on the good old competition method of cubing at 1*d.* to see what price can be allowed. Perhaps too much credit has been given to the fact that Grimsby is a port, but it takes a lot of water carriage to bring down the price of a town hall to 4*d.* a foot cube.

The result of the unsatisfactory data of the competition is that very few architects of ability have entered, and there is therefore an exceptional display of ambitious incompetence wrestling with impossible conditions and producing futile conceptions. Those architects who have taken part in the competition have been wrecked between the Scylla of an impossible suggested plan and the Charybdis of too great expense.

The first premiated design by Messrs. EADE, JOHNS & BROWNE follows very closely on the sketch plan supplied to competitors with the instructions. The present assembly room is "extended," that is to say, it has had its front wall and two end walls removed, and the remaining wall considerably altered, thickened, and raised. Then in place of the old assembly room is built a large assembly hall 93 feet by 60 feet, with a segmental ceiling, the height to the springing being 32 feet and to the crown 42 feet. A good platform is provided at one end of the hall and a large gallery runs round the better part of three sides. The entrance is at the west end, where a crush hall, principal staircase, councillors' retiring room and committee room fill out the building in this direction. At the east end of the assembly hall is a green room with retiring rooms for ladies and gentlemen opening off it, and above these are the raised seats for the orchestra. The assembly hall with its adjuncts east and west forms a block 184 feet long by 65 feet deep, and is admirably planned for its purpose. The present stair to the assembly room is retained as a secondary stair to the new large hall. On the ground floor of the front block is located the Town Clerk's department with three committee rooms and public and private parlour for the Mayor. There is a central corridor 10 feet wide, which, like the corridors generally in the suggested plan of Sir GEORGE DOUGHTY, appears to us very inadequately lighted.

At the rear of the front block on the first floor the present banqueting room and its adjuncts are retained, as is also the council chamber. In front of the council chamber is a new corridor and committee room, the walls of which are supported in mid-air over the county court below. The new corridor between the council chamber and committee room leads to the grand staircase lobby of the smaller assembly hall, which is 61 feet by 61 feet. On the ground floor the Borough Treasurer's department and that of the Borough Engineer are placed under the smaller assembly hall, the Registrar's court below the council chamber, the county court, as already mentioned, below the large committee room, corridor, and lavatory, and the enclosing walls of these, whilst the police court is neatly fitted in between the old police station and the Registrar's court. Under the banqueting room is placed the Medical Officer of Health's department, and by a strange irony that official's private office is lighted by two windows looking into an area which is 7 feet wide in front of one and 9 feet wide in front of the other.

As in the suggested plan the public entrance to the smaller assembly hall is common also to the three courts, whilst the Borough Treasurer and the Borough Engineer can only interview the Town Clerk by going out into the street, traversing the legal portion of the building, or going upstairs, along a corridor and down again.

The plan, granting the necessity of following closely the suggested plan, is excellent, but the suggested plan has many grievous faults, and these, though minimised, are reflected in the accepted design. It is fortunate that Grimsby is not very far from Middlesbrough, as the amount of steelwork that will be required to carry walls over voids will be quite exceptional. The cost of shoring will also be very great, and we doubt very much if the work can be carried out for the sum estimated. The two assembly halls with the offices under are cubed at 5*d.*, and the rest of the new building at 6*d.* From the amount thus obtained, 2,600*l.* is deducted for value of old walls and foundations and old material re-used.

The elevations include a lofty tower, and are shown to be carried out in stone with a considerable amount of costly work of good modern municipal Renaissance character if not very original.

The second premiated design, by Messrs. WITHERS & MEREDITH, though following generally the arrangement of the suggested plan, does so very much less closely than the first premiated, and we may also say very much less ably in many respects. The Law Courts department is rather better than in the winner's plan, with the exception of one quaint eccentricity—the entrances to the galleries of the three courts are through the cloak-rooms of the

Digitized by Google

ladies and gentlemen using the small assembly hall, and the gallery of the county court forms a means of communication with those of the police court and Registrar's court, so that when the unwashed and unemployed of Grimsby are tired of listening to a civil action they can find relief by attending a criminal case. The offices in general are well lighted, and there is not so much dark corridor as in the first premiated design, but to get these advantages the large assembly hall is shorn of much of the attractiveness of the selected design. The elevation is somewhat similar to that of the first premiated, with a lofty tower, which, however, does not grow naturally out of the substructure, but seems to shoot up through the roof rocket-like.

The design placed third by the assessor is by Messrs. RIGBY, OLIVER & PHIPPS. It follows the suggested plan even more closely than either of those placed before it, and so retains more of the original faults, such as a Town Clerk's general office 32 feet 6 inches deep lighted from an area or well hole 9 feet 6 inches wide.

The elevation again has the big tower, but there is a general unrest due to defective composition and multiplicity of incoherent detail that quite precludes any satisfactory result.

Mr. STEWART M. MOULD has wisely preserved intact what of the old buildings he has used, the banqueting room, the assembly room, and the council chamber with the rooms under, and has produced a plan that to our mind is far superior to any of those placed by the assessor. The exterior is dignified and broad in treatment, but cubing at 4*d*. and 4½*d*. would hardly cover the cost.

Messrs. RUSSELL & COOPER have submitted two designs. In the one they retain the old banqueting room, council chamber and assembly hall, and propose a new large assembly hall at a skew angle to the lines of the main and existing buildings. A good plan is the result, and there is no doubt that for the accommodation asked some such scheme as this is the best solution of the problem, but the limit of cost is prohibitive. Messrs. RUSSELL & COOPER cube their large hall at 5*d*. and the remainder of the buildings at 6*d*., with 2*d*. for the old buildings that are re-used with alterations. The second plan sent in by Messrs. RUSSELL & COOPER is unworthy of their reputation, though better than many others in the competition. In this design they show a tower, but in the first mentioned there is none, and a dignified and almost too severe composition is proposed.

Professor BERESFORD PITE, like Messrs. RUSSELL & COOPER, retains the banqueting room, council chamber and assembly room, and proposes a new large assembly hall in a similar position and on similar lines. The result is a good plan, though not without faults of detail. The exterior is a very quaint conglomeration of picturesque bits from seventeenth-century Germany.

Mr. G. WASHINGTON BROWNE has kept the old banqueting room and assembly room, but swept away the present council chamber and provided a new one, as well as a new large assembly hall. In this case, by utilising the site of the old council chamber, the new large hall is kept rectangular with the remainder of the building. The plan is on the whole good, though there are such faults as an enquiry office for the town clerk with no light. Mr. BROWNE cubes at various figures, from 6*d*. to 9*d*., so that if his calculations are correct he has produced one of the most economical plans submitted in the competition.

Mr. E. MONTAGUE THOMAS has followed too closely the suggested plan to rank with either the selected design or the best of those that depart from the ideas of Sir GEORGE DOUGHTY, and Messrs. LEEMING & LEEMING are in the same boat. In their external treatment Messrs. LEEMING seem to have tried to make their building look as little like a town hall as possible by using a two-storeyed arrangement of comparatively small windows for their large assembly hall. The result is a design that would be admirable for a block of municipal offices, but not expressive of the functions of the town hall that Grimsby—or Sir GEORGE DOUGHTY—wants.

BELFAST AND ITS ABATTOIR.

THE plan prepared apparently by the City Surveyor and now put forward by the City Council of Belfast for the proposed new abattoir is subjected to severe criticism by Mr. JAS. J. PHILLIPS, an architect practising in that city, and his strictures appear to us to be quite well founded. In the planning of an abattoir the most important of all considerations is the preservation of the purity and quality of the meat. It is only the attainment of this desideratum that justifies the existence of an abattoir at all. If it is not attained it would be better, as was done almost universally half a century ago, to let each vendor of meat kill his own animals one at a time as he wanted them, and to be a butcher in reality rather than as he is at present a purveyor of meat. With somewhat more careful attention to cleanliness and sanitary conditions than too often prevailed in the old days, the slaughtering of beasts singly has much to recommend it as superior to the modern abattoir system of wholesale hecatombs, as regards both the freedom from taint of the meat and the avoidance of unnecessary cruelty.

The avoidance of cruelty is an essential in abattoirs only slightly less important than the maintenance of the purity of the dead meat, for it is undoubtedly the fact that pain, whether physical or mental, inflicted upon an animal about to be slaughtered is detrimental to the quality of the meat. So that apart from all humane considerations the infliction of unnecessary pain or even discomfort upon the beasts is bad business. When an animal is about to be killed for food it must necessarily be brought into a strange environment and every care should therefore be taken so to arrange an abattoir as to prevent any undue cause of alarm. Strange noises, strange sights, and especially strange smells must be as far as possible avoided. Above all the sounds of killing, the sight of carcases, the smell of blood must be kept from the cognisance of the animal whose time has not yet come.

Other desiderata of a well-planned abattoir are easy access for butchers or purveyors of meat, healthful conditions for slaughtermen, drovers and dressers, easy inspection and supervision by veterinary surgeons and other officials controlling the establishment.

How are these desiderata of a well-planned abattoir met in the Belfast plan? Admittedly the site provided is too small for the purpose, and the City Council has been warned of this defect by a report from the City Surveyor and by its condemnation by Dr. H. W. BAILIE, the Superintending Medical Officer of Health; by Dr. CLIBBORN, of the Local Government Board; and by Dr. MCCAW, President of the Ulster Medical Society. This defect of the site might have been palliated by the adoption of a two-storey abattoir, as has been done at Dresden, Frankfort-on-Main, Gorlitz, Neisse in Germany, and in the British examples at Glasgow, Leeds, and Birmingham. The city fathers of Belfast seem, however, to have made up their minds that they will have a one-storey arrangement, room or no room.

How is the freedom from taint of the killed meat ensured? The hanging rooms are in the middle of the site, surrounded by the slaughter-halls, and these by the lairages and pens, thus enclosing the meat-hanging rooms on all sides with sources of taint and infection. This disposition alone is amply sufficient to condemn the plan now put forward.

Cruelty to animals seems to have been one of the objects sought rather than avoided in the arrangement of the plan. A considerable proportion of the lairages are placed below the arches of an overhead street with tramcars and other traffic thundering above the poor beasts in their strange quarters, so that they may be as much frightened as possible. The main entrance for cattle is at the extreme end of the site, so that they may have to be driven right round the whole establishment before they reach their lairage or pens, and on their journey they pass the stables and the byre and slaughter-house for diseased cattle. Thus there is every opportunity for the animals

Digitized by Google

CONCRETE RESIDENCE, LOS ANGELES.—GARDEN FRONT.

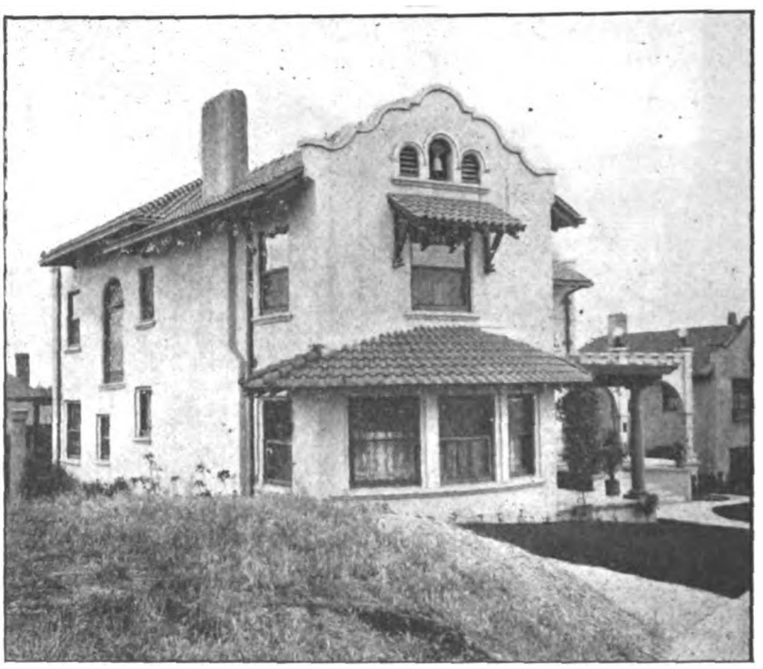
to become frenzied almost beyond control, which is not only dangerous to those engaged, but as we have already pointed out, highly detrimental to the quality of the meat. Then the swillings of the slaughter-pens are in the plans shown to go to an open drain in the passage between the lairages and the slaughter-halls, so that the smell of the swillings, charged with reeking hot blood and vestiges of slaughter, meets the nostrils of the terrified beast as he is drawn across the passage. It is needless to point out how much such a condition of affairs adds to the danger of slaughtermen and hence to the harshness and even brutality with which they are likely to treat the beasts that come under their hands. All of which is objectionable not only from the point of view of morality and humanity but of business. Bad treatment of animals means inferior quality of meat. Verily if this abattoir is carried out as proposed Belfast will be a city to be avoided by all tourists and visitors who are not obliged to go there and who have some regard for their digestion.

There are other considerations, possibly less important than those we have placed as the first elements of a properly planned abattoir, but still of vital importance to anything like a decent plan. The arrangements for the reception of animals sent in by butchers for slaughtering are of the crudest, and quite a numerous staff will be needed to assist the drovers, who must leave their charge in the care of someone whilst they do their necessary business in the offices. The defective planning of the access to the lairages and pens that we have already noticed in connection with the question of cruelty is, of course, a further violation of the principle of convenience for butchers and their drovers.

A subsidiary entrance for beasts from the cattle market adds to the general confusion. These beasts, if the accommodation has been rightly proportioned, might reach their lairages without coming into collision with those entering from the main entrance; but access to the sheep pens and piggeries is impossible without encountering the streams of oxen, unless it is intended that the sheep and pigs should be driven by the ways used by butchers' carts taking away meat. Thus the convenience of butchers and drovers appears to have been badly considered. The provision of sanitary accommodation for workers is about as defective as could possibly be arranged—at one end of the site, so as to be far from those engaged at the other, and close to the to the meat-testing department, whose efficiency it can scarcely enhance. The veterinarian's offices are next the principal entrance, presumably with the view of allowing him ready inspection of animals entering there, but they are as far as possible from the entrance from the cattle market and quite secluded from the work of the abattoir, so that there is no chance of overlooking what is going on in the slaughter-houses or the hanging rooms. In fact, the administrative offices seem to be so located as to present the maximum of difficulty for supervision. There might be a bull-fight, or a murder, or the grossest cruelty going on and the chief officials might be in blissful ignorance.

It cannot be consideration of cost that is leading the City Council of Belfast into approval of so defective a plan, as they propose to spend at least 32,000*l*. on the first section of an abattoir for a town of 350,000 inhabitants; whereas Leeds has provided itself with a complete model abattoir to serve a population of 417,000 at a cost of 25,400*l*.

Thus it will be seen that Belfast's City Council is committing itself to an utterly unsatisfactory plan, and one that, if carried out as proposed, will make Belfast's abattoir a laughing-stock and by-word to the world.



NOTES AND COMMENTS.

SNAP-SHOT drawing, on which, as reported in our last week's issue, Mr. T. R. ABLETT, founder and art director of the Royal Drawing Society, lectured at the Shepherd's Bush Exhibition as useful "for engineers and architects," appears to us to be valuable as a correction of the tendency that the everyday work of geometrical drawing of plan, section and elevation has to cramp the architect's, and especially the young architect's, ability to realise the aspect in three dimensions of what he draws.

THE work of the Royal Drawing Society is primarily to foster and encourage the natural instinct of children to draw, not necessarily for the purpose of increasing the number of artists, but for the development of the faculties of observation and imagination. These faculties are obviously of high importance to the architect, and without them he cannot be really what he professes and aims to be, an architect and an artist. Hence anything that helps to increase his power of observation and imagination is valuable.

SNAP-SHOT drawing is practised in the method of the Royal Drawing Society by the presentment of some object or group of objects for a limited time to the eyes of the scholars. Then the actual vision being removed, the snap-shottists draw as much as they can remember in a definite time. Thus that particular form of memory which is known as visualisation is exercised, and concurrently the observation and selection of salient points in the subject snap-shotted. In practising snap-shot drawing it is absolutely essential that the draughtsman should re-

Digitized by Google

CONCRETE RESIDENCE, LOS ANGELES.—FRONT VIEW, NORTH END.

produce from the solid and not from a drawing of the object by himself or someone else. The practice of snap-shot drawing is likely to assist the young architectural student in designing buildings, as he should do, in perspective, to realise his conception of a building or part of a building in three dimensions, that is, in the solid.

WHETHER it is worth while for those of the public who are about to erect buildings in which cost is a consideration to adopt fire-resisting construction is an important question when a building has to be made to pay its way. Hence the carefully considered article by Mr. J. P. H. PERRY in *The Engineering Magazine* on the comparative cost of reinforced concrete and ordinary construction in mill buildings is both interesting and useful. Although Mr. PERRY's figures are based on American practice and experience, the conclusion is valuable at which he arrives, that a concrete building will save each year 2 per cent. over an ordinary mill building whose original cost was 10 per cent. lower.

THE State Board of Health of Maine, U.S.A., has issued a bulletin in which is recorded the result of experiments in the Agricultural Experiment Station at Storrs, Conn., on the number and nature of the bacteria that the common house-fly carries with him. Typhoid, tuberculous, and other baneful bacteria were found in large numbers, and the house-fly, like the mosquito, stands convicted of being an active disseminator of disease. Filth is necessary both for the propagation and the existence of the house-fly, and therefore the need for cleanliness is insistent. But as it is practically impossible to eliminate from the outside environment of buildings all opportunity for the house-fly to breed, door-screens and window-screens should be extensively used to exclude flies from our houses.

OLD SARUM is now in process of being explored by excavation under the auspices of the Society of Antiquaries, with the sympathies of the Wiltshire Archæological Society. The foundations of the Norman buildings are to be first investigated, with some expectation that they may reveal traces of an earlier period, possibly even of the Bronze Age. Any objects of interest will first be exhibited on the site and afterwards committed to the care of the Dean and Chapter of Salisbury. Amongst the first of these objects are three silver pennies of Edwardian date, which have already been discovered.

A CONCRETE RESIDENCE IN LOS ANGELES.

THE progress that is being made in the use of concrete is a topic of the greatest interest in the building and industrial world. It is not so very long ago that America heard of its first reinforced concrete construction. Then it caused wonder and astonishment because of the results accomplished, but notwithstanding that that was not too long ago to be still in the public mind, the people have come to expect anything and everything of this method of construction.

True, there were mishaps and disappointments when builders attempted to rear structures of reinforced concrete when that material was new to them. That in itself is the reason for it—the fact that it was new to them; but those accidents and disappointments only served to make more certain the future of reinforced concrete. Such incidents only served to demonstrate that the utmost care and precaution must be taken not only with concrete, but with all classes of building material.

While it is but a step from the early days of reinforced concrete to the present time, the varied and numerous uses to which the material is now put tells its own story of the favour with which it is regarded and the success which has accompanied its use.

What reinforced concrete will do in home construction is to be seen on Ocean View Avenue, in the residence of F. A. Urban. While there are now many houses in Los Angeles of concrete structure, the dwelling of Mr. Urban is the first one to be entirely built of reinforced concrete. It cost about $26,000, and is designed in the so-called "Mission style."

The home contains two storeys and a basement. It is planned so that every inch of space is available and every room is an outside one. The walls and foundations are wonderful examples of solidity and strength, the builders declaring that none of the elements could wear or shake them.

All footings, walls, piers and columns were built of concrete made as follows:—Sharp clean sand, two parts; gravel, fine, under 1 inch in size, three parts; and cement, one part; turned three times dry to well mix, then wetted and turned twice, and immediately put in the forms prepared in the ordinary way to receive same and tamped solidly, so that no voids existed. The foundations are 13 feet below the level of the land, and are 3 feet wide at the base. The walls to the first-floor level are 18 inches thick, while above that they are 12 inches.

The floors of porch and side porch were made of concrete 3 inches thick, and on top of same was placed a mortar mixture—two parts screened sand and one part cement, tinted as desired, trowelled off smooth, and marked off in squares 12 inches by 12 inches, the floor having a slight fall outward.

Digitized by Google

CONCRETE RESIDENCE, LOS ANGELES.—REAR VIEW.

The concrete steps were finished in same manner, with treads 14 inches wide. All floors in basement are of cement. All walls were reinforced with ½-inch steel rods, and the two walls above bay-window openings were further reinforced with three 1-inch steel rods each; the walls above 5 feet, windows and doors were reinforced with three ½-inch steel rods to each opening. The chimneys are all of concrete. On the first floor are six fine rooms, all very large and finished in mahoganised white cedar. The reception hall is 18 feet by 30 feet, and the reception room 16 feet by 27 feet. The den is 14 feet by 16 feet, and the dining-room adjoining 17 feet by 23 feet. There is a little breakfast-room 10 feet by 12 feet, and a large kitchen.

There are six rooms on the second floor, finished in white enamel, the walls being tastefully decorated. The rooms are well ventilated, and heated by an Equator steel furnace and Humphrey automatic water-heater, the latter furnishing hot water for the entire house. The door locks and trimmings are of solid brass. All the rooms have coved ceilings, with the exception of the breakfast-room and den, which have mahogany beam ceilings. In the bedrooms are complete equipments, including lavatories with hot and cold water.

The place is fitted throughout with electric lighting, with gas as an auxiliary if required, the fitments being highly artistic, and where possible of cut glass.

Six hundred and seventy-five barrels of cement and 5,000 lb. of steel reinforcement and hundreds of eastern tiles of special design were necessary in the construction of this house. All work was done by day labour, the job taking seven and a half months to complete, every part being made perfect as far as possible, and every convenience known to modern house construction has been installed, including even the Mission bells to complete the effect.

CHURCH AND STATE.

By VIATOR.

IT is perhaps unnecessary to remark that this article is in no way political, for it would not under such circumstances be suitable for a professional magazine of the character of *The Architect*. The object is to discuss the preference of one style of architecture over another for buildings devoted to the purposes of Church and State, and to discover if possible the reasons underlying such preference.

We would not wish to be dogmatic—a quality that has been aptly described as "matured puppyism"—in the following research; modesty is the writer's guide, and intelligent receptivity should be accorded by the reader.

In earlier days, when a nation practised its own style and when those of other countries were generally unknown outside their respective territories, buildings of all classes were perforce designed in the one style, regardless of its inherent fitness from the critic's standpoint. We must walk warily here if we are to avoid a pitfall, for what is to be understood by inherent fitness? If a nation exhibits its own type of art—be it severe, bulbous, elegant, lavish, dignified, or otherwise—surely (some would urge) that nation thus expresses its attitude towards the passing hour, passing events and towards history in the making, and so best realises posterity's claims upon it. This argument is of little worth, if any; what it amounts to is that one nation is inherently (or temporarily, perhaps) better adapted for the display of one particular phase of man's complex temperament, such phase being best expressed in one particular class of building. This may be made clearer possibly by what follows.

The attitude of the ancient Greeks towards religion, art, dialectic and rhetoric is worthy of consideration. Their Pantheon was peopled by a mythological crew of demonic divinities, who were actuated by human passions and were willing, in consideration of bribes, to divert the otherwise proposed course of events. Originally these divinities merely symbolised various forces and propensities of Nature, but after a lapse of time they received an accretion of individual and divine power. The Greeks treated their gods and goddesses with a cool aloofness of passion that has in it an amusing element; there was no religious ardour such as is now understood, and characters like Socrates were not numerous enough to affect the general racial characteristics, the latter including many interesting and even fine qualities, though amongst these we do not find religiosity. This being so, what wonder is it that the Classic temples, however much we may admire them as works of art, do not appeal to our religious sense? They leave us sensuously cold and uninspired and conscious of the insincere religion that accompanied their production. Insincere! That is a most suitable adjective to use, for as it well defines the Grecian attitude towards ethical matters, so was the opposite quality—sincerity—the potent factor in all that concerned their art; and it is directly due to this unaffected bias towards the fine arts that the Greeks produced buildings which cause beholders to forget purpose and fitness in the rapt artistic admiration engendered by the other essential qualities of good design.

Examining further we may note the Athenian love for academic debates, their rigorous adhesion to and devotion for good laws, their virile belief in the *mens sano in corpore sano*; and thus we learn to realise the fact that in these matters their art aided the sense of fitness instead of opposing it. For though the academic qualities of their religious buildings served to express in the main their own attitude towards religion, we hold that such is not the natural or rational attitude. On the other hand, the dignified sedateness and the restrained beauty of their secular public buildings were more worthily and suitably decked in Classic garb than they would have been in any other known to the children of men, Renaissance alone excepted.

Though Roman as compared with Grecian art was somewhat debased, yet it possessed the same elemental features and a similar aspect in regard to religion up to the days of Constantine the Great. But the Romans developed a love of luxury unknown to the Athenians in their palmy days, and this taste acted adversely respecting the architectural design of many of their public buildings, though bathing establishments and places of entertainment would benefit;

Digitized by Google

and in this connection the Pantheon at Rome, regarded as a hall attached to public baths, has indisputable claim to admiration, whilst viewed as a temple it is unsatisfactory.

Following upon those remarks that child of Classic architecture known under the name of Renaissance is similarly less fitted for the expression of religious ideals than are those styles which bear the stamp of indigenous religious fervour. And it is to be observed generally that people are more soulfully impressed in places of worship designed in one of the Gothic styles, even if at times they are more intellectually moved by Renaissance churches.

Before, however, adverting to Gothic art, a few remarks may be accorded to early Christian and some other styles, and to the position they hold in regard to inherent suitability for Church or State architecture. Respecting early Christian populations there cannot be two opinions as to the sincerity of their religious tenets, a sincerity not necessarily reflected in their ecclesiastical buildings for reasons now to be stated. Where persecution of the believers was not actively exercised, it was nearly always to be anticipated; consequently religious enthusiasm expended itself in acts of devotion and martyrdom, though it was at the same time recognised as impolitic and unchristian to invite the imposition of that thorny crown by any show of luxury such as might provide a lever wherewith the persecutors could raise a specious case against the followers of the new faith. Not indeed that there was much chance of being luxurious, as the early Christians were for the most part poorly endowed with the world's goods, and were thus deprived of the means of gratifying a natural desire to honour their Master by the presentation of choice gifts. Policy and poverty thus combined to prevent the early Christian churches from being places of grandeur. As a result the buildings erected were mere *aulæ* or *basilicæ*, the plan being that of the old heathen Hall of Justice and not infrequently structurally decorated with portions of old heathen disused temples; of necessity the result was nearly as cold and formal as Classic art itself, and it could in no way interpret the mysticism attaching to Christian tenets.

But (it may be remarked) Oriental art is not cold and formal; Chinese, Japanese, Byzantine, Indian—these are not cold and formal, nor actuated in regard to expressing religious sentiment by any such restrictions as just detailed. To dispose of the first-named it is well-known that the Celestials have been conservative in art as in religion and everything else from the early days of their very ancient empire; any reforms and progress observable in their territories have been forced upon them by external pressure. Though a very ancient civilisation—or perhaps because of its antiquity—it is one that other nations regard as childish in many respects; with childhood, crude ideas as to form and colour go hand in hand. The religion of Confucius is one apart from all other known creeds and is perhaps justly given effect to by the fantastic designs of Chinese art. In fact, this nation is adapted (and possibly better adapted than others) to express garden architecture and similar work, but it cannot do justice to Church or State buildings.

Any nation also whose taste for luxurious display pervades all its actions at home and abroad, a nation that regards the Ruling Power as supremely sensuous and the future state of existence as a life of voluptuous pleasures, any such nation is but ill-adapted to express religious or State architecture in a manner that would adequately realise their respective claims; and consequently, under the ban of unsuitability, we must include Oriental styles generally.

Byzantine architecture gives evidence of the co-operation of true religious feeling and expression, though for the full development of this we must seek the Gothic styles. In the eastern empire of Constantine buildings were erected whose planning was no less serviceable for the proper exercise of worship than that of the early Christian buildings, and whose architectural treatment, unshackled by considerations either of prudent seclusion or of economy, yet evinced an artistic avoidance of exuberance combined with a justifiable use of colour and of structural design.

It is, however, only when the period of the later Romanesque work is reached that a distinctly expressed ecclesiasticism is observable. Perhaps the main factor responsible for this is the religious ardour arising after the close of the tenth century of our era, when people were relieved from the fear that the world would end with the close of the year 1000. The bar safely crossed, the nations put out to sea full of hope and thankfulness, and being more simple-minded and direct than those of to-day they were not afraid to express their love and gratitude in buildings devoted to their religious worship.

It must be evident that where the idea of a God is of an exalted Being inhabiting space and far removed from the pettinesses of mortals, this will best find expression where no cramped effects are to be seen; and as the curious notion has ever been prevalent that heaven is above us, not around us, this would again be best expressed by a lofty building.

But there is another point to bear in mind as probably influencing the adoption of loftier church interiors, and this is the introduction of the organ fairly contemporaneously with the advent of the eleventh century. To give due effect to the tones of this majestic instrument a spacious building is required.

At the same time also (or perhaps somewhat earlier) there arose from whatsoever cause a general disuse of Autolycan trifles from ancient heathen edifices such as had formerly been introduced mosaic-wise into Christian churches. A certain "feeling" of Classicism in the ornament was to be expected, but progressively this gave place to other forms, not intrinsically better by any means, but as having no resemblance to what had preceded they kept the mind of the observer free from any suggestions of heathen work. Anything in the nature of affectation in this matter of suitable mouldings and ornament is to be deprecated; the bowtell, dog tooth, cat's head, roll moulding, diaper, &c., are no more expressive of religious feeling than are the echinus, scotia, egg-and-dart, honeysuckle or acanthus. Where the difference arises is in the workmanship, mediæval art showing an individuality, a freedom from undue restraint, a lack of cold formality, altogether opposed to the practice of Classic art.

The desire to obtain increased proportionate height prepared the way for the use of the pointed arch; and here, once again, is apparent an added interpretation of religious ideals. With the semicircular arch the eye is held within a confined space, travelling from one springing point to the other almost unconsciously; with the pointed arch the effect is just the reverse, the eye tending to continue the course of flight upwards. Quite unconscious interpretation we may believe this use of the pointed arch to be, but none the less effective. The idea that pointed architecture had its origin either in leafy avenues or in intertwining round arches may be set aside as being more plausible than probable.

A reference was made earlier to the mysticism attaching to Christian tenets; this may be contrasted with what may be termed the "mystery" connected with some of the more remote faiths wherein the prevalent idea was that the gloom of the temple interior should be in direct ratio to its sanctity. This effect of gloom and mystery was obtained by two methods, if not three; the ancient temple consisted of a congeries of rooms progressively narrower, lower and more shut off from the light of day as the innermost sanctuary was approached. This could not but result in a tendency to making a terror of religion, and the hierarchy enhanced this impression on the lower orders by calling to its aid the use of scientific tricks and mechanical subtleties.

How different to the more modern ideal of concentrating the resources of art and shedding a brilliant light upon the central point of attraction in a place of worship, as most effectively seen in the chancel of a church. The soul of religion is not wrapped in mysterious veilings, and the faith of worshippers is invited to satisfy its cravings intelligently, not blindly. The accidental mysticism arising from what has been termed "dim, religious light" has been perhaps unduly insisted upon, as the feeling is probably the result of environment.

The fitness of pointed architecture for ecclesiastical buildings having been analysed in brief, what may be said about its suitability for State edifices? Firstly, it is evident that the more elevated the purpose of the building the more should it express dignity, formality, reserve, stateliness and continuity. It would be unpardonable to suggest that in most Governmental methods there is any continuity of policy in the generally accepted sense, and yet, on the principle that "under all circumstances the King's Government must be carried on," there is an underlying idea of continuity that should find expression in the "frozen music" of architecture. In Gothic art there is a lightness of touch, a certain irresponsibility and other qualities mentioned earlier, that militate against its fitness for the expression of State architecture; and whilst these qualities may recommend it for private and for certain public buildings, yet it is conceivable that other qualities may prove adverse to its free use even for these purposes.

The English Houses of Parliament are well adapted to point a moral, though they do not adorn the tale of nine-

Digitized by Google

teenth-century progress. Who does not recall Carlyle's denunciation of them ("Latter-Day Pamphlets"), written as the time of their completion approached? "A wilderness of stone pepper-boxes with tin flags atop . . . if this is ideal beauty, except for sugarwork and the more elaborate kinds of gingerbread, what is real ugliness? Can any earnest soul pass them without mentally exclaiming 'Apage!' and striking a pious cross in the air?" So far Carlyle. Dignity (that is, the expression of it) is at a discount, and where the whole surface is cut up into restless elaboration the expression of continuity is impossible; and with the absence of these is also to be noted the absence of formality (though not of stiffness by any means), reserve and stateliness.

When our eyes are turned to the English Law Courts in the Strand we see another phase of Gothic, also unsuitable. The Palace of St. Stephen's (criticised in the preceding paragraph) is Classic clothed in Gothic garb; the Law Courts renounce Classicism altogether and presents to passers-by a confused jumble of buildings that quite fail to typify the orderly process of law.

But when we regard the various blocks of Government offices within sight of St. Stephen's, their fitness is at once apparent, and we are in a position then to establish the justice of our adverse criticisms above and to absolve ourselves from any charge of jaundiced views.

In State architecture it is proper to include Royal palaces, where the predominating influence may indeed be traced to their public character, though the privacy attaching to a home must also find due expression. We may exemplify three Royal palaces here—one at Madrid (not the Escurial), one at Vienna, and one in England; all three are Renaissance in style. The Spanish palace exhibits a dignity, formality and symmetrical disposition that relegate it in appearance to the rank of a worthy Parliament House, for it bears no impress of domesticity. The Vienna palace, though less formal, shows just as few signs of the domestic character. Hampton Court Palace, however (we refer to Sir Christopher Wren's work there), by its greater freedom of treatment (and more particularly in the use of cheerful red brickwork as an integral portion of the design) acquires an air of combined stateliness and homeliness which in conjunction with its noble proportions and fair surroundings at once sets the palatial seal upon it and inspires in the beholder a sense of its absolute fitness. Gothic art in one or other of its phases may serve for private palaces, but with domestic architecture in general this article is not concerned.

There is one aspect yet to be considered before bringing this short analysis to a conclusion. When we talk of the qualities fitting for a certain building we are of necessity biassed in favour of, or at any rate predisposed to, a view that has grown with our and our country's growth, and this may be very different from the views held elsewhere and by other people. A popular example may render clearer what is here meant. Taking into consideration the "points" of beauty in a member of the so-called gentler sex, we are conscious of the fact that the sentiments of the Western nations in this respect differ widely from those of the Oriental races. In Turkey the ideals of womanly beauty consist in plenty of adipose deposit and henna-stained finger-tips; in China we are accustomed to connect long and sharply-pointed fingernails and the smallest of club feet with the Celestial ideals of womanly beauty. Even the Western nations have divergent notions; for whereas we regard with disfavour an English girl with a moustache, a Spaniard views his countrywomen as thereby adorned.

Consequently we must end, as we commenced, by avoiding dogmatism, merely submitting the foregoing considerations as a reasonable explanation of the general qualities of architecture in its relation to Church and State.

ANCIENT MEXICO.

AT the recent meeting of the British Association at Winnipeg, Miss A. C. Breton presented the following short papers:—

Race-types in the Ancient Sculptures and Paintings of Mexico and Central America.

The different race-types in the ancient sculptures and paintings found in Mexico and Central America form an important anthropological study. An enormous mass of material, evidently of many periods, includes sculpture, archaic stone statuettes, the portrait statues and reliefs at Chichen Itza, the Palenque reliefs and the series of magnificent stelæ and lintels at Piedras Negras, Yaxchilan, Naranjo, Copan, Quirigua, &c.

In terra-cotta or clay there are the hundreds of thousands of small portrait heads and figurines found at Teotihuacan, Otumba, the neighbourhood of Toluca and other ancient sites. Larger clay figures have been found in quantities in tombs, as in the States of Jalisco and Oaxaca; these were made as offerings, instead of the sacrifice at a chief's burial of his wives and servants. Small jadeite heads and figures, also found in tombs, show strongly marked types. If there are few specimens in gold, it is because throughout the country the Spaniards ransacked the tombs for gold. In painting there are the picture manuscripts, the frescoes at Chichen Itza, Chacmultun and Teotihuacan, and a number of vases with figures from Guatemala and British Honduras.

This material is now available for students in Mr. A. Maudslay's "Biologia Centrali-Americana, Archæology," Dr. E. Seler's collected works, the publications of the Peabody Museum, and the reproductions of the Codices by the Duc de Loubat; also in the splendid collections of the Museum für Volkerkunde at Berlin, the Mexican Hall of the Natural History Museum at New York, and the Peabody Museum.

Among distinctive types are:—The chiefs in the reliefs at Xochicales, who sit cross-legged; the little shaven clay heads at Teotihuacan; the tall, well-built priests, with protruding lower lip, of the Palenque reliefs; the fifteen caryatid statues in feather mantles of the Upper Temple of the Tigers, at Chichen Itza; and the sixteen stern warriors carved at its doors, these last similar in type to some of the modern Indians of the villages near Tlaxcala.

There are portraits of the Mexican kings on the border of a picture-map which represents the western quarter of Tenochtitlan and of the householders in that part of the city. Of female types there are the painted clay figures of Jalises with compressed heads. Some of them have short, broad figures; others are slender. Both types still survive. The queenly woman in Codex Nuttall-Zouche, and the women-chiefs of the Guatemalan stelæ belonged to a different caste to the obviously inferior women on those stelæ, fattened in preparation for sacrifice.

Herr T. Maler's most recent explorations on the borders of Guatemala have given magnificent results in the finding of thirty-seven stelæ at Piedras Negras, and at Yaxchilan twenty stelæ and forty-six sculptured lintels. The superb figures of warriors and priests indicate a race of men of tall, slender stature and oval face, with large aquiline nose, whilst the captives appear to be of a different race.

Arms and Accoutrements of the Ancient Warriors at Chichen Itza.

Chichen Itza, in Yucatan, is as yet the principal place in the region of Mexico and Central America where representatives of armed warriors are found. There was a remarkable development in the later history of the buildings there of painted sculptures and wall-paintings, mostly of battle scenes and gatherings of armed chiefs.

The stone walls of the ruined lower hall of the Temple of the Tigers are covered with sculptured rows of chiefs, who carry a variety of weapons. Of the sixty-four personages left, half a dozen have ground or polished stone implements; others hold formidable harpoons (two of them double) or lances adorned with feathers; whilst the majority have from three to five spears and an atlatl (i.e., throwing stick). These are of different shapes. One figure has armlets with projecting rounded stones. Some have kilts, sporrans, leggings, and sandals. Eleven personages have tail appendages. There are protective sleeves in a series of puffs, breastplates, helmets, and feather headdresses, necklaces of stone beads, masks, ear and nose ornaments in variety. Small round back-shields, always painted green and fastened on by a broad red belt, may have been of bronze attached to leather, as a bronze disc has been found. Round or oblong shields were carried by two thongs, one held in the left hand, the other slipped over the arm.

The two upper chambers of the same building have reliefs on the door jambs of sixteen warriors life size. They carry a sort of boomerang in addition to spears and atlatls. In the outer chamber was a great stone table or altar, supported by fifteen caryatid figures. Upon its surface was a relief of a standing chief, holding out his atlatl over a kneeling enemy who offers a weapon. The walls of both chambers were covered with painted battle scenes, in which several hundred figures are still visible. They carry spears, atlatls, round or oblong shields, and a kind of boomerang which was used by the natives in Australia about eighty years ago. It was

Digitized by Google

HEADINGTON CHURCH, OXON.—FROM A SKETCH BY P. HUBERT KEYS.

intended for striking rather than throwing. On one wall the method of attacking high places by means of long-notched tree-trunks as ladders and scaffold towers is shown.

The building at the north end of the great Ball Court is evidently very ancient, and its sculptured walls have chiefs with spears and atlatls. The temple on the great pyramid called the Castillo also has warriors on its doorposts and pillars, with boomerangs, spears and atlatls, and so has a building in the great Square of Columns. In an upper chamber of the palace of the Monjes are paintings in which are men with spears and atlatls, and also spears with lighted grass attached thrown against high-roofed buildings. A survey of all that has so far been discovered at Chichen gives a vivid idea of primitive battle array.

LETCHWORTH—A CRITICISM.

IN view of the Housing and Town-Planning Bill, much interest attaches to Letchworth, where the first complete experiment has been made in scientific town-planning. Therefore it is interesting to quote the first report on the garden city just made by Dr. Freemantle, who is the medical officer of health for Hertfordshire, and says he recognises the importance of the experiment from the sanitary, social and economic points of view. Letchworth, which includes two other villages, comprises about six square miles, and was bought in 1903 for 151,570*l*. Then the population was only 416; now it is 5,500. In March last year Letchworth was created a single parish, with a parish council, and since then its development has been rapid. The object of the directors is to give practical proof of economic, social and sanitary value in the designing, from the outset, of an ideal city of modern conditions on practical lines, surrounded by a permanent belt of agricultural land, the whole to accommodate a mixed industrial and rural population, limited to 35,000. While the urban area of 1,318 acres, including 200 acres of parks and open spaces, is developed for all the purposes of a mixed industrial community, the agricultural belt of 2,500 acres is being in part prepared for small holdings, and in part continued in larger farms.

The position at the end of June this year was as follows:—Population, 5,500; houses built and in course of erection, 1,051; factories and workshops, 33; shops and (3) banks, 55; hotels (2 licensed, 3 unlicensed), 5; places of worship and public buildings, 9. The rates are 4*s*. 8*d*. in the £. The capital value of the buildings erected is estimated at 353,700*l*. The value of the Company's estate, apart from timber, gravel, and the gas, water and electric works as commercial undertakings, is 379,500*l*., which shows a net increment in value over expenditure of 97,000*l*. There are good shops and stores catering for the working-class trade, ample and convenient cottage accommodation, and an ample supply of labour. Last October a public market was opened, and a public elementary school is being built by the County Council at a cost of 8,975*l*.

Dr. Freemantle observes that an experimental community of this nature gives scope for original ideas of many kinds, but it is to be judged by its principles and by its result, not by subsidiary enterprises that are an incident in its growth. Opinions only differ as to the value of the several minor experiments which are put to the test in the city.

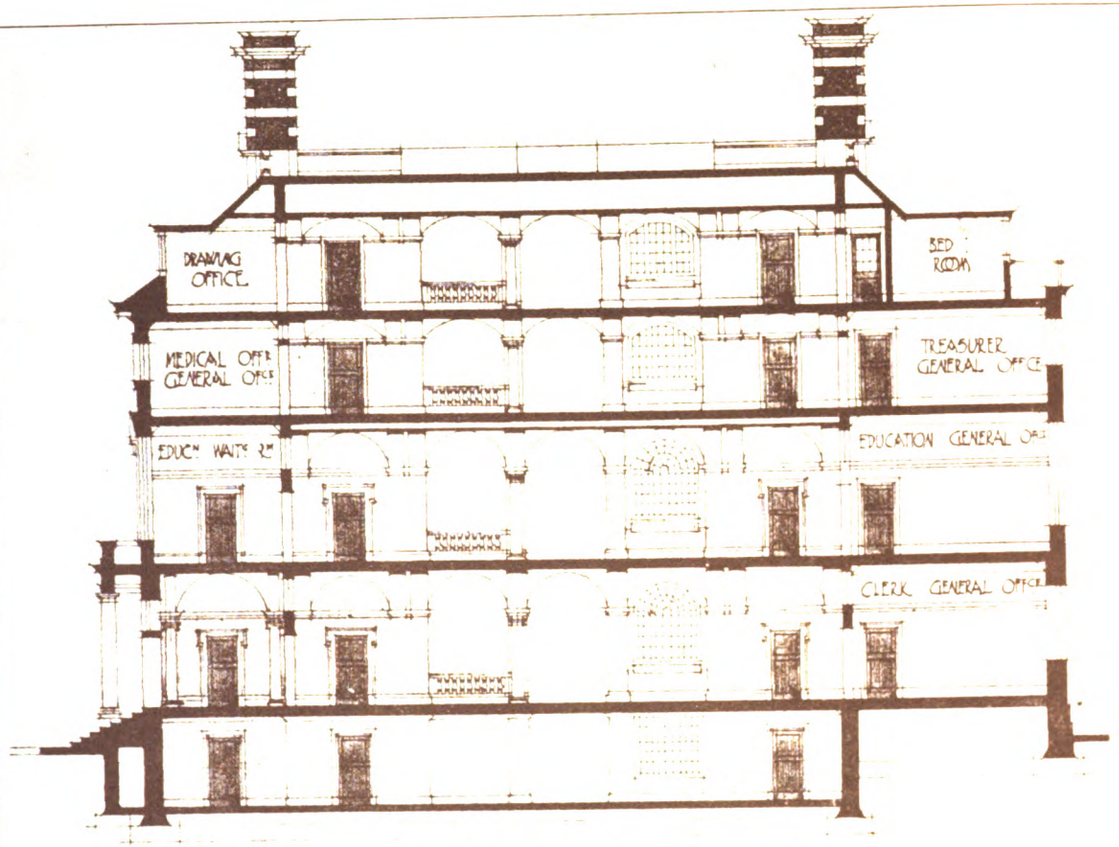
The need for rapid building gave an opportunity for experiments, independent of the main scheme, in the direction of cheap housing, and an exhibition of rural cottages in 1905 served to stimulate the provision of a large number of houses of various designs. The aim was achieved of erecting a well-designed and adequate cottage, with three bedrooms, for 150*l*., this figure not including the cost of the land, builder's profit, or architect's fee, whilst the cost of bricks and cement is low in the locality. Another exhibition in 1907 led to the erection of fifty urban cottages and homesteads suitable for small holdings, the smallest price for the former being 175*l*. and for the latter 250*l*.

Concerning these houses, the medical officer remarks that most seemed too often designed rather for elegance than for the use of artisans, and proceeds to say that the cost was often reduced only by the use of unseasoned material or thinness of walls. Nine-inch walls are "unpleasantly thin in this country."

The death rate last year was only 6.3 per 1,000, the lowest in Hertfordshire.

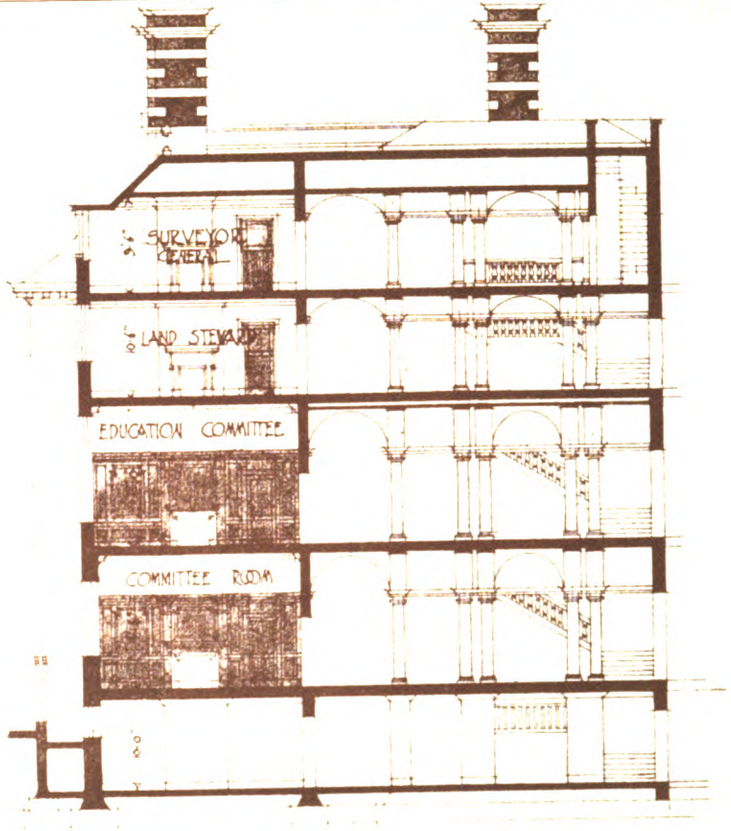
ILLUSTRATIONS.

NEW WEST WING, TEMPLE DINSLEY, HERTS.



THE drawing from which our illustration is taken was exhibited this year at the Royal Academy and is an example of Mr. EDWIN L. LUTYENS's study of a particular phase of English eighteenth century domestic work, quite in keeping with the feeling of Hertfordshire.

SELECTED DESIGN FOR BERKSHIRE COUNTY COUNCIL OFFICES, READING.



WE illustrate the winning design by Messrs. WARWICK & HALL, of which a full description appeared in our review of the drawings last week. The materials, as stipulated in the conditions of the competition, are red brick and Portland stone, with tile roofs. We shall give in a future number the designs placed second and third.

THE USE OF FERRO-CONCRETE IN MONUMENTAL ARCHITECTURE.*

FERRO-CONCRETE has helped to achieve great works of engineering, and so has become a factor in modern technical work. Ferro-concrete being now frequently used as a substitute for constructions previously in general use, such as flat or vault-like ceilings, beams and pillars, the question arises for the architect to what extent this peculiar material and the forms of construction dependent on it can be utilised in a suitable manner in monumental architecture. This question not only deals with technical substitutions for forms of construction already known which may be more or less justified, but it enquires also whether the peculiarity of this material does not offer important motifs which would lead to a form of construction peculiar to this kind of architecture and which would not imitate any of the older methods of construction.

None of the older forms of building furnish a model for the use of this peculiar material; on the contrary, it differs substantially from any other material or form of construction in use. Whilst up to now all materials were brought to the building site as complete entities (such as tiles, bricks, wood, iron, &c.), and were only rendered more sightly by an overlay of other material after they had been put in position, concrete and ferro-concrete construction can be produced on the site, or parts which have been finished beforehand can be put together on the building.

The manner of construction therefore may be classified in three divisions—namely, (1) Construction on suitable scaffolds in the building; (2) building material in ferro-concrete made beforehand in the factory (artificial square stones, pillars and beams); or (3) construction in a combination of Nos. 1 and 2.

As it is possible to construct by these methods vaults or vault-like forms, flat or shaped ceilings of all kinds, pillars and beams, the whole field of monumental architecture, which embraces the construction of ceilings, pillars and beams, is open to ferro-concrete as soon as it is possible to connect therewith such forms as are specifically appropriate to it, and in such a manner that the appearance of these parts of a building excludes to an expert all idea of being an imitation of construction in any other building material.

In examining the question we have therefore to look at it from three points:—

1. Construction made on centering on the building site.
2. Construction made of concrete bodies which were finished before they came to the building site.
3. Combined construction of 1 and 2.

We further have to divide the question as concerning the use and form of ferro-concrete construction into the elements of architecture, such as ceiling construction, beams and pillars, in

(*a*) Ferro-concrete construction as ceiling construction, which means ceilings more or less flat and vaults.

(*b*) Beams and pillars. Here we must take again into consideration the divisions 1 to 3 as mentioned above. Construction of beams and pillars has to be looked upon as monolithic work, not as a collection of separate parts, because when pillars and beams are constructed of ferro-concrete they are not formed piecemeal, but appear as a uniform piece of construction.

Construction of Ceilings upon Centering.

The usual manner of constructing ceilings whether more or less flat or of vaulted form consists in laying them on a centering that gives exactly the form desired. When the concrete has hardened sufficiently the scaffold is removed and the ceiling plastered and afterwards decorated with artistic ornaments in the same way as by other forms of construction. The difficulty of giving the centering other forms than the most simple is an obstacle to practically inducing the ferro-concrete to take any desired shape, even if there is an appropriate basis for it—that is to say, a mould.

However, it would be quite possible to contrive other moulds in wood and so secure an appropriate treatment of the lower surface, as can be seen by figures 1, 2 and 3. By the application of flat, dish-like moulds (of metal or wood) on the centering, a further characteristic treatment can be obtained (fig. 4). With dome-shaped ceilings naturally the diameters of the moulds must be gradually diminished. In order to avoid the cost of making new moulds for every building the use of stereotyped forms is to be recommended, which makes it possible by means of iron frames or fittings to adapt them to the size required.

Another way of developing this kind of construction is to leave openings in the middle of the moulds in order that later ornamental pieces (rosettes or the like), also made of concrete, may be attached (figs. 5 and 6); this leads further to the method of bedding in the concrete of the ceilings ornamental pieces constructed separately. By means of dovetails these pieces must be connected firmly to the ceiling under construction. The centering must be either hollowed out or be provided with firrings according to whether the ornamental pieces are to be projecting or recessed from the general surface (fig. 7). In constructing ceilings upon centering, especially if vaulted, the manner of arranging the springing of the ceiling or vault from the supporting wall must be considered. As the ceiling or vault will only act as a superincumbent load, this can be expressed by arranging that horizontal corbelling marks the separation from the wall surface, which can be emphasised by further small fascias (by means of moulds) (fig. 8).

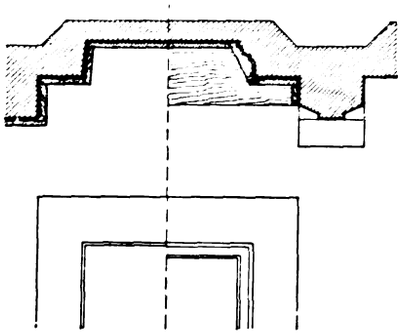

FIG. 1.

From this method of treatment we come to the consideration of other forms, which show in a suitable way connections to pillars by a further use of corbels or consoles (figs. 9 and 10).

Construction of Ceilings from Concrete Parts Made Beforehand.

The ability of concrete to adopt in a suitable mould the finest ornamental form (fig. 12), so that even ventilator and warm air openings may be ornamented, is taken advantage of by the construction of ceilings from concrete parts made beforehand. The parts so made are placed in the usual way between supports, and as the concrete has absolutely smooth surfaces there is no finishing necessary, and the work on the ceiling can at once be gone on with by painting, &c.

The first essential therefore in arranging this kind of construction is the use of such moulds as allow the casting of concrete, and thus we avoid the imitation of a wood or plaster ceiling by this construction.

The kindness of the Ministry of Justice made it possible for me to execute such ceilings at the Law Courts of Salzburg and Brünn.

The first of these was a coffered ceiling (fig. 11) with square coffers of 120 cm. in length of side for the chapel of the prison at Salzburg, weight 160 kg./m², in the form of a barrel vault of 3 to 7 cm. thickness, with iron reinforcements of 9 mm., in groups of five.

A test made under official supervision showed that the stress of 1,180 kilograms per square metre had no effect; another test, made by letting fall a piece of granite weighing 14½ kg. from a height of 5 m., caused no more than superficial damage at the place where the stone had struck. Gypsum was used in making the moulds. The result of these tests permitted the reduction of the thickness. The setting was done with white lime mortar. In this manner an absolutely firm ceiling covered with a straight roof in tiles and plaster has been constructed. If the covering is not required, the thickness of the ceiling can be still further reduced and a smaller amount of iron ties can be used.

A test made with a coffer which was painted in polychromatic cement colours, and which had been exposed to the open air for more than one year, showed no loss in the painting, which had been made direct upon the concrete without any other ground being put underneath.

A similar coffered ceiling was made for the jury-room at Salzburg, weighing 154 kg./m². (fig. 13). In this case the ceiling was constructed with a cove connecting it to the wall surface.

For the main staircase in the Law Courts at Brünn (fig. 14) a concrete ceiling with deep cove was executed; the

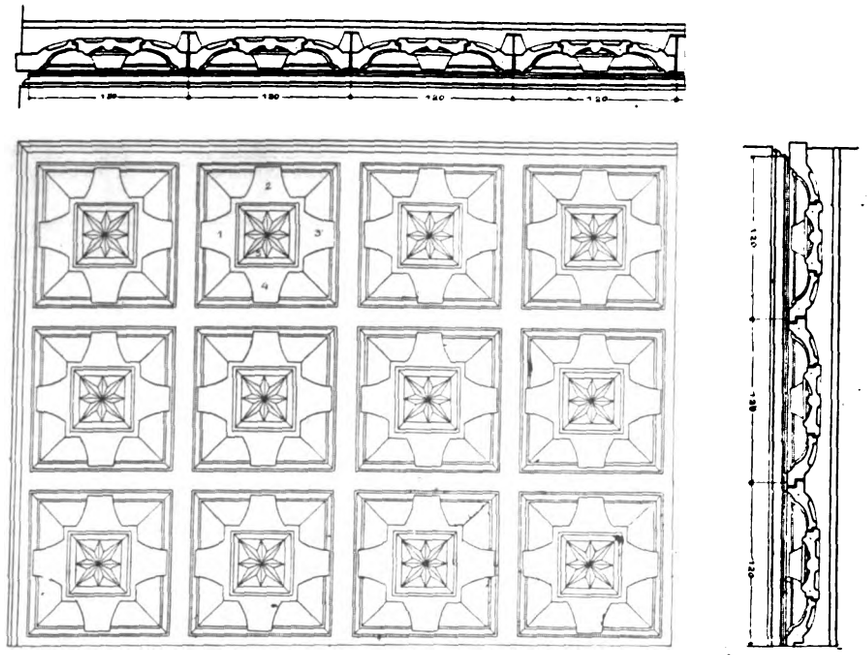

FIG. 11.

parts which formed the cove were made in small pieces on account of the weight.

In setting out the coffers it is necessary to take care that the weight of a single piece is not more than 60 to 80 kg., so that two workmen may be able to carry it without being compelled to use a lifting apparatus. There is no need for any supplementary concreting, which at first was thought to be necessary.

In the Law Courts building at Brünn a ceiling of rectangular coffers (fig. 15) was constructed, and the principle of ceiling between beams has thus been extended to rectangles of 30 to 50 cm. width and 120 to 130 cm. length.

A vaulted form of coffered ceiling or a flat coved ceiling as well as the coffering of a flat ceiling are most characteristic for a construction made of soft material in a hollow mould,

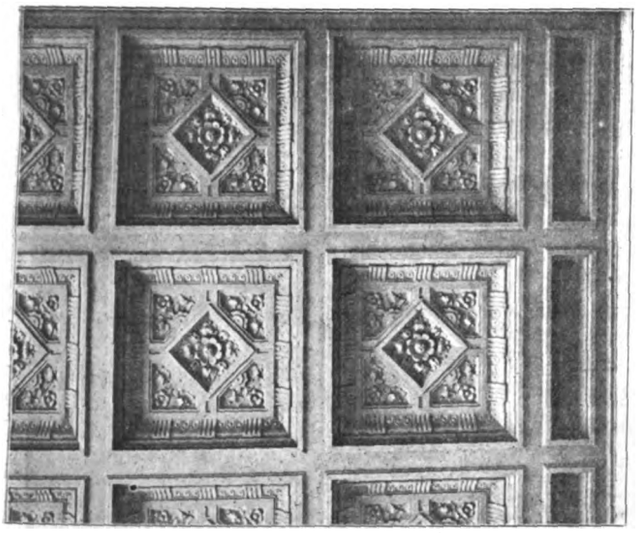

FIG. 12.

so that there is no imitation of ceilings constructed of wrought wood or plaster.

In all these ceilings formed with coffers their connection is effected by means of beam-members, which are so arranged that the joints are covered by projecting parts. The cost of this construction is not greater than that of an ordinary concrete ceiling with ornamental covering of wood or stucco attached to it.

Thus the question of constructing a concrete ceiling which requires nothing else except painting has been solved.

The beams, if such are used as in the case mentioned, may remain visible or can be plastered.

The bearing capacity of concrete allows one to use concrete coffers made beforehand for the construction of vaulted ceilings without using close centering to them.

If such rectangular or square coffers which have been made of one piece, except perhaps a centrepiece or rosette, are joined together by pieces in the shape of dovetails or joggles in the direction of the pressure of the vault, then it is clear that there is no need for other support than the centering required for forming the desired arches. A ceiling (fig. 16) of this kind in segment form has been constructed for an entrance hall of the Law Courts weighing 150 kg. per m². With a span of 4 m. the compression amounted only to 3 mm.

This kind of construction would also be possible for large vaults and domes; the coffers are to be applied in annular zones from the counterfort upwards, and are bound together by the concrete filling, which must also be in annular zones. By the coffers which are connected one with another a support of sufficient bearing capacity is produced, so that the concrete filling can be put upon it straight away (fig. 20).

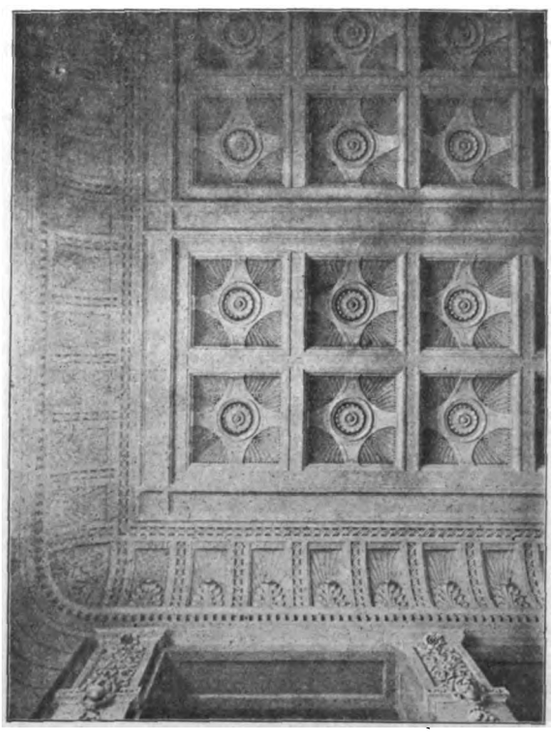

FIG. 13.

With circular or polygonal constructions trapezoid-formed coffers or sections are necessary. The centre rosette is better put in afterwards in order to reduce the weight, which is of importance in handling the pieces when fixing them. The jointing of the coffers one with another and of the centre-piece is effected by dovetails, by pins, or by ferro-concrete dowels.

A design for a church holding about 4,000 persons in a large town, and where the width of the nave is 20 m., which was made a few years ago adopts the form of a pointed barrel vault which has been ceiled independently of the iron roof construction (fig. 17).

The homogeneity of concrete, and the experience gained by the construction of the above-mentioned entrance hall at

FIG. 14.

Salzburg, allows one to think that it is possible by joining several coved members to execute in concrete such ceilings as those of the Italian churches (Rimini, Verona, &c.), which have been made in wood (fig. 19).

Shapes of Beams and Pillars.

The shapes of the beams constructed of ferro-concrete depend mostly upon the necessity of making them on the

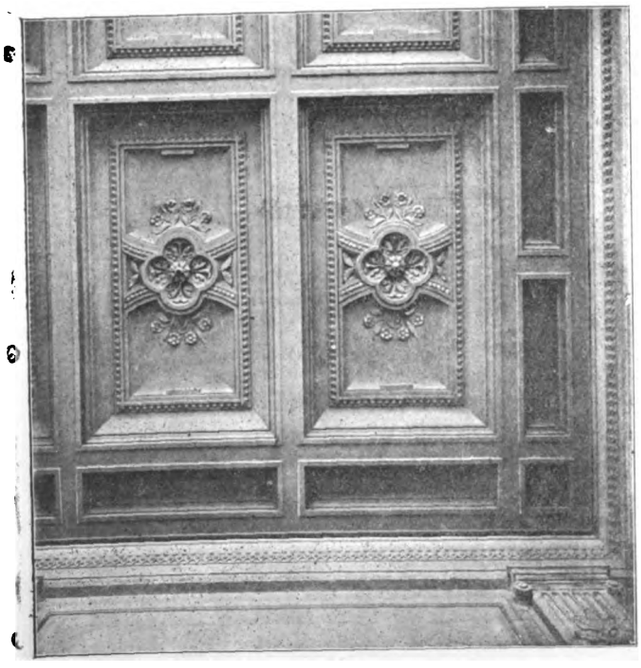

FIG. 15.

building site, because only those of small size should be transported ready made to the site of the building on account of the difficulty of transport and the probability of damage.

The shape of the beams is dependent on the form of the mould; a decorated surface and sides are easily made (fig. 20).

With beams made on the spot the simple forms which

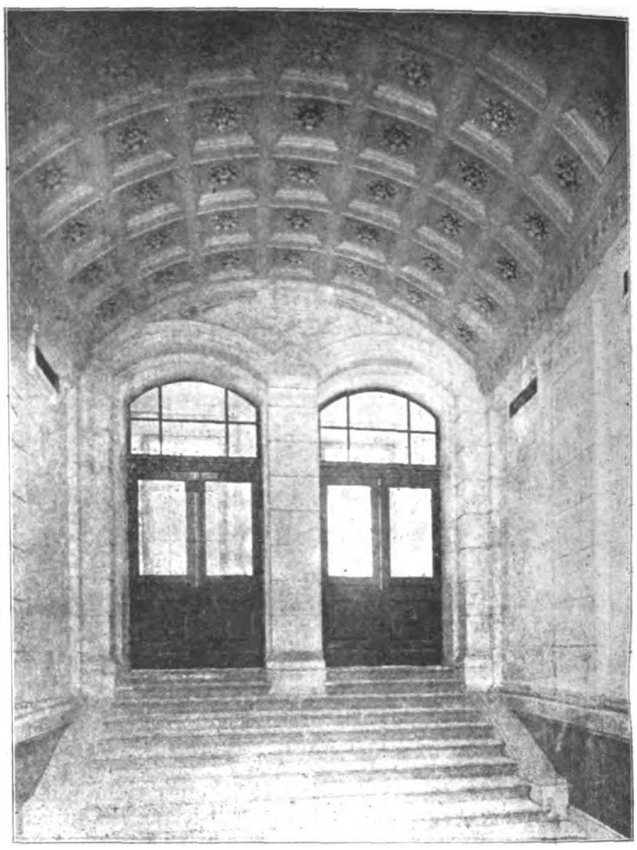

FIG. 16.

are obtained by concreting around ready-made ornamental pieces inlaid on the wooden centering should be taken into consideration.

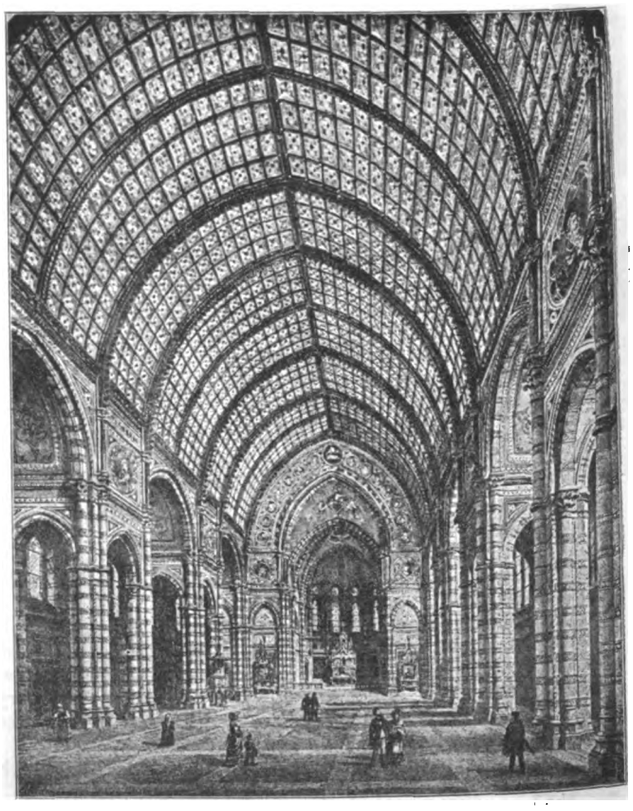

FIG. 17.

In order to reduce the weight hollow beams with or without projecting ribs can be used. As insets in the casting

Digitized by Google

moulds only simple forms, sloping or flat grooves, should be considered. Insets of metal may very well be used in order to lessen the need for finishing the concrete by means of lime plastering as much as possible.

For beams requiring decorative architectural treatment on the side, such as lintels over windows and doors, one has to use moulds which are placed to give a lateral view (gypsum, wood, or concrete) on the centering; the tests made with this arrangement have given satisfactory results, for it has been seen that concrete gives the exact forms when the mould has been placed in a lateral position.

Besides the straight form of beams the arch form has also to be considered, and this can be attained by a polygonal approximation to the line of an arch in the centering.

This form is of special importance when we have to deal with the design of the nave of a church or with the building of a hall, as then the lower beams so formed can be utilised as supports of a flat roof, and thus any further roof construction, except purlins from beam to beam, becomes superfluous.

Closely connected with the form of the beams is that of the projections, which can easily be obtained in concrete construction in the shape of corbel or console-like forms.

THE USE AND ABUSE OF DRIERS.*

A NUMBER of oils are known which, when exposed in a thin film to the action of air, take up oxygen, and are transformed into a hard, elastic, non-sticky product.

The power of absorbing oxygen is possessed by many fatty oils: when exposed to the air slow oxidisation takes place accompanied by complex chemical changes. In many cases this property has no commercial value, while in other cases it has been utilised to cope with practical needs. Among the drying oils which may be mentioned are hemp seed oil, poppy oil, sunflower oil, walnut oil, &c., but the two drying oils *par excellence* are linseed oil and Chinese wood oil, the former of which is of paramount importance to the paint and varnish industry.

Linseed oil is obtained from Russia, India, South America, and large quantities are now produced in the United States of America.

The quality of the oil varies considerably according to the attention which has been bestowed on the flax plant. The manure used, weather conditions, and the time of harvesting all play an important part on the resulting oil obtained from the seed. Since greater attention has been paid to these details the quality of the oils obtained from India and South America have been considerably improved, although the oil exported from the Russian ports is still considered the best.

Linseed oil undergoes oxidisation when exposed to the action of the air, and this change takes place more rapidly when the oil contains a high percentage of linolenic acid and isolinolenic acid glycerides.

Olive oil absorbs oxygen extremely slowly (5.2 per cent. is taken up in twenty days. Linseed oil absorbs 12 to 20 per cent. in one to seven days according to the conditions), and bodies of the type represented by stearin undergo no change under normal conditions.

The glycerides of myristic, palmitic, and lauric acids, which are always present in linseed oil, are saturated compounds, similar to the glyceride of stearic acid already described, and these, together with the olein (glyceride of oleic acid) take probably no part in the reaction when a film of linseed oil dries. Their presence gives elasticity to the oil film, but under the influence of light, heat, and moisture, *i.e.*, changing atmospheric conditions, even these substances undergo profound change, the oil film becomes hard, then cracks, and finally disappears.

Andés made some experiments with mixtures of linseed oil containing driers and maize oil. With mixtures up to 50 per cent. of maize oil he obtained dry films in twelve hours. No results as to the effects of weathering on these films were published.

The changes which take place when linseed oil undergoes oxidation were first studied by Mulder. He stated that glycerine is first set free, and this is oxidised to formic, acetic, and other acids, while the linolic, linolenic acids, &c., set free are converted into anhydrides by the oxygen, and finally pass over into linoxyn by further oxidisation. This is a white substance insoluble in ether, the basis of all oil films. The fatty acids when liberated from linseed oil do not dry so rapidly as linseed oil itself, so the actual change which takes place is not that denoted by Mulder.

Hazura proved that the insoluble material obtained from oil films contained glycerine, so it is probable that the glycerides take up oxygen, and this action is accompanied by a polymerisation, *i.e.*, certain properties of the bodies under consideration cause the unsaturated molecules under the influence of the oxygen of the air to join up into groups of a more stable and complex character. It would lead us too far to inquire too closely into the composition of these oxidation products; the results that have at present been obtained are not of a very definite character.

Linseed oil, even under the most suitable atmospheric conditions, takes several days to dry, and for practical purposes it is necessary to accelerate the oxidation. The salts of certain metals, *e.g.*, manganese and lead salts, commonly known as driers, have been found to exert this action.

The addition of these substances does not improve the quality of the oil; on the contrary, pure oil, which has not been altered by artificial, chemical, or physical treatment, undoubtedly gives the most durable coating when it has been allowed to oxidise under suitable conditions. As driers play such an important rôle in the paint and varnish industry, it will be advisable to first consider the theories that have been suggested to explain their action, before the bodies themselves receive separate treatment. Years ago Mulder explained the drying action of manganese borate by considering it as a carrier which absorbed oxygen from the air and gave it up to the linseed oil. On the other hand, he considered that red lead partly acted in this manner, but at the same time it parted with a portion of its combined oxygen and directly oxidised the oil. By describing driers as catalytic agents, *i.e.*, substances which increase the velocity of a chemical process without themselves undergoing apparent change, Weger was a step in advance of Mulder, because, while the latter considered the salt manganese borate as the active agent, the former realised that the quantity of metal present was the factor to be considered. During the last few years the theory of autoxidation has been put forward: this hypothesis explains processes of oxidation which were formerly little understood.

The oxidation of linseed oil is such a complex process that an explanation which is intelligible to the non-scientific and at the same time fruitful in conclusions deducible from it for the exact comprehension of driers and their sphere of action is somewhat difficult to formulate.

Exact experiments conducted under certain fixed conditions have shown that during the drying process oxygen is first slowly absorbed, and after a certain interval of time the oxidation takes place much more rapidly.

Now this is contrary to general experience. The velocity of most chemical reactions is greatest at the commencement, and then gradually becomes less as the reaction proceeds. How can this be explained? Why should the oil at a certain stage in the drying process with or without the presence of driers absorb oxygen much more rapidly than at the beginning of the oxidation? One is almost forced to the conclusion that some substance must be formed during the oxidation process which further accelerates the oxidation. Reasoning by analogy with other chemical reactions it was assumed that, when oil is exposed in a thin film, one of its constituents is acted upon by the oxygen of the air, and a compound known as a peroxide is produced. This material directly oxidises another portion of the oil, and the energy evolved by this reaction still further accelerates the production of more peroxide.

It appears that the presence of driers does not increase the initial velocity of absorption, but that the period of slow absorption is much slower than is the case with raw oil. Thus it is evident that the oxygen absorption of a boiled oil does not differ in character from that of the raw product, but the presence of the drier accelerates the formation of the peroxide which is the ultimate factor in the conversion of the oil into the insoluble elastic product which is the basis of the oil film.

It has been previously stated that the presence of a drier in linseed oil does not improve its lasting qualities when in the form of a film. If the peroxide mentioned, or some efficient substitute, could be introduced into raw linseed oil, which would give it drying properties, then a great industrial advance would have been made. Weger some years since made experiments somewhat on these lines, but instead of employing peroxides, he made use of organic bodies which are readily affected by oxygen. Negative results were obtained, and for a time no other experiments were attempted in this direction. Other investigators have since employed true peroxides and it has been found that the presence of these bodies does accelerate the drying of linseed oil. Although I do not know any peroxide on the market which will efficiently replace the driers at present used, improvements in this direction are taking place, and when I deal with the effect of light upon the drying oils I shall again have occasion to mention this subject. Some years since a very powerful dryer was suggested by C. Toul. He separated the fatty acids from linseed oil, oxidised them with potassium permanganate, and precipitated a manganese salt from the material so obtained. According to the statement made by this author 25 per cent. of this salt will cause linseed oil to dry in 7½ hours. The author only claims that it is a manganese salt of various oxyacids, but if the drying powers are as stated, I think it most probable that a manganese salt of some peroxidised body must be present.

When it was first proved that linseed oil could be made to dry more rapidly by treating it with litharge, many other bodies were as a natural consequence tested as to their action in this respect. Experience proved that of all the substances brought into requisition only those containing either manganese or lead were effective.

There is mention in the literature of the subject of metals other than those mentioned having been found to accelerate the drying of linseed oil. Finely divided copper exerts a marked action, whereas porous inert materials which offer an equal surface to the oil are non-effective. White cop-

Digitized by Google

peras and the oxides of calcium and barium, &c., in some cases improve the drying, but their activity is very much less pronounced than that of the aforementioned metals manganese and lead, and it is probable that the improved drying observable is due to a physical hardening effect rather than to an acceleration of the oxidation.

The various compounds of manganese and lead offered a wide scope for investigation. Acetates, borates, carbonates, citrates, nitrates, sulphates, oxides, hydroxides, oxalates, &c., of these metals were introduced to manufacturers, and with the pronounced liberal spirit so evident in the paint and varnish industry each manufacturer selected a more or less complex combination of these materials, called it his drier, hugged it as a great secret, and was perfectly contented with his superior position in relationship to his contemporaries. It is now known that the metals are the effective agents and that the inorganic or organic acids with which they are combined are only of importance in relationship to the ease or difficulty with which the metals can be taken up by the oil. Expensive salts of manganese and lead offer no advantages, and the practical driers resolve themselves into the following:—

Commercial Driers (Lippert).

Drier.	Theoretical Percentage of Metal.	Average Percentage of Metal.	Minimum Temperature at which drying oils are produced.
1. Manganese hydroxide	62·5	45–50	170°–200°, but 200°–220° is more certain.
2. Manganese peroxide	52·4	45–50	
3. Litharge	92·8	about 93	Are all taken up by cold oil under suitable conditions.
4. Manganese borate	—	5–15(–22	
5. Manganese acetate	22·5	about 22	
6. Lead acetate	54·6	about 54	
7. Manganese resinate (ppt)	7·7	about 7 sol.	Soluble in cold oil.
8. Manganese resinate (fused)	5·3	2·5–4·5 fused	
9. Manganese linoleate	8·9	about 9 sol.	
10. Lead manganese resinate (melted)	—	—	
11. Lead manganese linoleate	—	—	
12. Manganese sulphate	—	—	

One and two are comparatively insoluble compounds which require heat for their solution, while 3 to 7 are taken up by cold oil when effectively mixed with it. This method would not be suggested for the preparation of drying oil. Manganese and lead acetates melt when heated in their water of crystallisation and are more satisfactory if used in the anhydrous condition.

The remaining compounds, 8 to 12, are the so-called soluble driers; since their introduction in 1885 they have found wide application in the paint and varnish industry.

Experience has proved that a drier, e.g., hydrated manganic oxide, is not always equally soluble in linseed oil although the analytical results may be quite satisfactory. The physical condition of the particles materially affects the value of the product. For this reason practical tests are even more necessary than chemical tests when an opinion is to be given on a drier. It has been shown that manganese borate is completely soluble in twice its own weight of glycerine, and this mixture has been patented as an effective drying agent.

The soluble driers vary more in character than the inorganic products. We know that linseed oils vary greatly in constitution among themselves, consequently the salts prepared from them, particularly when obtained by a process of fusion, are even more variable in character and cannot be judged according to a fixed constitution. This argument applies even more strongly to the resinates, which also vary considerably according to the resin which has been employed in their production.

Both the resinates and linoleates should be free from uncombined inorganic oxides which are insoluble in oil at the comparatively low temperature at which the soluble driers are employed.

Although resinates have found extensive application in the paint industry, I do not consider them suitable driers for paint which is intended for outside use.

As driers, lead and manganese each have their own sphere of action. It should be a postulate of the paint and varnish industry that the smaller the proportion of driers contained in a dried paint or varnish film the more durable the coating. Even if molecular proportions are considered manganese is a more effective drier than lead. When durability alone is the consideration manganese should be the drier used, but in many cases other conditions have to be satisfied. Although the dried coatings obtained from manganese oils are practically colourless, the oils themselves are, generally speaking, more highly coloured than when lead is the drier used. For this reason white paints prepared with manganese oils give one the impression of being off colour, although this disadvantage does not appear after application.

(To be concluded.)

NOTES ON BOOKS.

"A Practical Treatise on Bridge Construction." By T. Claxton Fidler, M.Inst.C.E. Fourth Edition. (London: Charles Griffin & Co., Ltd.)

THE fourth edition of this standard work has been improved in several directions. The difficult problem of the determination of a safe working stress, less rough and ready and more accurate than the old-fashioned method of simply dividing the ultimate breaking weight of the material by an empirical factor of safety, is discussed more fully in the light of further observations and experiments made since the previous editions were published. In bridges more than in many other kinds of building the subject is of considerable importance, as it is an essential condition of a bridge that it is subjected to variable loading. Hence Professor Fidler, in dealing with bridge construction, cannot neglect the question of working stress. At the same time he points out rightly that a safe working stress is not alone sufficient to ensure the stability of a structure. A further difficult and interesting question is that of the effects of wind pressure, and here the experiments of Professor T. E. Stanton have been utilised as the basis for further deductions; but this subject still remains open for many more investigations. It seems to us that the experiments made up to the present have been too much restricted to very small surfaces and to direct currents. We are inclined to believe that in wind action there is a great deal of variation in effect due to what we may call cumulative intensity, and that the degree of this intensity is largely dependent upon the area of obstruction to the wind current and to the angle between the current and the plane of obstruction. In yacht racing it is well known that a very slight alteration of the plane of the sails has a considerable effect on the dynamic action of the wind. Moving air is a fluid, and when obstructed endeavours to flow past the obstruction, its effect upon which must vary with the precise direction and rapidity of flow. The chapter on the theoretical strength of columns is now more valuable even than before, the table giving the calculated breaking weight of columns being given in a more extended form. The high position that Professor Fidler's work has obtained as a standard will be more than ever firmly maintained by the new edition.

"A Restoration of the Mausoleum at Halicarnassus." By J. J. Stevenson, F.S.A. (London: B. T. Batsford. 2*s*. 6*d*. net.)

Few of the monuments of antiquity have excited more speculation as to their original form than the Mausoleum at Halicarnassus, partly from the fame of this monument throughout the ancient world, partly from the incompleteness of the data on which any restoration must be founded. Sir Christopher Wren, Hawkesmoor, Cockerell, Watkiss Lloyd, and Edward Falkner were all working very much in the dark, their conjectures being based on the descriptions only of Pliny, Hyginus, and Martial, with the story of its destruction by De la Tourette and the Knights of Rhodes. It was only after Sir Charles Newton had discovered and brought to England what remains of the Mausoleum and may now be seen in the British Museum that any satisfactory basis existed for reconstructing the design of the monument. Even now there is room for conjecture, and hence the interest of the late Mr. Stevenson's attempt, which we will not follow here but which certainly is very well argued and has, to our mind, the appearance of probability rather than plausibility.

"Art in Great Britain and Ireland." By Sir Walter Armstrong. (London: William Heinemann.)

Two or three years ago Messrs. Heinemann published a guide hand-book to the art of the world under the slightly misleading title of "Apollo." The author, Dr. Soloman Reinach, had a choice of many methods of treating the subject before him, and he chose the pictorial one whereby his letterpress was more or less subservient to the illustrations, two or three of which were introduced into every page of text. It was therefore an essentially "popular" manual, and one calculated to appeal to the public, who would never be attracted by an abstract treatise on æsthetics. The attempt to compress the art attainments of the Old World into some three hundred odd pages, of which space a third was occupied by illustrations, might seem absurd. But it assumes a different character when offered as a preface or introductory chapter to a series of similar manuals each of which would deal with the art of a particular country. Such was its evident purpose, for the publishers have just issued a precisely similarly arranged handbook on "The Art of

Digitized by Google

Great Britain and Ireland," which states that they purpose to bring out a series of fifteen more, each dealing with the art of one country and people, and written by an acknowledged authority of that particular country. The catholicity of the scheme is ensured by its simultaneous publication in French, German, Italian, and Spanish, as also in the United States. It must have required some boldness to have inaugurated this excellent scheme by the volume dealing with the United Kingdom. This country does not by any means enjoy the reputation of having served as the cradle, and still less as the home, of the arts during present or past centuries. But any impression that we are a nation of barbarians should be severely shaken by this latest book, which gives a bird's-eye view of our artistic achievements. There have been, of course, dark periods when the iconoclast, the vandal, and the scoffers reigned supreme and unchallenged—that is to say, as Sir W. Armstrong expresses it, there have been untimely catastrophes, each of which came at a critical period, "and took a course which ensured the largest possible amount of destruction and dislocation." But these miscreants were only productive of painful interludes, and failed to eradicate the tree of art, whose roots stretched back to the early centuries of the Christian era and whose fibres were tightly twined round the national life. The heart of the tree was architecture, and that art furnished the life-giving sap to the trunk and branches. This fact is fully recognised by the author, who in his preface, and in the first half of the book, practically devotes himself to the consideration of its development. This is all the more gratifying from the fact that Sir Walter Armstrong, as Director of the National Gallery of Ireland, might have been expected to somewhat minimise the pre-eminence of architecture. Fortunately he was saved from any such obliquity of vision by the possession of considerable knowledge of that art. Indeed, his opinions, although offered in such a modest phrase as "The connection between Early Norman architecture and that of the Saxons was probably less slight than is usually supposed," are worthy of consideration. The chapters are written in the form of essays dealing with the particular period or form of art under discussion, and are full of interest and suggestion, being very different from the more painstaking compilation that might have been excused as coming from an authority on one special branch. The chapters on painting show the various periods and productions practically from the advent of Holbein to our own day. The illustrations, combined with those on sculpture and "Certain Minor Arts," and, above all, the architectural photographs and drawings, show what a goodly heritage falls to the lot of every one born in these isles. The future offers hope of being worthy of its great past. Sir W. Armstrong proudly asks, "Has any people ever drawn itself more rapidly out of a non-artistic morass than the younger English and Scottish architects out of the chaos of nonsense building which prevailed here twenty—or even ten—years ago?" The volume is no doubt intended for perusal by non-architects, and it is well that they should read this encouraging message early in the book, and so feel a greater confidence and pride in contemporary architecture than seems to be general.

COMPETITIONS.

THE competition for the extension of Grimsby town hall has elicited fifty-one designs, which are now on view, but are scarcely worth a long journey to see. The assessor, Sir Alfred Gelder, has awarded the first place to Messrs. Eade, Johns & Browne, of Ipswich, the second to Messrs. Withers & Meredith, of London, and the third to Messrs. Rigby, Oliver & Phipps, of Manchester; but the Town Council has not approved the award as regards the payment of the third premium, on the ground that the authors' estimate too far exceeds the sum stipulated in the instructions. The third design would certainly not cost more than some others which, in the reports of their authors, are estimated at 26,000*l.* and a trifle over.

Messrs. Appleyard & Quiggin, architects, Liverpool, have been placed first in a competition organised by the Urban District Council of Waterloo-with-Seaforth, near Liverpool, for proposed Council schools in Crosby Road North, Waterloo, and Rawson Road, Seaforth. The assessors were Mr. P. S. Worthington, M.A., F.R.I.B.A., of Manchester, and Mr. Herbert T. Buckland, Birmingham.

THE competition for new secondary school at Whitby has been decided, and in accordance with the recommendation of the assessor, Mr. Paul Waterhouse, the first place has been awarded and the appointment as architects given to Messrs. Thomson & Bristow, of London. The second place, with premium of twenty guineas, has been obtained by Mr. R. W. Owen, of Liverpool; and the third place, with premium of ten guineas, by Messrs. Oliver, Leeson & Wood, of Newcastle-upon-Tyne. A very large number of drawings were submitted in the competition.

OUR CONTEMPORARIES FROM OVER-SEAS

THE *American Architect* has a Gothic number, the principal illustrations being of the reconstruction of the church of St. Vincent Ferrer, on Lexington Avenue, New York, a Catholic church for which Messrs. Allen & Collens and Mr. James W. O'Connor are associated as architects. The design is described as "following as closely as possible the best examples of the French Gothic," but reminds us of the Votiv-Kirche at Vienna more than anything we have seen in France. Mr. Collens writes an article on "The Grotesque in Gothic Ornament," illustrated chiefly by examples from the Union Theological Seminary, New York. The view of old Italian architecture is this week a detail of Lucca Cathedral, to keep up the Gothic *cachet*.

Deutsche Bauzeitung illustrates a country house at Barmen by Messrs. Albert Schulte & Volmer, and gives us an account of a fine example of town planning from the "Architectural History of Carlsruhe, 1715-1870," quite a subject for Professor Adshead, in his new school of Civic Design. Still on the same topic is an account of various schemes for the improvement of the lay-out of Paris. An interesting article, illustrated, is a description of a trip from the Dolomites to Venice, by Professor W. Manchot.

La Construction Moderne reproduces some of the remarkable and careful drawings made by M. Adolphe Thiers of the interesting church of SS. Sergius and Bacchus at Constantinople, the plan of which, with its axial variation of the dome and enclosing square, is very striking and curious. Our contemporary's remaining illustrations are of a villa at Mar-del-Plata, near Buenos Ayres, which we hope no one will copy over here. The series of articles on perspective drawing with a home-made trammel is concluded.

Het Huis continues its account of the Wallachian almshouse at Amsterdam, with further illustrations. Deventer and its history are described in an article which is to be continued, and illustrations are given from old engravings and photographs of its seventeenth-century aspect.

Correspondence

[*The Editor will not be responsible for the opinions expressed by Correspondents.*]

The People's Budget.

SIR,—Mr. Kemp in his letter to you of last Friday has touched the point which is generally missed: interfere with the landowner, and you interfere with trade. This is emphatically the case in the building trade, and if you touch the pocket of the employer, you still further touch the pocket of the employé. A member of Parliament, who is but a cog in the political wheel, may not comprehend this, but the British working man will if you point it out.—Yours, &c.,

P. B.

GENERAL.

Mr. Henry Brett, of Auckland, New Zealand, who is now in London as one of the Imperial Press delegates, has decided to present to the Corporation of Auckland a new organ for the town hall at a cost exceeding 6,000*l.* This enormous instrument is to be built at the works of Norman & Beard, Ltd., and is to be shipped to New Zealand at the latter part of next year.

Mr. G. Fellowes Prynne, F.R.I.B.A., has presented a report on the condition of the old church of St. Mary, Plympton. He states:—"There are several cracks in the tower which time will naturally widen; part of the parapet of the tower bulges out, one of the pinnacles is considerably out of perpendicular, and the top of another needs attention. The gutters and lead work of the roof require repair to prevent leakage in wet weather. There is also much necessary work required to be done to the interior." The approximate estimate of cost is:—Tower, 450*l.*; exterior of church walls and roof, 50*l.*; lightning conductor, 25*l.* It has been unanimously agreed that a committee will take steps to carry out the work proposed by Mr. Prynne.

FORTHCOMING EVENTS.

Saturday, September 25.

Institution of County and Municipal Engineers: Eastern District Meeting at Lincoln.

Monday, September 27.

Architectural Association: School of Architecture, Winter Term begins.

Iron and Steel Institute: Autumn Meeting in London September 27 to October 1.

Monday, October 4.

Royal Academy: Course of six Lectures on "Chemistry" by Professor A. H. Church, D.Sc., M.A., F.R.S., opens. Subject: "Paper, Canvas, Panel, and other grounds."

Society of Engineers: Meeting in Room 18 Caxton Hall, Westminster. Paper on "The Status of the Engineering Profession," by Mr. G. Allan Thomas.

Wednesday, October 6.

Institution of Sanitary Engineers: Meeting at Caxton Hall. Paper on "The Present Position of the Sewage Disposal Question" by Mr. W. J. Dibdin, F.I.C.

EXHIBITION OF STUDENTS' WORK, L.C.C. CENTRAL SCHOOL OF ARTS AND CRAFTS.

WITHOUT knowing the class and capabilities of the students it is difficult to appraise the value of the instruction given in any school. The results attained depend not only on the ability of the masters to teach, but on the aptitude of the pupils to learn and of their previous knowledge when they commence a course of instruction. In any exhibition of students' work one naturally expects to see the best that the school can produce, particularly when the amount of work shown is strictly limited in extent, as is the case in the present instance.

The most striking point about the exhibition of students' work at the London County Council Central School of Arts and Crafts is the inequality of the level of achievement that is reached in different subjects. While in some departments excellent work is shown, in others the standard is remarkably low, when one considers that all students at the Central School are presumably intending to earn their living at the particular art or craft which they are there learning. On the other hand, we must remember that the L.C.C. Central School has not very long been housed in its present home, and it is possible that with the change of location there has been a lack of continuity in the individual students whose work is now exhibited.

Directing our attention first to the School of Architecture and the Building Crafts, which, by the way, is held only in the evening, as appears from the prospectus of the School, we find a very low standard of excellence. We take it that we may understand the work of Mr. S. HOWARD JONES to be representative of the high-water mark of the School of Architecture and his design for a seaside house as the most important work exhibited. The aspects of the various fronts of the house are W.N.W., N.N.E., E.S.E., and S.S.W. The designer, to our mind, has gone hopelessly astray in respect of the vitally important question of aspect, for even though a seaside house may presumably be chiefly used in the summer time, we scarcely have any English summer in which the sun is altogether to be avoided; and as the sea-view is W.N.W. of the house, it must be supposed that the house is to be built in a "bracing" locality. Mr. JONES lights the drawing-room from the W.N.W. and N.N.E., the dining-room from W.N.W., about the worst possible aspect, for by help of a bay window a considerable amount of due West light is obtained, so that what sunshine the room does receive is from the low and glaring Western rays, which are so unpleasant at dinner-time. The day nursery has its light from E.S.E. and S.S.W., the night nursery S.S.W., also the worst possible for children who go to bed early. All the other bedrooms face either W.N.W. or N.N.E.

The next point in which we think the designer has erred is the sizes of his rooms. The drawing-room is 18 feet by 30 feet; billiard-room, 26 feet by 20 feet; study, 15 feet by 14 feet; and those who live in these rooms have to take their meals in a dining-room 16 feet by 18 feet, with a fireplace of full projection still further reducing the width of 16 feet. That the house is not a small one will be understood from the sizes of the "reception" rooms, and is still further illustrated by the provision of a servants' hall 18 feet by 13 feet. The site was not a particularly easy one to deal with, as not only was the sea-view in an awkward aspect, but there is a considerable rise from South to North, so that the principal entrance is on the first floor.

The elevations are treated in a seventeenth-century mullioned window type of architecture, in which it is not easy to go wrong, but Mr. JONES has managed to include an anachronism in a "Wilton" window, though he has had the good sense to modify its incongruity to some extent by diverting it of its usual trimmings.

A design for a gardener's cottage by Mr. G. A. BRYAN, though a less ambitious subject, is a better performance. The demand for a kitchen, sitting-room, large scullery with bath, and a potting shed on the ground floor, render easy the provision of four good bedrooms above and a liveable house and picturesque withal is the result.

Two designs for the elevation of a terrace of nine houses are not very remarkable for excellence, although Mr. F. G. MITCHELL'S, in what we may call the L.C.C. style, is not altogether devoid of merit.

The measured drawings and water-colour sketches are of a very low quality, and their authors have a long way to go before they reach the standard, say, of honourable mention in the competition for the Pugin Studentship.

Very good is the system adopted in the School for teaching the nature of stresses and strains and their methods of calculation. Working models with spring balances not only make quite clear the direction of the stresses, but enable the students to check by ocular demonstration the results at which they arrive by calculation.

The School of Cabinet Work and Furniture is an evening department, and the work exhibited includes both design and craftsmanship. The designs for furniture are wanting in originality and chiefly feeble copies more or less closely following old examples principally of eighteenth-century work. The executed work is apparently that of young men who are, or should be, apprentices, and far below the standard of a journeyman cabinet maker in joinery, though good in inlay and veneering. This is rather putting the cart before the horse; excellence of surface decoration will not compensate for doors that do not fit and drawers that do not run in high-class cabinet work. Some of the articles of furniture produced, such as the veneered and inlaid cabinet by Mr. H. W. BRANDT,

Digitized by Google

would be admirable if the joinery work were characterised by more precision.

It is not quite clear from the exhibition how much work comes from the evening School of Silversmiths' Work and Allied Crafts, but the prospectus includes quite a large range of subjects, under which may be classed some of the best work to be seen. Some copper-plate engravings after ALBERT DURER are excellent; the jewellery, much of which is the work of women students, enamelling and silversmithing are of a very high order both in design and in workmanship, and quite good enough to be marketable, which of course is the goal at which we may suppose the Central School of Arts and Crafts to aim.

Another department which shows work that reaches a high standard is the School of Book Production, which includes bookbinding, typography, black-and-white illustration, lithography, miniature painting and etching, in all of which sections there is to be seen some very high-class work. The exhibition does not make it clear how much of the credit for this is to be given to the evening school and how much to the day classes for black-and-white and other illustration, lithography, miniature painting and etching. Indeed, the exhibition as a whole is very much lacking in arrangement and method. It is not clear to what section of the Central School the various exhibits belong. The work of the Royal Female School of Art is merged, we might say submerged, in the general work of the institution, and possibly the L.C.C. school gets some of the credit that ought properly to belong to the absorbed organisation under the care of Miss ROSE E. WELBY. Certainly very much of the best work in the exhibition has been produced by women students. This is particularly manifest not only in jewellery work but in painted pottery and the especially feminine craft of needlework. We cannot but credit Miss WELBY's pupils with much of this excellence, for the design is good as well as the execution.

Stained glass is the chief product, if the exhibition is to be taken as a criterion, of the School of Stained-glass Work, Mosaic and Decorative Painting. Here the cartoons in monochrome are the best feature, though in some instances sufficient thought seems not to have been given to the leading. The executed examples we think are poor in colour, though the drawing is fair and the leading good. We imagine it must be rather difficult to teach stained-glass work in an evening school. It is hard enough for an expert glass painter to work by artificial light, but for novices to estimate the effect of daylight on translucent glass from its appearance under any form of artificial light must be almost hopeless.

The examples of figure modelling, we presume from life, are good, though the pose in some cases is rather theatrical.

Woodcarving is, to our mind, one of the weak developments of the Central School. The students do not seem to have learnt the first lesson of a woodcarver—to keep his tools sharp. They should be impressed with the desirability, for tyros in the craft, of spending more time in sharpening their tools than in cutting wood. The next lesson that the students of the Central School need to learn is that woodcarving is drawing in the solid with a cutting instrument, but requiring at least as much accuracy of line as if it were done with a pencil on paper, than which it is naturally far more difficult. Anyone can cut wood, but cutting wood is not carving. The students in the woodcarving classes should be obliged to spend a considerable portion of their time in drawing on paper and on the flat wood, and not until their drawing is fairly accurate should they be allowed to handle a chisel and mallet.

NOTES AND COMMENTS.

THE excellent work that is being done by the Committee for the Survey of the Memorials of Greater London is well attested by the publication of Vol. II. of the Survey of London, the eleventh publication of the committee. This deals with part of the parish of Chelsea, a parish that at present at any rate is so rich in memorials of Old London that one volume is not sufficient to record all that it contains worthy of the attention of the committee.

IT is well for London that there are a number of enthusiastic architects and lovers of the ancient art of London to constitute a goodly and efficient body of active members who are skilful with camera and pencil, learned and painstaking in the exploration of antiquarian lore, to gather together records of what still remains to us of the London of the past. Needless to say the memorials still existing cannot be expected to last for an indefinite period. The requirements of our modern life, the value of the land on which they stand, the effects of time and the danger of fire are all elements threatening their destruction. It is important therefore that all who love London should lend assistance to the work of the committee, financially as annual subscribers of one guinea or personally as active members, willing to give their time and their ability if such they can devote to the work with sufficient enthusiasm and quality to rank alongside the accomplishments of the present members.

A VERY good investment is the purchase at twenty-five shillings for those who are not at present subscribers of the latest publication of the committee. Cheyne Walk and Paradise Row from which the subjects in the present volume are mainly drawn are a mine of wealth to the student and the admirer of eighteenth century domestic work, and the photographs and measured drawings as well as the water-colour sketches contributed by the active members are so excellent in character and technique that artist and antiquarian alike cannot but derive both pleasure and profit from their possession and study. The records of the memorials as they stand are well supplemented by historical notes and reproductions of old illustrations.

BY the generosity of the Worshipful Company of Carpenters a course of ten public lectures on the Renaissance of Architecture in Italy is to be delivered at University College, London, by Mr. HALSEY RICARDO, on Tuesday evenings, commencing October 19. Tickets of admission will be issued without fee, but the lectures are intended for those who have already some knowledge of architecture. University College has long been noted for the excellence of the architectural lectures given by the able professors who have occupied its chairs, but the fees have been somewhat high, not in comparison with the value of the instruction given but for the pockets of those for whom they were intended. We do not doubt that Mr. RICARDO will worthily maintain the prestige of the College, and the absolutely gratuitous nature of the offer thus made by the Worshipful Company of Carpenters to the architectural students of London should ensure a grateful and appreciative response.

UNIVERSITY COLLEGE also offers in its evening classes instruction in design under Mr. CYRIL POWER, with Mr. LEONARD STOKES and Mr. ERNEST NEWTON, two of our ablest designers, as special visitors, who will set the subjects and criticise the designs. The fee for this excellent instruction is the merely nominal one of half a guinea for two terms. For those who are novices in design there is a junior design class, embracing also a course of lectures on construction and planning, for which the same nominal fee only is charged. Thanks to the Carpenters' Company, University College is now able to meet the rate-supported Polytechnics on their own ground of low fees, but unless we are very much mistaken it will never descend to the level of Polytechnic teaching in architecture, but always maintain the high tradition of its past. We would advise all architectural students who may be tempted by the low charges of the Polytechnics to turn their steps to Gower Street.

THE report of the Committee on Ancient Earthworks and Fortified Enclosures points out that the Government has taken up, through the medium of Royal Commissions, part of the work that the committee initiated, the recording of ancient earthworks and pre-Roman remains. It is to the credit of the committee that its labours have brought about so much recognition of the importance of

Digitized by Google

the subject as to justify it in engaging the attention of a Royal Commission. It is to be expected that the Government will not stop at records, but take such further steps as may be necessary for the preservation of the remains that are still in existence. The committee's report tells us of what in the past year has been effected, largely, no doubt, through their influence and persuasion in the way of preservation, and also what unfortunately has occurred in the way of destruction.

IN the former category we find Maiden Castle, Dorset; Thetford Castle, Meadow and Hill, Norfolk; Stokeleigh Camp, Somerset; White Barrow, near Tilshead, Wilts; Selsea, Sussex; Epping Forest landmarks; Pendinas Camp, Cardiganshire. On the other side of the ledger we have evidence that damage has been done which Government influence, properly directed, might have prevented. The Commissioners of Woods and Forests have leased for quarrying a hill fortress at Penmaenmawr, and the Territorials have practised entrenchment at Conway.

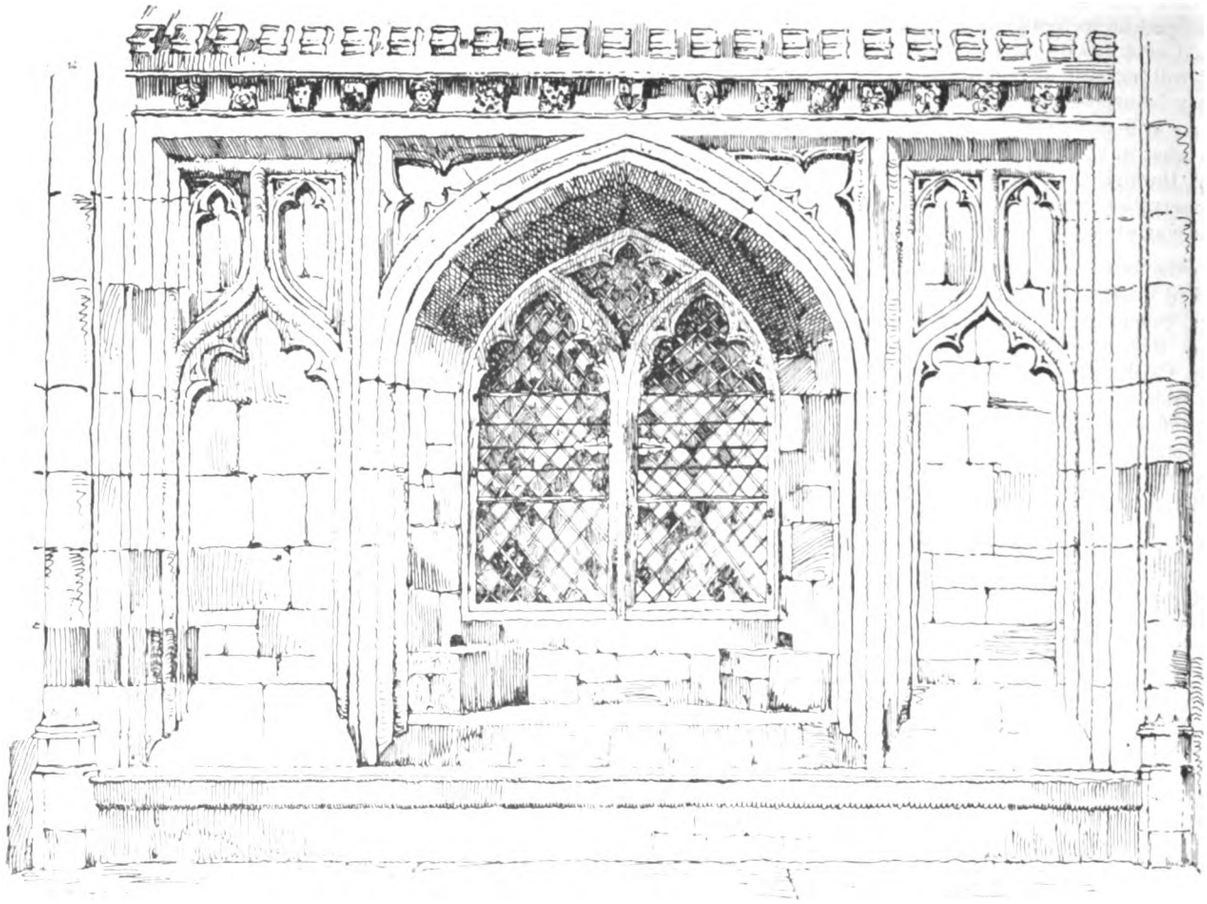
ANOTHER branch of the committee's work is exploration, and in this direction several localities have been investigated, in many instances with the co-operation of local Archæological Societies. The results of the explorations are described in the report or reference made to the bibliography of the subject, in which such results are more fully recorded.

THE annual report of the Sheffield Society of Architects and Surveyors contains the address of the President, Mr. W. C. FENTON, abstracts of lectures delivered during the past session, and the announcement, for the work of the forthcoming session, of lectures by Professor F. M. SIMPSON, on "Architectural Developments during Victoria's Reign"; by NIGEL BOND, on "The Aims and Work of the National Trust"; by EDWARD HOLMES, "Notes on the Development of Town Planning"; by SYDNEY D. KITSON, on "An Eighteenth-century Architect: Carr, of York"; by C. B. HOWDILL, on "Stained Glass." The Treasurer's statement of accounts for the year shows that the balance in bank at the beginning of the year, 45*l.* 0*s.* 4*d.*, has been slightly reduced to 41*l.* 6*s.* 2*d.*, but there appears to be an amount of 7*l.* 10*s.* 5*d.* due from guarantors to the Society for the Department of Architecture, so that the finances seem to be in a satisfactory condition.

"A BEAUTIFUL WORLD" is the title of the occasional journal of the Society for Checking the Abuses of Public Advertising, and to maintain the beauty of a beautiful world is the object the Society has in view. That it is in a measure attaining its object is shown by the passing of the Bill it promoted into law as the "Advertisements Regulation Act, 1907." This Act gives power to local authorities to frame bye-laws with a view to preventing or reducing the disfigurement, by advertisements, of (1) beautiful landscape, (2) pleasure promenades and public parks.

THE difficulty of framing bye-laws under the Act that would be satisfactory is the reason for the little that the Act has already done in improvement of the conditions of advertisement, but it is pleasant to know that the bye-laws drawn up by the County Councils of Westmorland and Somerset, and by the Corporation of Exeter, have been approved by the Secretary of State, and that the draft of the District Council of Barnes is under consideration. The London County Council in July last invited the several Metropolitan Borough Councils to submit schedules of parks and pleasure promenades within their jurisdiction with a view to protecting them by bye-laws under the Act. So that progress is being made in bringing to bear the powers with which local governing bodies are invested. The education of public opinion is part of the programme of the Society that needs continual pressure, but we doubt not that in course of time we shall be spared much of the insult to our feelings and injury to our health and temper that blatant advertisements in public places now inflicts.

DISCOVERIES AT THE GUILDHALL.



WIDESPREAD interest has been aroused by the discovery of two blocked-up windows in the west end of the Guildhall, near the gallery. Mr. SYDNEY PERKS, F.S.A., F.R.I.B.A., the City Surveyor, has for some time past been carrying out a systematic clean-up, and last week he was authorised to examine a portion of the south wall he diagnosed as containing hid treasure, but which appeared to be mere filling-in. When this was removed a complete two-light Gothic window was revealed, 9 feet 6 inches in height and 6 feet 6 inches in width, the depth from the inside wall to the glass being some 3 feet. Each of the sections has an iron latch and swings on strong hinges. The stonework round it contains iron rests for supporting shutters, and on either side at the bottom are blocks of stone. The inference that other similar windows might also be bricked-in proved correct, for on the following day a second was discovered in the wall immediately opposite. This latter was in a worse state of preservation, for the mullion was broken, and it was without glass. It is generally believed that these windows are part of the Guildhall that was commenced in 1411.

The tradition that the City of London has had its civic life focussed on to the present site of the Guildhall since the reign of EDWARD THE CONFESSOR is not one that will bear investigation. Its chief grounds are that arms of that monarch appear on bosses in the crypt and porch. But these cannot possibly be carving of contemporary date, and at most point to the possible existence of a belief when the later hall was built in the reign of HENRY VI. that a similar building may have occupied the site over three centuries earlier. The unimpeachable records of the Hustings Rolls contain references to meetings at the Guildhall from 1269 onwards. JOHN PRICE, who prepared an elaborate official descriptive account of the building over twenty years ago, says:—

"The entries are sufficient to illustrate the existence of a Guildhall in the thirteenth century, and to show that to all intents and purposes the uses to which the early building were devoted have remained unchanged to the present day; and, further, they go to prove that the site of the hall is in close association with that upon which the first one stood. They prove conclusively that, while the hall has passed through sundry transitions—been altered, added to, and enlarged from time to time, no evidence is forthcoming to show that the Guildhall of ancient times was ever situated in any other part of London than where it at present stands. The enlargement of this ancient building appears to have taken place in the year 1326, and in the mayoralty of Richard de Breton, Britain, or Betoyne. At this time a grant of timber and lead appears to have been made towards the works at the hall and chapel."

But the indisputable history of the building commences from 1411, when, in the words of an alderman elected eighty years later, "Ye Guylde halle of Lodon begon to be newe edyfied, and of an olde and lytell cotage made into a fayre and goodly house as it nowe apperyth." The manner in which the requisite funds were obtained was not of a kind that would be now tolerated. From 1412 till 1439 the Court of Common Council exacted extra fees of 2*s.* 6*d.* and 3*s.* 4*d.* from all apprentices at the beginning and end of their apprenticeship; for every will an extra fee of at least 6*s.* 8*d.* The fines imposed in the Mayor's Court were devoted to the work, and also fees from deeds, charters, letters patent, and so on. HENRY V. granted to the City a free passage for four boats by water and four carts by land, carrying building materials. Contributions were continually made by leading citizens like RICHARD WHITTINGTON, whose executors gave 35*l.* to the paving of the great hall with Purbeck stone and glazed some windows. Seventy years later WILLIAM HARIOT, Draper and Mayor, gave 40*l.* for the provision of two handsome louvres in the roof. These show prominently in the old views of London. The chronicle of the Grey Friars quaintly records, "Thys yere in September the King went to Callys with a grete armé agaynst France, but the pece was made with-owte battelle.

NEWLY DISCOVERED WINDOW AT THE GUILDHALL, LONDON. FROM A SKETCH BY ADRIAN HARDMAN.

And the Qwenys moder dicessyd. And the lovers sett up on the gelde hall of London." The Company of Masons gave a quantity of Kentish rag-stone, and the Linemen likewise contributed in kind.

By the time of the Great Fire of 1666 the various buildings had become of considerable extent. In that conflagration the carcase of the Hall itself, with a portion of its roof, was left, but the various surrounding offices and apartments were destroyed. Curiously this loss is ignored by both PEPYS and EVELYN. However, a contemporary diarist of no mean descriptive powers records:—"That night (Tuesday, September 4) the sight of Guildhall was a fearful spectacle, which stood the whole body of it together in view for several hours together after the Fire had taken it, without flames (I suppose because the timber was of such solid oake), in a bright shining coale, as if it had been a palace of gold or a great building of burnished brass." Although the then Lord Mayor is regarded with undisguised contempt by PEPYS for his inability to rise to the crisis, he lost no time in setting about the re-erection of the Guildhall. An examination was made by WREN, who later designed a supposedly temporary flat-roof, though it endured for two centuries. The rubbish was ordered to be removed, and it was ordered "That Mr. MILLS and the Citty workemen doe speedily as can be done prepare conveniencys within the ruines of the Guildhall, to keepe all the Courts there in the places they were antiently kept." In December of that year THOMAS JORDAN, the city mason, was paid twenty pounds on account for the stonework in connection with the rebuilding. It was also at once decided that a new street, 36 feet broad, to be called King Street, should be cut from the Guildhall to Cheapside, and another from Cheapside to Newgate. The reconstruction of the Guildhall, together with the buildings connected with it, involved a total cost of 34,776*l.* 5*s.* It was carried out on a grand scale and aroused admiration. According to RICHARD BLOOME (1670-93), "The rooms, courts, and offices are appropriated to the same plan wherein they were kept formerly, but much more regular and loftier and more substantially built. The Great Hall being formerly in height, as to the upright of the walls, not above 30 feet, which now are raised 20 feet higher on either side, and at both ends where there are fair windows and eight large windows on either side, of 16 feet high each window, where there were none before."

The history of the Guildhall during the eighteenth century is wrapped in obscurity. In 1785 GEORGE DANCE, R.A., prepared a design for enlarging the porch, and he also designed a startling façade. Shortly afterwards he incurred the displeasure of the Council. The following letter, sent by Mr. DANCE in 1792 to the Court of Common Council, is worthy of reprinting:—

I have executed the office of clerk of the works to the City of London for the space of twenty-five years, and about twenty years since I was induced on account of the increasing state of the City's business to apply to the committee of City lands to be allowed an assistant at my own expense. . . . I have made it a constant rule, either by myself or Mr. Peacock, to survey all new buildings immediately on their being covered in, and before the internal walls were covered, which is the usual mode of surveyors to public bodies as well as individuals who let ground to build on, and for which is allowed a fee of one guinea per house. . . . Whatever errors or neglects may be imputed to me, when I refer to my own conscience I can sincerely say I have never been influenced by corrupt motives, and when the fullest inquiry shall have been made into my conduct I hope and trust it will appear so to you.

The many alterations carried out by Sir HORACE JONES, the City Architect in 1864, show what can be done by one who approaches his work with a deep respect for the past. Particularly noteworthy is the roof of elaborate open timber-work. The same spirit has animated the custodians of the buildings since that time up to the present day. Mr. SYDNEY PERKS, the City Surveyor, has within the past few months been successful in showing much of the old stonework which was previously obscured by paint and plaster. His painstaking investigations have been suitably rewarded by the discovery of the two windows already mentioned, one of which is reproduced in our drawing.

ARCHITECTURE: ITS TRUE PRINCIPLES.—XIX.

By R. OWEN ALLSOP.

SUBORDINATE MASSES.

THE value of geometrical design in arranging subordinate masses is that by mere rectangularity and parallelism the one part refers (is related harmoniously) to the whole even without the necessity of actually connecting links—that is to say, two building masses near together, either at right angles or parallel, indicate, *prima facie*, connection of the two. Here again we see that the effect arises directly from the plan. Masses not parallel or rectangularly placed have no geometrical connection, real or implied; for the most evident geometrical relation is parallelism or rectangularity. That is to say, the edges of the cube are right-angles and the sides parallel. Anything therefore arranged in the same plane or axis or at a right angle seems to imply direct reference from one mass to the other. The architect, therefore, who is master over the site (arranges a geometrical plan irrespective of ground) is acting on sound principles; and it may be generally laid down as a law for planning that unless practical service demands some other arrangement the square, the axis, and contrasting axis should override the site irregularities. At the same time the following of the natural trend of unavoidable irregularity in the site may bring about of itself varied and interesting compositions. All great works, however, are dominant of the site. Every building requires sufficient ground-space, just as no man can be great who is closely linked, mentally and bodily, to neighbours on either side.

We may, therefore, first consider the arrangement of masses of building on free, unrestricted sites. The first essential of the monumental building is the maintenance of the axial line in the plan. This materialises the geometrical expression of the plan, and ensures symmetry, employing here the term "symmetry" in the sense of that which is well-proportioned and suited to its purpose.

The most reasonable view of the question of pure bi-symmetry—meaning a mathematically equal arrangement about an axis or point—is that there should be this

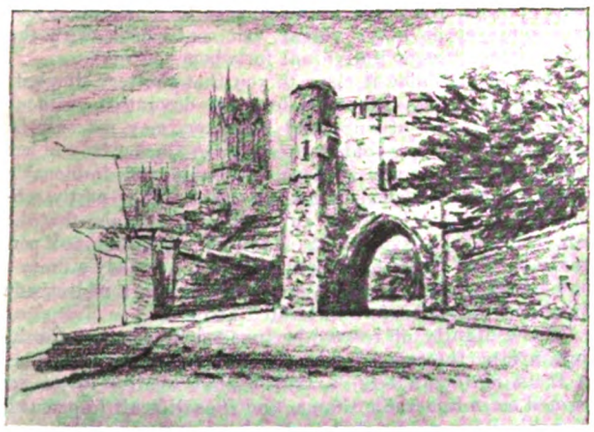

FIG. 41.—THE POTTERGATE, LINCOLN.

symmetry in the detail, but *balance* in larger things. Thus leaves are practically symmetrical, but trees are balanced as to mass. In nature, and pictorial representations of nature, as perhaps observable in fig. 41, tree masses may be frequently noticed to balance an architectural composition. If we extend our inquiry into the animal kingdom we see, generally, one plane of symmetry, usually vertical, with one symmetrical elevation, the front and back as correlative to this. This is the cathedral system—as a rule the symmetrical west end, the asymmetrical side elevation with the great plane of symmetry formed by a vertical section in the long axis through the centre of nave and choir. Who would wish for an exact bi-symmetrical side elevation to Ely or Durham or any of our old cathedrals?

The question here raised is an important one and may well be considered before any attempt is made to find any useful suggestions or rules respecting composition of irregular masses.

The point may be put in the form of an inquiry, as follows:—Why should there be exact symmetry on the western face and not on the side faces of the cathedral? It might very reasonably be advanced that inasmuch as we are pleased with the one aspect—its symmetry—we should be displeased with the other.

We are aware of a sense that it would please us as little to see a horse with a head each end as a cathedral with exactly balancing towers at either end. We may evidently well push on our inquiry respecting geometrical and symmetrical architecture if it can afford us some definite answer to this question.

It is necessary to carefully distinguish between the various classes of symmetry, particularly the distinction between the symmetrical elevation and a symmetrical plane. Apparently, the human figure is symmetrical viewed before, and behind as a natural consequence. The two things have points of separate and distinct import. Thus the plane of symmetry supposes such a bisection of an object, that placing the one half on a mirror, the reflection exactly completes the figure. Thus a swan bisected through the head, neck and back vertically affords a plane of symmetry. It is the symmetry arising from the axial plan. The other kind of symmetry is the plan itself mathematically and equally repeated on either side of the axis. This latter—the plan set up vertically on the cross, heart, anchor, Greek temple, cube or parallelogram—is the symmetry of the cathedral front, supposing the two end towers to be similar.

The general rule evidenced by example seems to be:—Exact symmetry in small parts, but not in large (long) ones. The sense of such an arrangement may be best seen by exaggerating a case, reducing it to an absurdity. Imagine a building with a façade five miles long. What would be the value of exact symmetry—equal halves about a centre—in such an elevation? It is certain that no eye would ever see the symmetry unless it were that of the hovering hawk. Therefore, whilst the effect of symmetry is utterly lost and useless for effect, it should be noted that the whole of the façade *suffers* (the only appropriate term) from the existence of this useless symmetry. Every part of the composition is affected by this reduplication of parts to form a whole equal-sided design. We thus arrive at the main objection to uncalled-for bi-symmetry; that in order to produce it everything else in the composition must be sacrificed, and it should be observed that this cause is altogether independent of the fact that it is inconceivable how the demands of practical service can be met by this mechanical doubling of a design about a central point.

Symmetry, then, in the popular sense, is not only not called for in the main (long) mass of a large building, but it is æsthetically offensive, without any value and antagonistic to practical service. Wherever it is found it is bad, as indicating a lack of skill and appreciation of the fitness of things either for beautiful effect or practical ends. It is never pleasing. It is never found in really great works of large extent covering large ground area. It is a vice originating with the elevationist who, with no imagination, being unable to think in perspective, symmetrises speciously a half-furlong of building to a microscopic scale, and is pleased with his production of an effect that no mortal eye will ever behold and still less ever comprehend. Such a person must regret that man is not double-hinged at the toes, so that the recumbent effigy would be "symmetrical." The right use of symmetrical design must be sought, for otherwise it is quite easy to prove that that which is symmetrical is bad art if not positively mechanical and wanting in any evidence of brain power.

Symmetry in the part and in the axis must ever be the guide. We see no symmetry (so-called) in the side elevation of the cathedral, but we do find it again in the transept end, in the central gable and side turrets and other duplicated wings; and here it should be observed that the symmetry arises from the symmetrical plane crossing the main axis of the composition. Planes of symmetry are

Digitized by Google

what is required, and these need axes in the plan—symmetry of the part and rigid symmetry or careful balance in the detail.

The ends of planes of symmetry should finish in visual (elevational) symmetry. This may be a rule. It is evidently a guide not to be lightly discarded. The equal-sided end to the axis emphasises the actual axis, confirms its existence. This we want. We desire to know that the main axes exist; they are potent for good in bringing about a unity of effect.

Over-studied "symmetry" destroys character. There is always something of the commonplace in the long (main) composition of centre and wings, of dome and flanking turrets. We seem always to have seen much the same idea before. The asymmetrical composition gains in individuality. It opens up endless combinations for character-formation. There is this much about the long-extended symmetrical façade, that it never gives the effect intended, because any dominant tower or other feature—part of the building, but not along the same front—destroys at once the appearance sought (one imagines) to be given. After all, the reliance on symmetry (so-called) for architectural effect may be compared to a man respecting main laws and behaving in accordance with generally required conditions, but lacking in qualities making for active individual excellence.

Two planes of symmetry, as in a square plan (either actually such or comprising four equal arms) are never pleasing except in towers and monuments, which latter can scarcely be called architecture, not having the necessary interior parts, having no true walls. Such an equal-sided composition always suggests a monument, even, indeed, when it is in reality a true tower, such as we understand this to be. It seems essential for effect that the plan of a building should have a length and a breadth—that is, be far removed from the square.

In place, then, of symmetry as a thing of equal-sided face, we should do well to think more of planes of symmetry and of the geometrical axis and the necessity for pure bi-symmetry as stops to this axis and to all minor axes that may cut the major. This is following the spirit of natural law, and until man is double-ended, or has nose and other features as well at the back as at the front of his head, we need not worry about what is not required—equality of halves in lengthy façades.

There must be some other reason that causes our aversion to forced symmetry, and to at least view with suspicion the too equal-sided work of architecture *on a large scale*. This latter is an important proviso. What is suitable in a small building, that we can easily take in at one view, is not suitable for an extensive work. The cause that we have suggested is doubtless that the several parts of an edifice rarely correspond in their purposes. A central hall and a grand staircase may bisect two series of apartments of equal importance. This seems to be a suitable subject for what might be termed pure symmetry. But taking the cathedral we find a different value is to be set on the nave, the choir crossing and lady chapel and other features. In such case no reasonable shadow of excuse exists for side divisions of equal value.

(To be continued.)

DECORATIVE ART FOR THE MASSES.*

THE subject which I have chosen for my address covers an area of thought and action almost too comprehensive for a short lecture. As I think the matter over, I am constrained to avoid puzzling you with too many details in history or the practice of the purely decorative arts. As far as possible, I shall hope to be practical, at the same time keeping a high standard before myself as well as before you on a subject which is not only of momentary importance, but which must exercise upon future generations influences either good or evil.

That the trade, or, as I prefer to call it, the art of the house painter and decorator in its broadest sense bears with it great responsibility goes without saying, because it deals with matters of every-day concern as applied to utility, permanence, as well as far-reaching lessons on æsthetics.

By the judicious and tasteful exercise of your calling you must exercise influence upon the masses, by a dignified reserve which you can exhibit and inculcate among countless numbers of people more or less ignorant of the highest qualities of pictorial art.

The range of your influence is enormous, even extending from the peasant's cottage to the prince's palace. Granting it to be so you will not tell me that I exaggerate the responsibility of your calling.

In every art, from literature to the humblest handicraft, proportion and reserve play prominent parts. In the decorative arts each section, from the simplest to the most complicated, should be the best of its kind. What is applicable and essential to the needs of one section of a community is not so to another, yet "simplicity" should be the "leit motif" of the most elaborate as well as of the most immature decoration. "Exuberance" has its merits as "plainness" has; each is consistent in its own degree of environment. Perhaps I should define what I mean by the maintenance of simplicity or plainness, even when combined with exuberance. I mean that the underlying structure should never be lost sight of, that the roots of any design in form or in colour should never be masked by or buried under a complexity of ornament. Decoration can be plain and simple without being dull or uninteresting. It can be exuberant also without loss of reserve and dignity.

If I have made myself understood, you will recognise that while I accept elaboration and splendour of design, as well as detail, to be admissive, they are only to be judged so when in agreement with the object they are called on to fulfil or illustrate, and are in harmony with the "status" or "class" of the people they accommodate.

As in life, so in all the arts, ostentation and incongruence are vulgar. By vulgar I mean something pretentious, seeming to be what it is not, to emulate a sphere outside the boundaries of consistent classification.

No decoration should appear to have cost more money than it has done. Directly it does so it is open to the stigma of ostentation, hence is vulgar.

You have many grades, each distinct, to work in and for, many classes to satisfy, small as well as big purses to provide for, from the peasant's cottage to the prince's palace. To supply these numerous grades you must exercise your judgment, so that your work shall appear to grow out of the grade and yet be never vulgar, but conformable with the status of the class or individual for whom you work.

Here let me make it clear to you that the very simplest, most severe, even immature form of decoration, without applied ornament of any kind whatever, may not only be extremely interesting, but impressive. A Quaker lady in her grey satin is, among a blaze of jewels and fashionable women, a distinguished, dignified object. It is partly contrast which makes her so to appear, but partly also that the pure colour is a symbol of a reticent and dignified personality. Let there be placed upon such a lady's dress a sham jewel, or a discordant note of colour in a ribbon, and the charming vision is adulterated at once.

If the dignity of reserve be invaded by sham or the inappropriate, the area of vulgarity is immediately reached.

It is, unfortunately, a truism that we live in an age devoted to innumerable shams, and it is difficult to persuade the unthinking public that their adoption is unnecessary and unavailing, that perfect sincerity, even to severity, can never be vulgar, and may always be impressive.

This preamble clears our ground. You will now recognise that "fitness," "propriety," "proportion," and "reserve" are the articles of faith which it is my desire to inculcate when necessary, and to promote and encourage wherever they are accepted.

Fashion is a deceptive goddess; in no sense is she one of the Olympian deities. Insincere, unstable, full of paradox, alive to innovations, loaded with inconsistencies, she is defiant towards every—even the simplest—law of æsthetics, "fitness."

She leans towards monstrous vulgarities and sows vitiated taste, irrecoverably too often. It is not from the moment, or from passing moods of fashion that we should find our monitors, but from the art of ages, purified by time, accepted by universal experience, that has proved it right to the maintenance of masterpieces of good taste, from which, without copying them, we may tune our own instrument to an essential scale and tone, and find that "style" is the expression of his best in all the arts of man.

* Abstract of a lecture by Sir William B. Richmond, R.A., delivered at Sheffield before the National Association of Master House Painters and Decorators.

Digitized by Google

You may ask me what I mean by "style." I mean "proportionate selection," the abnegation of mere essentials, the presence of dignity, beauty, and reserve, the exclusion of unnecessary ornament such as does not grow out of structure, and the inclusion of ornament only where it will enhance the beauty and interest of structural necessities. This is a severe reservation. I give you an illustration of what I mean. Let us project our memories and imagination to an English dwelling of the sixteenth century, perhaps of earlier date—Anne Hathaway's dwelling at Stratford-on-Avon. Here is a well-known type of cottage of a great many which happily still stand unmolested by ruthless changes under a misnomer, progress, and compare it to the comfortless, dull-stupid, ill-built edifice of this progressive (?) age, erected to respond to the needs of a similar class of the community.

It is supplied with stone and brick foundations, solid, strong oak and elm framework and beams, lime-whited walls, furniture severe and strong in design and make, brick or stone, or oak floors, metal utensils in perfect taste. It is a dignified residence, snug and homely, a very type of the agricultural, noble England before our vast smoke-laden cities were in existence and a third part of England had been laid waste by blast furnaces, and handwork had been driven away by the ruthless thud of steam engines, and the unsympathetic, cold produce by machinery. In such a place we are in the presence of a dignified life, free from the "muck rake of wealth," where there is no ostentation or vulgarity; it is illustrating its purpose and in harmony with the modest income of its inhabitant.

Imagine this calm and dignified beauty improved by deal boards, a startling wall paper, a vulgar carpet, a modern firegrate, a slate roof. Should we not ask ourselves if our much vaunted civilisation and claims to scientific and practical progress are quite within the claims of truth? Shall we not ask ourselves whether we have not lost at least as much as we have gained? Our answer will, I think, be that in matters of good building, in many respects of comfort, certainly of beauty and dignity, perhaps also of health, we have more than enough to learn from the life and the artifices of the sixteenth century.

This is one point I lay before you. Now we go on a step further and to an increasingly difficult problem, an enormous population where good taste is practically non-existent, or so rarely as to be hardly noticeable. A great mass of people comprise the lower and upper strata of the middle class. This element, the product of an artificial civilisation, is the most difficult to modify or chasten. It stands badly in need of education in matters of good taste. The middle class of town-bred folk represents a new development; it is composed of possessors of a smattering of commercial education, a smattering of culture; it is a class where narrow views and self-interest are very prominent, where egotism is a faculty, and a narrow groove the chief funnel of restricted ideas, among which anything approaching good taste is too often conspicuous for its absence.

The agricultural peasant may be a boor; sometimes the town-bred middle-class man is a Philistine. The former may have chances of development; the latter is self-sufficient, self-occupied, and unelastic. It is this class which it is within your province and power to educate, but to do so, you and I, who may claim to teach, must have sifted problem after problem and determined what we mean by "fitness," and good taste must adhere to our principles, and when we teach be consistent and strong.

We must know what we like, what we know to be admirable before we can guide.

Again, may I impress upon you that the embellishment of a room, or a house, or a shop window, a church, or palace should not appear to have cost more than it actually has; if it does it is vulgar.

Therein is your difficulty, and as wealth increases facilities for vulgarity grow. As steam engines rotate more and more, the market will be growingly flooded with shams, and until good taste is taught with axioms as definite as arithmetic, and the teachers believed in, supply will equal demand for cheap and nasty, vulgar or glaring design, in preference to what is lasting, modest and beautiful. Setting aside the difficulties which the last paragraph has stated, and recurring to my original statement that you are artists, therefore you should be leaders, I will consider with you the decoration of a sitting-room of a small house of a rent, say, of 50*l*. to 100*l*. a year. The number of such is legion in every large town.

We will say you are called in to paint and generally furnish a room of such a dwelling. The wall-paper will probably be the first item. In nine cases out of ten, supposing you take a roll of wall-papers to your client to choose from, the chances are he will make choice of the worst, the most gaudy, and, at the same time, the cheapest, the most ostentatious appearance at the smallest cost. That will disconcert you. Presently you will be consulted as to curtains, blinds, carpets and furniture. The same difficulty will arise. Your client will tell you "he knows what he likes." That may be so. He may like bad grammar and bad English, but his doing so does not prove that either is correct or desirable.

This is a gentleman that stands badly in need of education. If you are strong through experience and well-earned conviction you may convince; if not, another monstrosity of a dwelling-room will be added to existing millions. For some reason a wall-paper is an undesirable comparison. If of best material and first-rate design it is expensive; good or bad, however, it is difficult to cleanse.

It may be the habitat for germs, harbouring in the old paste a decaying paper. There is disinclination to remove it. Too often, instead of being stripped, another paper is added. Thus a new system of germ is encouraged, and inhygienic deposits are deposited.

There are some excellent distempers which fix powder colour, are washable and permanent; the use of these I strongly advocate. Tints are now obtainable which can be brought into felicitous harmony. I would advise you to select the lightest tones. Under present conditions of the atmosphere of towns and cities, light rooms are essential on every account. It is true that dirt is more visible on light than on dark objects. The dirt is there, a sign that cleaning is needful. Surely it is better to see dirt than not. A visible evil is combatable; hidden, it is dangerous. On the whole, the most effective, healthiest, pleasantest to live in is a white room. There is no white so pure as lime; no product is so successful in the slaughter of offensive animal matter. Lime is cheap and efficient. Every coloured object, save dark ones in large masses, looks well upon white, which, in my opinion, is the safest of all tints to use in large quantities.

A very little ornament skilfully applied in pale and quiet tints will look precious on a white ground. White is the enemy of gloom; its relationship with dark and heavy tints is distant; it seems to ask for, almost demand, a scheme of colour reminding of delicate spring flowers. White is sensitive to every change of direct and reflected light; white walls will almost double the appearance of the area they environ. It is exhilarating to the nerves and a constant æsthetic comparison, as every change of light will enhance or modify the colour of reflected light, producing delicate tints on the surface from pale violets, blues, rose colours and orange, and the luminous grey it assumes in shadow is always restful and beautiful. I ask you to give attention to this suggestion.

We all know that white lead, mixed with oils or varnish, becomes in time discoloured, often in disagreeable patches, and finally degenerates into a nasty putty colour. I recommend the avoidance of oil or varnish and white lead on walls. The washable distempers to which I have alluded supply a want and deserve given attention and renewed experiment. I see around me many instances of the success of washable distempers.

Painting of wood deserves attention, and must be done with judgment.

We all know that in old days woodwork was invariably coloured; but between it and the pigment was laid a thin ground of "gesso," or plaster and glue, whereon tint and gilding were applied, rarely, however, mixed with oil or varnish.

No doubt this system is a preservative one against damp and the worm. So many instances are easily accessible to give that I need not enlarge on this subject, save to say that ornament on or the colouring of wood is a delicate problem. However, this much we all agree to, the colour it receives must be in harmony with the walls, neither too much darker or lighter, however different the tint may be.

If the tone of the colour is in excess either way, it will make a spot and injure breadth, so essential to all good colour decoration.

A blue room will stand a good deal of red, if the red and blue are nearly alike in tone value. Much red in a green room will prove inharmonious. In a white room pale blues, yellows, cool roses and greens will harmonise better than any red which approaches a terra-cotta tone. Before you attempt ornament—that is, pattern—the colour of the walls and woodwork must be determined and executed. Then a very little judicious pattern will suffice to satisfy the eye, please the sense and gratify the fancy; but ornament should come

Digitized by Google

last, not first, and appear to have grown out of the structural tones of colour.

It is undesirable to varnish woodwork; it had better receive a subdued polish. This is attained when the paint is quite dry by covering it with a thin coat of wax and petroleum; a delicate polish can be obtained by rubbing the surface gently with a soft old rag.

You will observe that I have only incidentally alluded to ornament.

Of course, in every instance one would prefer freehand painting to any artificial substitutes, but the best freehand painting is expensive. On woodwork I should certainly deprecate any but hand-painted patterns, but upon walls, as dado or frieze, stencils may be used. It is, however, useless to attempt to mask the monotony caused by any mechanism, though some of its more disagreeable adjuncts may be ameliorated. Stencil should remain obviously stencil. I have seen very agreeable results obtained when it has been frankly adopted, and I do not think that stencil as a cheap factor for tasteful and inexpensive pattern decoration has received the attention and amount of experiment it deserves. It has one obvious merit, flatness; it has another, "fancy" may be let loose and be pretty freely exercised within certain limits. Stencil has another possibility, it permits the use of a great variety of tints which may be so agreeably varied that the machine-like monotony of line design may be modified, even rendered useful and charming.

I can imagine a Japanese artist using the stencil as a colour agent with the distinction and delicacy he employs in the art of colour block printing.

I have said nothing about the use of gold as a pigment. Real gold is expensive, and no shams must come into our scheme.

A word or two about the framing of prints or photographs. Pictures do not come within the limits of expenditure in the case we are considering; better no pictures than bad ones. When we consider the cheapness of good photographs taken from the best existing art of all kinds of architecture, sculpture, painting and all the allied arts, and the reprints of engravings, the walls of a room may at very little cost be furnished in their reproductions of the masterpieces of the ancient and modern world. Photographs and prints tell best on a white wall if their margins are kept quite narrow. The touch of colour may come into their frames, which may be narrow reed pattern, coloured black, red, green, or blue; thus they may become pleasant notes of local colour which will redeem from monotony the quiet tints of the walls, furniture and woodwork.

A word on carpets and furniture. In carpets there are, I confess, in my opinion, few English which are interesting in design or satisfying in colour, but now the constant importation of oriental rugs renders good material, fine design possible to a limited purse. A carpet which covers the whole floor is surely undesirable. The dirty habit in the north of retaining the same shoes on our feet within our rooms that we wear out of doors is productive of the importation of dangerous germs and filthy produce where this should be sedulously kept out. To be really clean and healthy, carpets should be taken up once a week and the floor scrubbed.

There are some simple patterns of linoleum, a good wearing substance, quite inoffensive in design. These I advocate from experience, especially if they are waxed as wooden floors are, and then polished.

As to furniture, the simpler the better, always of unvarnished wood, and without distressing swirls and inconvenient edges so common in that much-to-be-deplored "L'Art Nouveau." A long settee made of pine, painted or stained an agreeable colour, furnished with a mattress and plenty of cushions, will form an admirable sofa, providing room also for several people to use as a seat. Where electric light is used, its fittings should be of metal and of simple design.

Here, then, I have given you a type of a dining or sitting room. If some of you more accustomed than I am to provide estimates will calculate the cost I suspect it will prove to be moderate and within the limits of expenditure suitable to a small income. It would be a room into which a person of good taste might be ushered and not wish himself away, and one which should encourage good spirits, good health, and would with careful management be kept clean and orderly.

The public is ever shifting and changing, because it does not really know what it wants. Like a tiresome child it wearies of toy after toy, even of the most extravagant and monstrous.

And in my opinion amelioration must begin from below; it must commence with the masses, not with the exceptions. It must begin where there is not too much money to waste, too little for extravagance and display, but enough to provide a wholesome, chaste decoration which shall have at the root of it refined selection and dignified repose without dulness.

The step in that direction must come from elimination of meaningless ornament, from an attention riveted on essentials, upon breadth of effect, simplicity of means, discrimination and good sense in matters of all design in whatever material.

Then people will begin to comprehend the word "fitness" which I have so often used to-day. And instead of vagaries we shall become used to good proportion, reserved forms, colours which are adapted to tone, and each special quality which gives its charm to every art in its right place, in its proper environment, being adapted to the grade in society that employs it.

COMPETITIONS.

MR. EDWARD CRATNEY, of Wallsend, has been awarded first place in a local competition for the design of new premises for the Newburn Urban District Council, Northumberland. Mr. Cratney will act as architect for the work. The second premium of 10*l.* has been awarded to Messrs. Marshall & Tweedy, Newcastle. Sixteen designs were received. The assessor was Mr. R. J. Leeson.

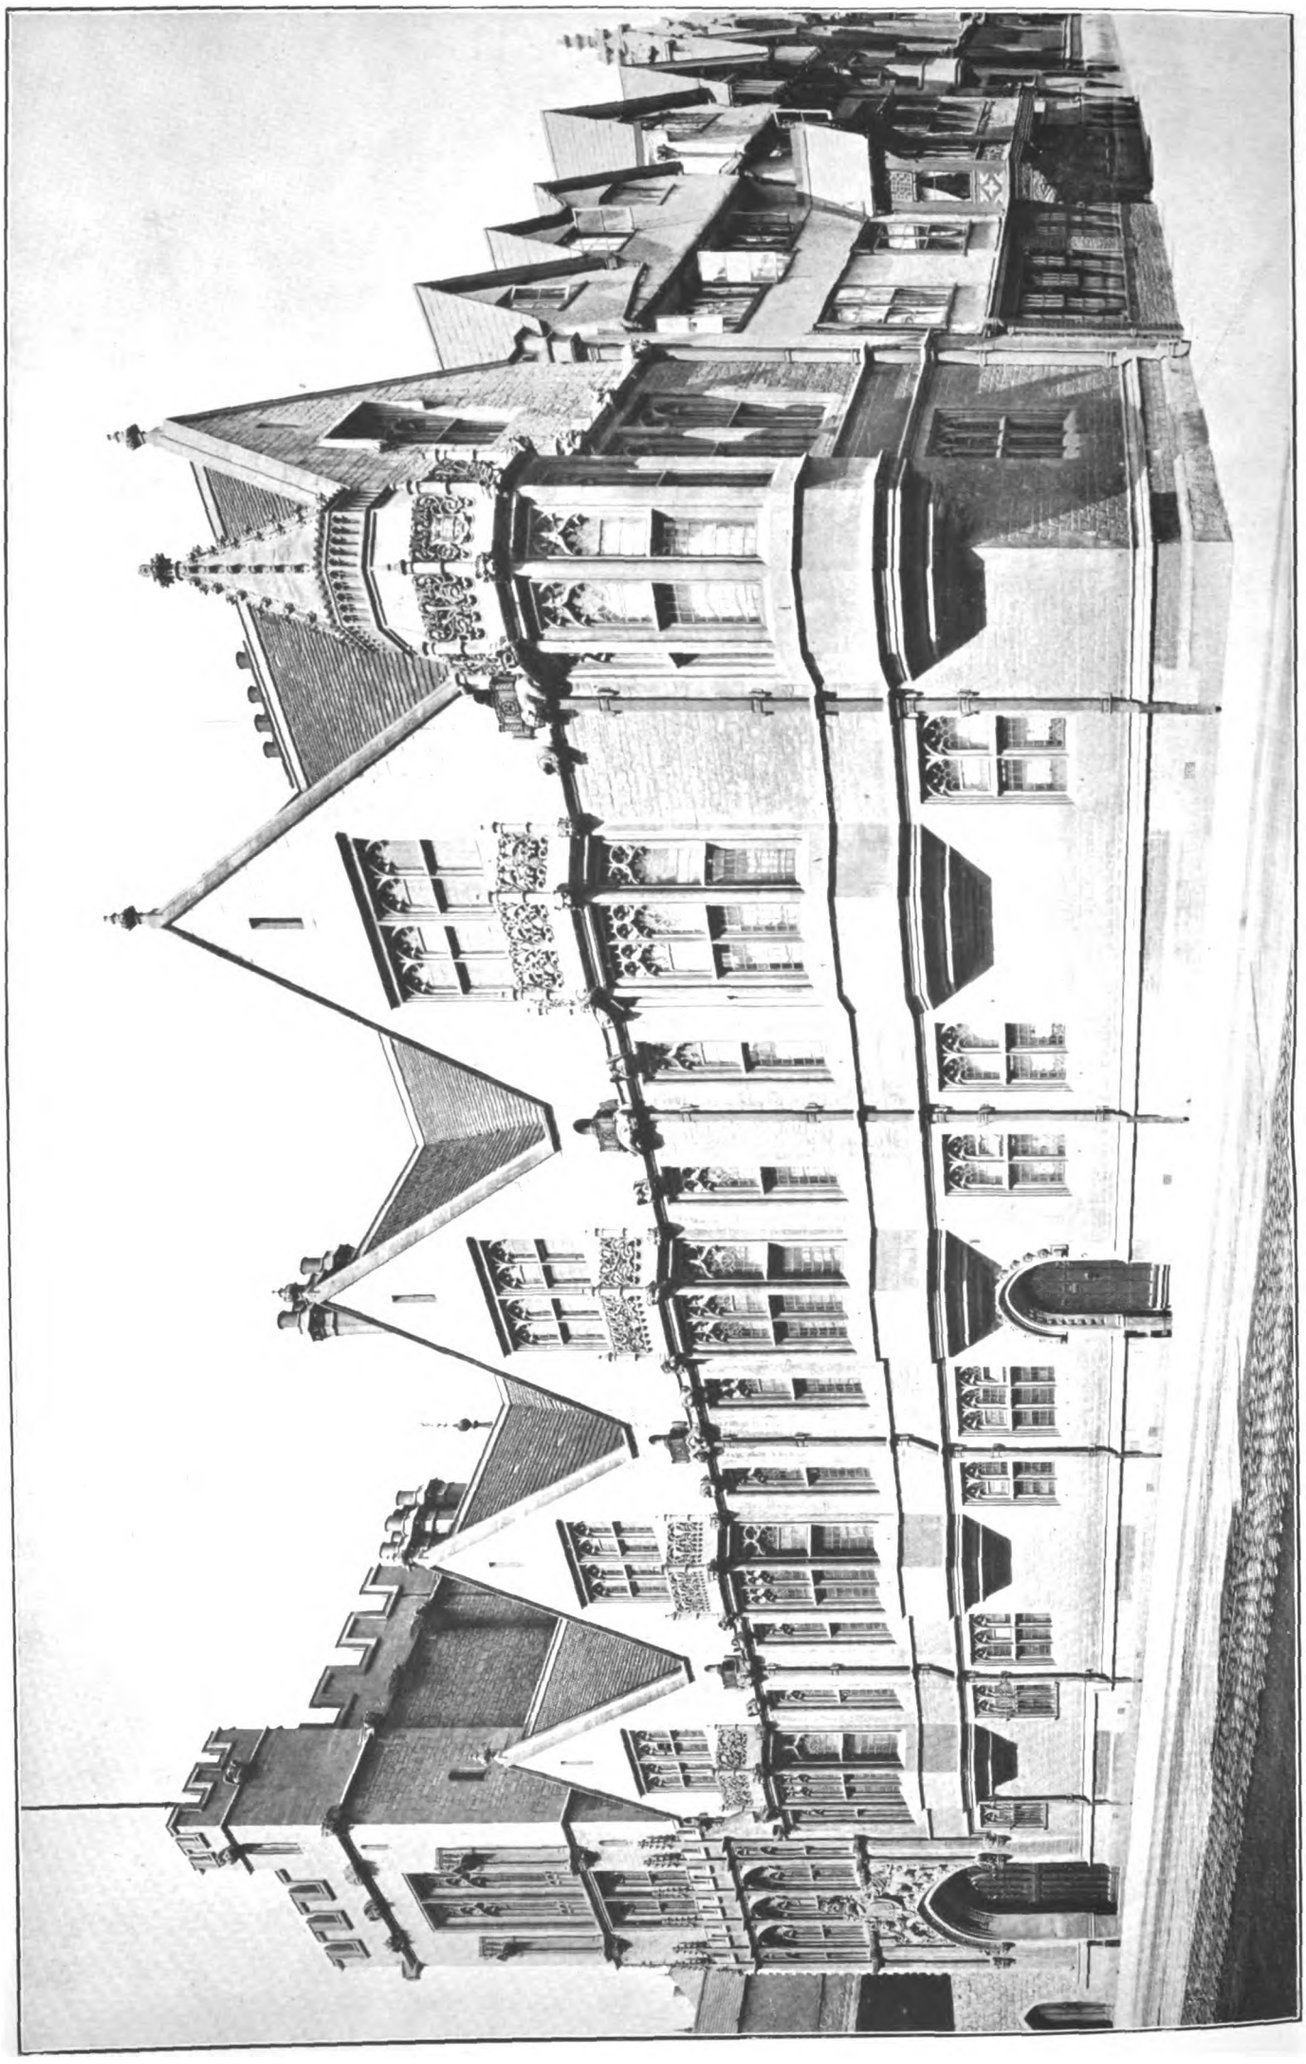
ILLUSTRATIONS.

SELECTED DESIGN FOR THE EXTENSION OF TOWN HALL, GRIMSBY.

WE illustrate this week the selected design by Messrs. EADE, JOHNS & BROWNE, of Ipswich, a description and criticism of which appeared in our review of the competition drawings last week.

OXFORD COLLEGE SERIES. BRASENOSE.—FROM HIGH STREET—CHAPEL QUAD.

WE now resume the publication of our series of views of the colleges of Oxford, and next week we shall give an historical account of Brasenose College, which we are now illustrating.



GARDEN FRONT OF HEATHCOTE, ILKLEY, FOR J. HEMINGWAY, ESQ.

THE drawing we reproduce was exhibited at the Royal Academy by Mr. EDWIN L. LUTYENS, the architect of this house. The design is evidently based upon the general feeling and to some extent the detail of an Italian villa, but the band of tile roofing over the entablature of the Order is, we take it, an experiment that does not seem to us quite successful, as it cuts the façade distinctly into two portions that do not look happy parts of the same design. The house is built of Blue Morsley stone from Guiseley, and the tiles were obtained from Holland by Messrs. VAN STRAATEN & Co., of London. We venture to think that in this design Mr. LUTYENS has made a mistake, but the deservedly high reputation he has attained as an architect of English homes has been obtained in part by daring originality and experiment, usually, in part by daring originality and experiment, usually who never made a mistake never made anything." The formal garden with its treatment of varying level is both clever and pleasing.

Mr. Charles F. McKim, senior partner of McKim, Mead & White, architects, died last week in his sixty-third year. At the age of eighteen he entered the office of Mr. Russell Sturgis of New York, and after a few months joined the Ecole des Beaux-Arts where he remained about three years. In 1872, being then twenty-five years old, he set up an independent practice. Five years later he was joined by Mr. W. R. Mead, and in 1879 by Mr. Stanford White. During 1901 and 1902 he acted as President of the American Institute of Architects, and in the following year Mr. McKim was awarded the Royal gold medal of the Royal Institute of British Architects. His own work and that of his firm marks an epoch in American architecture and has won the sincere admiration of his English confrères.

The Extensive Alterations to the chapel of St. John's College, Battersea, as designed by Mr. A. H. Ryan Tenison, F.R.I.B.A., were dedicated by His Grace the Primate on Tuesday last.

THE USE OF FERRO-CONCRETE IN MONUMENTAL ARCHITECTURE.*

(Concluded from last week.)

Construction of Pillars.

THE construction of pillars by means of pieces of artificial stone prepared beforehand can be omitted from our consideration, because this would only be a substitute for pillars of stone or brick without expressing any characteristic properties of concrete and its mode of construction. But these properties can be manifested in the construction of pillars in casting moulds *in situ*. The division into base, shaft and capital is no longer so important for the design of columns, as the whole pillar forms one block produced in one piece. We need only consider the æsthetic requirement of a division of too long lines, and this can be fulfilled by flat cinctures, which enable us to distinguish the parts of the pillar, although they are not necessary to strengthen the construction.

With regard to the transverse section of the pillar, we begin with the simple square or rectangular form, and we may obtain decoration by pieces inset into the casting-box, such pieces having the form of rectangular channels or quarter-pieces, the use of which leads naturally to the production of

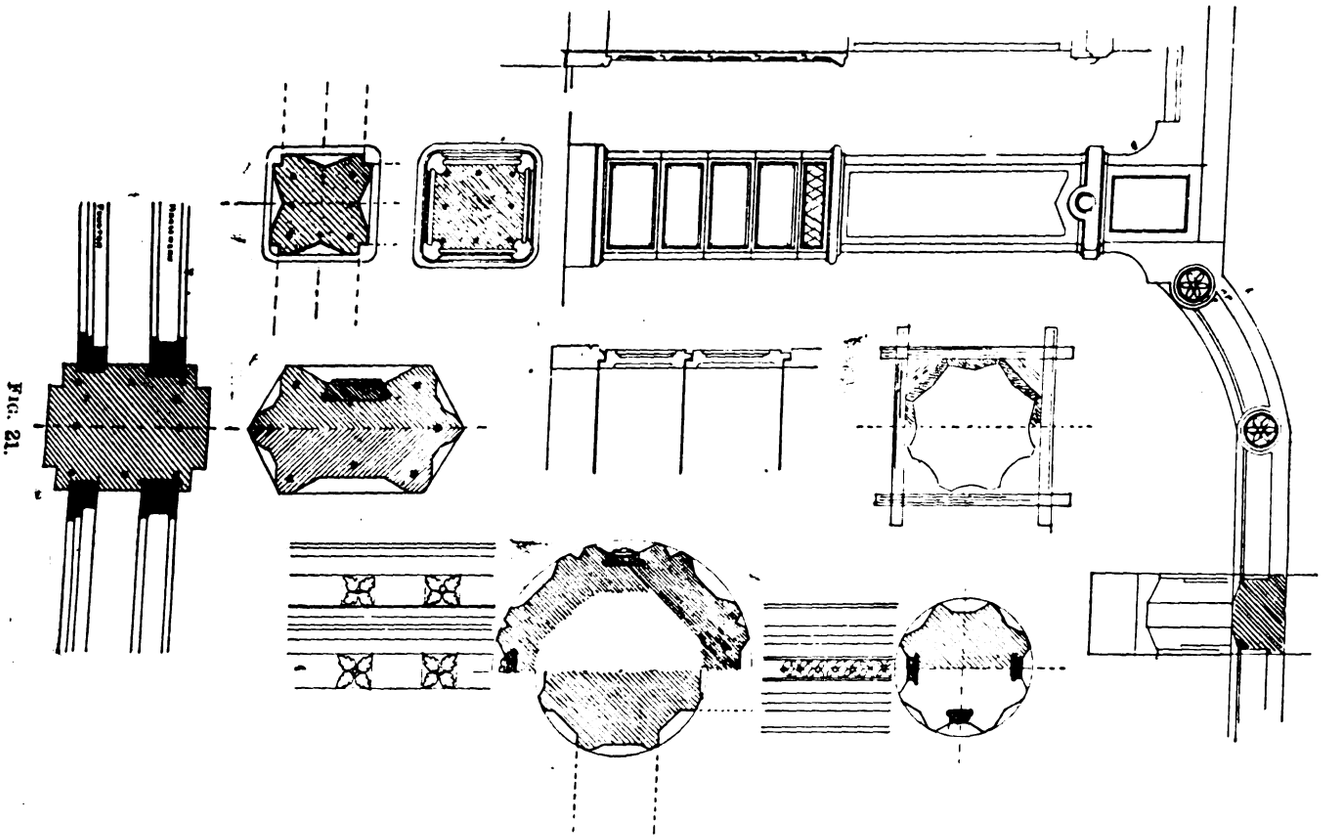

FIG. 21.

plain or star-like forms, which may be considered polygonal pillars or paraphrases of the round columnar pillar (fig. 21).

The connection between the pillar and the beam has also to be considered, and by means of console-like forms the expression of the pillar's function may be brought out (fig. 22).

Forms obtained by insets in the casting mould stand in close connection with the use of decorative pieces cast in concrete.

The pillars could also be partly formed with a kind of socle by putting together flat pieces of concrete which were made beforehand and which might be appropriately decorated, these pieces being joined by means of dovetailed connecting members and by grooves and feathers; the hollow space formed by the pieces, which is really the pillar, is then concreted.

Construction of Entablatures.

To meet the necessity of protecting the building in our climate from influences of weather by means of projecting roofs, and where this is not possible by means of cornices, concrete affords the possibility of forming appropriate shapes. The concrete corona made in the casting mould has to be given through appropriate enlargement an architectural bed mould, the lack of which is often felt very much; the projecting form in concrete need not be much divided, it may even be arranged in connection with the frieze. The lower parts can be partly formed as separate pieces, or might be included in the concrete casting (figs. 23*a* to 23*f* from the Law Courts at Brünn). The capacity of concrete for taking any shape in exactness and sharpness, giving the form in its fullest beauty, and not requiring any finishing, has been proved by a test made to produce decorative guards for hot-air tube and ventilation openings in the halls of the Law Courts at Brünn. These were produced in gelatine moulds. In order to carry out a suggestion made to me, an attempt will be made to utilise sand moulds for the casting of concrete much as they are used for casting metal.

The capacity of concrete for making easily and at a low cost highly ornamental forms would render it possible to take up again traceried treatment in architecture, following in an attractive way the decorative forms of the Gothic style. In connection with tall pillars or bay windows, church windows and also staircases, &c., a favourable opportunity would be given for its use.

Construction of the whole Building.

There is yet another question to be considered, and that is the real influence of ferro-concrete construction on building as a whole. In the suggestions put forward in the foregoing article concrete is not only treated as a material for ceilings, pillars and supports, but I have also endeavoured to show that concrete construction has a distinctive manner of expression.

In the study for a church design, which we have before us, and which is of basilican type with low aisles, besides the walls of the aisles the pillars are carried out in cast concrete, the ceilings of flat concrete in the aisles, and of coved concrete in the nave. The upper part of the high walls is stiffened by means of concrete buttresses, which would divide the load equally between the walls, reinforced by pilasters, and the nave pillars (fig. 24).

The execution of the concrete ceiling both in the model and in concrete, together with all tests and studies, has been carried out in the most careful manner by sculptor H. Koch, of Vienna.

The author does not deem his studies as yet concluded, but reserves to himself the pleasure of referring later on to studies already partly begun relating to the influence of ferro-concrete construction on the exterior of buildings, on the form of windows and doors, on oriels and towers, &c.

In reference to style, I should like to say that whilst the idea of inventing new styles has been dropped, the endeavour to express the "material style" as such remains; but at the same time in the expression of concrete construction certain details of a special kind have been brought into existence, and thus the nature of the material has been taken into account without incurring the danger of wandering into a labyrinth of styles.

The author has been especially prompted to express his views on the artistic ideas germane to concrete construction which now engage the thoughts of many people, in order that others who are following the same or similar lines may give their experience and the result of their studies to the experts. (This has already been done at the Eighth International Congress of Architects.)

But the question can only be developed further if engineer and architect are working together. In order to achieve this our Society, which has amongst its members both engineers and architects, is surely the most suitable forum.

therefore appear to be to open up a new road on the corre-
sponding side of the axial line which will be found to meet
at Blackfriars Bridge, giving a vista from this point of the
cathedral and assisting the traffic to take a direct route to
the city. The Fleet River has now given way to Farringdon
Street. Wren could not have anticipated a railway bridge
of iron and gilt ornament being erected at the foot of
Ludgate, which mars the view of St. Paul's by slicing the
building in two. Evelyn drew up his scheme simultaneously
with Wren, and both were presented to the King, and
although his Majesty accepted them, neither was carried
out exactly on the lines indicated. In later days Chambers,
Soane, Nash, Burton, Barry and others have respectively
shared the responsibilities of suggesting improvements for
London, while in provincial towns schemes were prepared,
such as that by Wood of Bath, and Liverpool, Manchester
and Edinburgh have had some attention in this respect.
To come to more recent times we have to be thankful for the
wave of feeling which has influenced the improvements to
St. James's Park and for Kingsway, and the proposals of
the Royal Commission on London Traffic. Mr. Paul Water-
house has dealt with this last-mentioned subject in a most
exhaustive paper read before the Royal Institute of British
Architects in May 1906, and which has prompted

of the General Post Office, would take the traffic into Finsbury and relieve much of the congestion of Wood Street and London Wall.

To start with a clear sheet, however, is a very different matter, and Mr. Lanchester has shown us in a recent paper he read before the R.I.B.A. in February last how the "Grand Manner" can be applied. His architectural Utopia reminds us of Hippodamos, who, Aristotle tells us, contrived "the art of laying out of towns," and was "the first author who wrote a treatise concerning the best form of government." Mr. Davenport Adams says he "designed the town of Peiræus," while another translator of Aristotle tells us he "separated the Pireus," but whichever may be correct, his name has been handed down to posterity in connection with this town by the district, apparently named after him, viz. Hippodamia, which is between the town on the peninsula and the long walls that lead to Athens. Piræus being the port of Athens, the work of Hippodamos must have been of considerable importance.

The importance from a commercial standpoint of a well-laid-out town plan is fully realised in America, where great efforts are now being made in this direction, especially at

Pittsburg and San Francisco, at which latter place no less than 25,000,000*l.* was spent last year alone for this purpose. It is very doubtful if much of the "Grand Manner" will be realised in London even in the near future, unless the Royal Traffic Commission's proposals are considerably modified and speedily adopted. Alterations in London are only effected after great pressure is brought to bear upon the authorities by the exigencies of the traffic problem, and even then the improvements are piecemeal and based apparently on no definite scheme. Is it not time, therefore, that a scheme were laid which should form the basis of future alterations upon a "rational plan," which ought to be drawn up by a representative committee with a knowledge of the respective interests both for art and commerce which govern the problem? Such a system would obviate the present indefiniteness, and the increased traffic facilities would be able to have consideration as to the most advisable way to provide for it.

Our squares and parks—the lungs, so called, of London—have a peculiar sameness which renders improvement difficult of suggestion. The former are for the most part far too small to be a pleasaunce, in the strict sense of the term, of any real use, and often too narrow. The best lay-outs are perhaps Lincoln's Inn Fields and Hanover Square, though in the latter instance the complete success is marred by the cramped surroundings of St. George's Church. Public opinion has severely criticised Mr. Speight's suggested improvement to the Horse Guards Parade and that portion of St. James's Park immediately contiguous to Sir Aston Webb's present alterations. It is a great pity this should be so, as we are far behind our Continental brethren in this respect, and suggestions of this nature are not to be lightly thrown aside. A good start was made to form and preserve open spaces based on an architectural theme by Sir Charles Barry when he laid out Trafalgar Square, and although he submitted a scheme for the raising of the National Gallery, inter alia, which, like Wren's plan of London, was rejected, he was placed upon the Royal Commission formed to investigate the best method of providing additional room for the museums, his suggestion being that they should be grouped at South Kensington, which project was adopted, but not until long after his decease.

With Mr. Brock's fine statue to Queen Victoria and the fountain in front of Buckingham Palace it is to be wished that an appetite for greater things will be given to the general public, even to the realisation of the hope of Soane, to wit, a new royal palace, which shall grace this rapidly developing royal park.

Our lack of fine sculptural groups is a slur upon our national prestige. When considering a grant for this purpose the execution is delayed indefinitely and just about the meanest site available placed at the disposal of the sculptor with which to "improve," a herculean task with no great thanks attached to it. For years it has been considered wanton waste to allow a greater area than, say, 100 square feet for the monument of an equestrian group, and little assistance is afforded in the treatment of its environment. If our sculptors were encouraged to produce good work by giving them greater scope we should not find the "horses backing off their pedestals," which is an American opinion of some of our much-honoured statues.

Although the alterations at the Marble Arch have temporarily solved a traffic problem, it cannot be said to be an architectural triumph. The arch itself has seen many vicissitudes, and its last state would appear to be worse than the first, but the gunmetal gates still hold their own against their new rivals.

The requisite width of main roads has been the subject of much controversy and very diverse opinions have been expressed. Whereas Wren stipulated three distinct widths, viz., 90 feet, 60 feet, and 30 feet, the Royal Traffic Commission recently fixed the main arteries at a size calculated to take a double row of tramway lines, 140 feet, to which Mr. Waterhouse objected as being too wide. It is a question, where trams occur, whether the road should not be wider, the rails being confined to the centre of three courses, as illustrated for a road of 220 feet, crossing a road of 140 feet, house-to-house. By this means the traffic would have an up and down route, separated from the trams by a narrow strip of pavement, with electric lamp standards, trees, entrances to underground conveniences, and cab-stands at intervals. are then necessary. Materials of this
more useful than the nondescript articles
are often now supplied.

All authorities agree that after the addition of a certain quantity of driers to linseed oil no improvement can be effected in the drying power. On the other hand there is no evidence to prove that excess of driers has the contrary effect. I believe that the presence of some metals, e.g., lead, tends to harden a varnish film, and when durability against external atmospheric action is not in question the presence of the metallic salt may be an advantage.

A German chemist has made use of this property in the preparation of a flatting varnish. He found that a varnish containing a requisite amount of lead drier was not hard enough to withstand rubbing down, but when agitated in the air with a mixture of litharge and zinc sulphate (white copperas) he obtained a product which was extremely satisfactory.

More than 15.2 per cent. of manganese should never be present in an oil, and for lead the limit of drying power is attained when 1.16 per cent. is present. It is not always necessary to employ the maximum quantities after consideration of the conditions; the less the better. Manganese and lead working in conjunction are more rapid driers than when used separately. If used in the ratio of 5 to 1 not more than 6 per cent. of the metal should ever be present, *i.e.*, 5 per cent. lead and 1 per cent. manganese. Other metals are less energetic than those mentioned, but I have found that .032 per cent. lead and .032 per cent. manganese will produce a small proportion of oxygen absorbed by the oil, and the presence of lead .77 per cent. will double the amount of oxygen absorbed and quality of the oil prepared from it. Linseed oil prepared from impure oil deposits certain impurities which are separated by the action of observers consists mainly of lead and manganese salts of the phates, while others consist of lead and manganese salts of the affect the drying power when allowed to remain in contact with duced by ageing are entirely removed by filtration.

Oils containing a lead drier have a maximum drying power when allowed to remain in contact with the oil for a tionship to the acid radicle of the drier. Thus the presence of the preparation of the oil, and the time of contact is greatly influenced by the nature of the acid radicle of the present. This salt may be precipitated by the addition tion has no connection with the drying power of the oil (as panied by a flocculent deposit. Oxygen plays a very important not essential. Oxygen does not exert its full influence when air is excluded the drying power is greatly reduced.

Manganese oils do not deposit any flocculent matter. ployed in the preparation of the oil, and the temperature to alter the drying properties of the oil. Thus oils prepared ent results have been obtained by different manufacturers. my opinion, the varying character of the results obtained accounts for these discrepancies. The temperature at drying oils, which interests us principally, is a very that I think it inadvisable to give any temperature at mental evidence. Only by the application of the observed facts can the riddles connected with the drying for some time linseed oil undergoes a change, A varnish prepared in this way will dry in one prepared, so far as is practicable, at a lower temperature.

The so-called "bunghole oils," that is, pared at ordinary temperatures, depend on according to some authorities the elasticity inferior to those of an oil prepared at 100° that lead manganese "bunghole oils" an increase power less if heated to 180°C. An increase ture considerably accelerates the drying process oil which in winter at normal room temperature in summer to seven days to dry, dries off in summer in days, while at 50°C. the process is complete in

Light is a very important factor when considered. Oils are bleached by the action of made an important observation in this direction, that the presence of oxygen was also necessary; closed bottles when exposed, underwent no change, common knowledge that paints and varnishes dry much rapidly when exposed to the light than when in the Chevreul was, I believe, one of the first observers to mine which kind of light accelerated the drying process. exposed under white glass dried first, while that exposed under red glass which cuts off all light of short wave length, dried least. Natural light varies so much in quality and quantity that it is too irregular a source with which to conduct exact experiments and in addition there is a liability of heat rays vitiating the results.

Genthe found a uniform source of light without heat in the mercury lamp. It is known that this source is rich in light of short wave length. When the lamp is enclosed in glass these rays are cut off, but if quartz glass is used this difficulty is overcome. This is the so-called Uviol lamp. Experiments proved that under the influence of this light raw oil and oil containing driers dried practically at the same rate. In the first part of the lecture I explained that the ultimate factor in the formation of the oil film was a peroxide produced in the oil itself. If this is correct and the Uviol lamp is able to make raw linseed oil dry at the same rate as oil containing drier, then the rays from the lamp must have the property of directly producing in linseed oil that efficient peroxide which in the presence of oxygen is capable of producing the solid oxidation product.

This discovery appears to me of such far-reaching importance that it may be of interest to give a short account of the patent which has been taken out for producing drying oils by this process on a commercial scale.

This method has the object of producing from linseed oil, &c., drying oils which have not the defects of oils

* Abstract of a paper read before the Paint and Varnish Society by M. B. Blackler.

Digitized by Google

obtained by other methods. The autocatalytic agent formed during the natural drying process is produced by artificial means. Under the influence of light of short wave length produced by Uviol lamps, air is pumped through linseed oil and in this way typical peroxides are produced. These are the catalytic agents which accelerate the drying process, whereas all other driers only accelerate the production of these autocatalytic agents.

The drying oils obtained by this method have particularly valuable properties. When applied the oil dries rapidly and instead of forming a skin a complete solidification takes place, giving a brilliant non-sticky coating which resembles varnish in appearance. This glowing description may be somewhat too laudatory, but nevertheless I think that a distinct advance has been made by the discovery of this process.

The operation is carried out as follows:—

A vat illuminated with twenty Uviol lamps, is charged with 1,000 kilos of oil warmed to 80°C. Oxygen in a finely divided condition is then passed through the oil—the energy of the reaction is sufficient to keep up the temperature without the application of external heat.

It is so well known that all painting should be carried out in a dry atmosphere that the effect of moisture may be considered as outside the pale of consideration. Unfortunately ideal conditions cannot always be chosen, so it may be well to inquire whether all driers are affected by moisture in a similar degree.

Tanked linseed oil, raw linseed oil and hemp oil, all dry much more slowly in a moist atmosphere than when the air is dry.

Oils containing a mixed manganese lead drier certainly dry more rapidly in a dry atmosphere, but the retarding action of moisture is not very pronounced.

Manganese alone offers the most curious study. When comparatively large quantities of this metal are present in an oil, i.e., .1 to .2 per cent. moisture may be said to practically prevent oxidation. This point is well illustrated by the following result due to Lippert:—

Manganese Boiled Oil ·2 per Cent. Manganese (Lippert).

Date.	Time.	Weather Conditions.	Temp.	Weight of Film and Oxygen Absorption. Dry Air.	Moist Air.
Put in Nov. 22.	5 p.m.	Bright	9°	367 m.g.	449 m.g.
Put in Nov. 23.	4 p.m.	Bright	14°	+58=15·8%	+5 (dry) 1·1% (wet)

On the other hand when the quantity of manganese is gradually decreased the drying power gradually increases in the moist atmosphere and decreases in the dry atmosphere. With .02 per cent. of manganese Lippert obtained results as follows:—

Manganese Boiled Oil ·02 per Cent. Manganese (Lippert).

Date.	Time.	Weather Conditions.	Temp.	Weight of Film and Oxygen Absorption. Dry Air.	Moist Air.
Put in Nov. 30.	12	Bright	15°	388	310
After 5 hours .	5	Bright	15°	+3=0·8%	+8=2·6%
After 24 hours .	12	Bright	15°	+29=7·5%	+40=13%
After 47 hours	11	Bright	15°	+51=13·2% (sticky)	+50=16·1% (dry)

The introduction of a very small quantity of manganese into raw oil makes it at once capable of drying more rapidly in a damp atmosphere than in dry air.

Complicated theories and scientific data are useless for commercial purposes unless results for the practical man can be derived from them. I will now put forward a suggestion which I think can be deduced from the facts which I have already placed before you. It is probable that many gentlemen present will neither agree with these opinions nor with those already expressed, but this will invite discussion, and after all, interchange of ideas and opinions is the main object of the society. The drying of linseed oil can only be accelerated by the addition of the metals manganese and lead, or the two combined. So-called colourless liquid driers composed chiefly of calcium resinate with small amounts of lead salts are in the majority of cases useless as driers, particularly when they are added to paint for outside work. There is a certain quantity of drier which can be used with advantage. When using pure lead drier the maximum quantity of metal is 1.6 per cent. of the oil present, whereas when manganese is used alone, not more than .15 per cent. of metal should be employed.

For general work a mixed drier is most satisfactory—e.g., .23 per cent. of lead and .046 per cent. manganese oxide gives good results.

In summer time, when the general weather conditions are good, very much less drier can be effectively used.

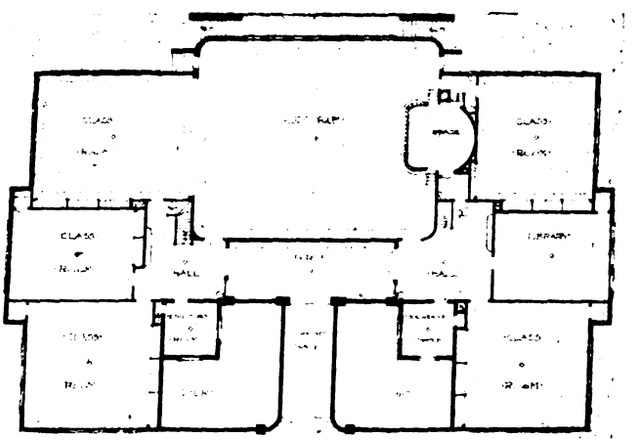
For outside work in dry weather a pure manganese drier (notresinate) should find application, whereas in damp weather this should be replaced by a manganese lead mixture.

Although much has been written on the subject of driers and drying oils the literature as yet contains no reliable information concerning the correlation between the durability of the oil film and the amount and kind of drier employed. I know that some of our members are interested in the microscopy of the subject. Here is a field of research which offers work for all. Unfortunately a few experiments are useless when dealing with a subject of this nature. The oil, the drier and the conditions of exposure must be definitely characterised if the results are to be at all useful.

In common justice to those concerned it is necessary to state that when preparing this paper I consulted practically all the original papers published in the English and German literature during the last fifteen years, as well as the more important literature on the subject. My thanks are, therefore, due to Andés, Fahrion, Lippert, Mulder, Livache, Weger and many other gentlemen who have contributed to the literature of drying oils and driers.

CONCRETE SCHOOL BUILDING FOR DUARTE LOS ANGELES, CALIFORNIA.

IT is a satisfactory sign of the progress of the times that the general public, and more especially the official public, is waking up to the appreciation of first-class work, permanent in character and attractive in design, and demanding from the engineer and architect structures that will in all respects fill the call for more substantial and permanent types of construction.



There is no class of structure that calls for attention on artistic lines and careful consideration of accommodation and sanitation more than that of school buildings.

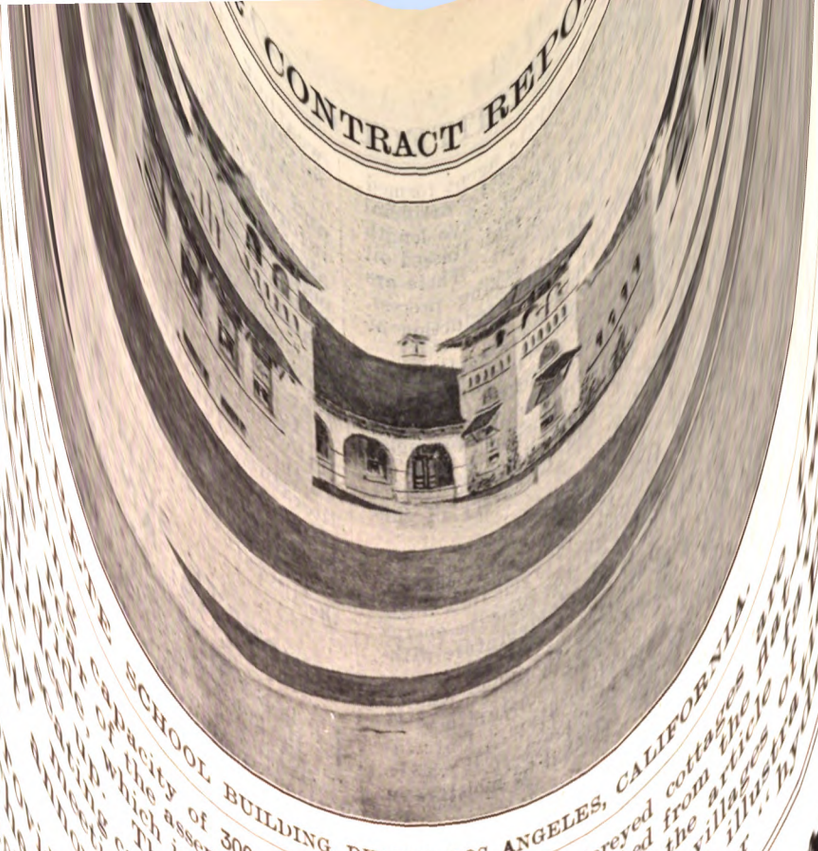
Concrete construction undoubtedly furnishes the substantial requisite, and lends itself very readily to the artistic conception of the architect. The erection of a school building at Duarte, California, is now being completed, and has some interesting features in arrangement.

The building is a one-storey and basement school-building of the Spanish mission type, and has a picturesque effect, with its open court in front, wide entrances, towers, and projecting eaves.

The building is of reinforced concrete construction, the mixture being of one part Portland cement to six parts of good clean Arroyo gravel, machine mixed.

The vertical reinforcement consists of ½-inch square steel, 12 inches on centres in walls, and four bars in each mullion.

PLAN OF SCHOOL BUILDING, DUARTE, LOS ANGEL ES.



The horizontal reinforcement consists of ½-inch square twisted steel, 12 inches on centres, with ends lapped 20 inches, and with an additional reinforcement of ¾-inch twisted bars under and over all openings and around in top of the walls. The exterior is plastered with one part of cement to two parts of sharp sand, put on with an even brush dash.

The roof is covered with tinned and galvanised iron Spanish tile. The galvanising was done after bending the tile into shape.

The exterior walls are painted with two coats of cold-water paint in a rich cream colour. The window-frames, rafter-ends and all trimmings are painted in clear white. The roof is painted in a warm burnt-clay tile colour.

The building contains (see plan) on the main floor four large and one small class rooms, large library, office, and teachers' rest-room, and also a large assembly hall with the

Berkshire County Council Offices.

SIR,—We note in your criticism of the above Mr. Mould's name is alone mentioned in connection with the plans prepared by him in conjunction with Charles D. James. We might also call your attention to the fact that the cubing price allowed by us for all the main fronts was 10*d.* per cubic foot, and not 4*d.* Fourpence was allowed for the new large hall, suggesting ferro-concrete for the constructive material, the plan being so arranged that its side elevation is not seen in conjunction with the elevations facing the town hall square. We are bound to admit that the price allowed by the conditions of the competition was small, but we consider that we could have carried out the building for the price allowed by the use of the materials we suggested, especially as we expected to make a big score by the fact that we have saved the present building practically intact, which apparently the successful scheme has not attempted to do.—Yours faithfully,

STUART M. MOULD,
CHAS. D. JAMES, } Joint Architects.

ment upon the fact that the authors of the above
first have not adhered to the conditions governing
the private road. You do not, however, appear to
a very serious matter.

We therefore beg to inform you that Messrs. Sutton
the right to build on the front and back portions of this
and moreover from information given us there is a probability
of their ultimately doing so.

In addition to question 38 referred to by you, question
36 bears upon this matter. We quote below the question to
which the answer was "No."

"36. Is the County Council to have 'a right of way'
over the land between building lines?"—Yours faithfully,

NORTH & ROBIN.

203 Strand, W.C.: September 16, 1909.

[We pointed out in our review that although the Council have no "right" to use of the private road, they may possibly be permitted the user by courtesy.—ED.]

Grimsby Town Hall Competition.

SIR,—We note in your review of the above Mr. Mould's name is alone mentioned in connection with the plans prepared by him in conjunction with Charles D. James. We might also call your attention to the fact that the cubing price allowed by us for all the main fronts was 10*d.* per cubic foot, and not 4*d.* Fourpence was allowed for the new large hall, suggesting ferro-concrete for the constructive material, the plan being so arranged that its side elevation is not seen in conjunction with the elevations facing the town hall square. We are bound to admit that the price allowed by the conditions of the competition was small, but we consider that we could have carried out the building for the price allowed by the use of the materials we suggested, especially as we expected to make a big score by the fact that we have saved the present building practically intact, which apparently the successful scheme has not attempted to do.—Yours faithfully,

CHAS. D. JAMES, } Joint Architects.

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *American Architect* treats us to some illustrations of garden architecture in the shape of Mr. G. W. Wattles's garden at Hollywood, California, and some picturesque bits entitled "Glimpses of Rural England," which include some of Mr. Lutyens's work and Mr. Thackeray Turner's home.

Deutsche Bauzeitung illustrates a new paper-mill at Waldhof, near Mannheim; the Victoria and Albert Museum, Imperial Institute and Natural History Museum, and gives an account of our group of national museums at South Kensington.

La Construction Moderne celebrates the respite from destruction of an eighteenth century house in the Rue de l'Université, Paris, by giving an illustration of some of its carved and sculptured detail, which is of quite excellent quality.

Dekorative Kunst describes and illustrates three country houses by Hermann Muthesius, one in Zehlendorf-West, one in Lübeck, and one in Grunewald, all of which, though thoroughly modern German, show that Herr Muthesius has not studied English domestic architecture for nothing. There are also illustrated some very charming examples of modern jewellery, the work of Paul Haustein.

Der Profanbau gives an illustrated account of the municipal housing scheme of the city of Ulm, which has covered an estate quite picturesquely with houses for its workmen and other employés of what is called the lower middle-class.

FORTHCOMING EVENTS.

Monday, October 4.

Royal Academy: Course of six Lectures on "Chemistry" by Professor A. H. Church, D.Sc., M.A., F.R.S., opens. Subject: "Paper, Canvas, Panel, and other grounds."

Society of Engineers: Meeting in Room 18 Caxton Hall, Westminster. Paper on "The Status of the Engineering Profession," by Mr. G. Allan Thomas.

Tuesday, October 5.

Institution of Heating and Ventilating Engineers: Meeting at the Institution of Mechanical Engineers, Storey's Gate, S.W. Papers on "Heating of a Hospital," by Mr. F. B. Craig, and "A Few Thoughts on Fans," by Mr. Oswald Stott.

University Extension Guild: A course of twenty-four weekly lectures on "Ancient Architecture" opens at the British Museum, by Mr. Banister Fletcher, F.R.I.B.A.

Wednesday, October 6.

Royal Society of Antiquaries of Ireland: Excursion to St. Doulough's, Malahide and Swords, County Dublin.

Thursday, October 7.

Civil and Mechanical Engineers' Society: Meeting at Caxton Hall, Westminster. Presidential address by Mr. W. Noble Twelvetrees.

Friday, October 8.

Architectural Association: Annual General Meeting. President's address and distribution of prizes.

TOWN PLANNING IN PRACTICE.

IT is easy enough to sit down with a map of some city or town before one and to imagine new streets that will possibly have some advantage over the existing arrangement, but this is a very different thing to planning a town so that all the considerations that should be taken into account are properly and most beneficially brought under review and their relative importance given due weight. Some idea of the multitude of these considerations may be obtained from a perusal of Mr. RAYMOND UNWIN'S book on "Town Planning in Practice." *

To begin with, the ambitious novice in town planning should study what has been done in the past. He will learn that town planning on a definite system was practised so long ago as 3,000 B.C. in the laying out of the ancient town of Kahun, built to accommodate the workmen engaged in the building of the pryamid of Illahun. This is the earliest at present known example of a town laid out on a regular plan, and follows the rectangular arrangement of blocks characteristic afterwards of Ionian, of Greek, of Roman and of American town-planning.

Such an arrangement one can readily understand as being especially suitable to the housing of a large number of workmen strictly organised under a quasi-military discipline and divided into companies and sections. Thus it was adopted in the Roman prætorian camp, and following this precedent in the Roman town. The system of land tenure prevailing in the city of Rome itself, where the ground was divided into insulæ, each of single ownership, was admirably suited by the rectangular block arrangement of streets and lanes. For financial reasons such a system of cutting up the site of a city is admirable, and where, as in New York, the land for occupation is limited by natural boundaries it is almost imperative. There are no acute angles nor curved lines to waste an inch of ground in sites of awkward shape.

On the other hand, the rectangular block arrangement does not make for convenient access from point to point, but will most usually demand the travelling round two sides of a triangle instead of one. Little wonder then that in America they are coming to realise the advantage of diagonal thoroughfares across the rectangular blocks and directly connecting the vital points of the city's life, as in Philadelphia and Washington.

Kahun may be taken as the prototype of the formal school of town planning, and as the ancestor not only of the strictly rectangular block disposition, but of the grand manner of the Renaissance period. In this the monotony and the restricted perspective of the American type are relieved by the provision of open squares, of avenues, of grand and wide approaches to some important and stately building.

Next we have the radial type of plan, of which Karlsruhe is so striking an example, a type suited to a town which has but one centre on which all interest is focussed, a town in which one distinctive feature dominates the whole. One cannot but admire as a clever combination of these types Sir CHRISTOPHER WREN'S plan for the rebuilding of London. For scenic effect, for convenience of traffic, for emphasis of the vital centres, it would be difficult to find a plan more suitable for the London of the seventeenth century than was WREN'S, and even for our own time how far preferable it would be to our overgrown lines of the mediæval town.

The mediæval town as a general rule is the precise antithesis of the formal or Kahun type. It appears to have grown up haphazard almost, or at least regulated only by natural considerations of contour and of environment, more often than not enforced by the particular disposition of fortification which these required in each instance. But as Mr. UNWIN points out, the modern German school of town-planners is disposed to argue that what appears to us at first sight the haphazard result of accidental growth has been in reality deliberately designed under the influence of artistic impulse felt, if not clearly recognised.

Therefore, say the Germans, we should endeavour consciously to reproduce the devious lines and varying width of streets, the closed vistas produced by the breaking off from directness of thoroughfare that are so characteristic of mediæval towns. A town plan by a modern German architect, such as that of Kufstein by Herr OTTO LASNE, looks very rambling and confused compared with the regular gridiron of an American city; but in studying a town plan one must above all things picture it at the street level, and not from a birdseye view as one sees it on a map or drawing.

Thus we have two distinct schools of town planners as of garden designers, the formalists and the informalists, and Mr. UNWIN devotes a chapter to a critical consideration of formal and informal beauty, the varied claims of which he very fairly discusses without dogmatism and with due recognition of the principle that each individual problem has its most appropriate solution.

A highly important chapter to the student of town planning is that "Of the City Survey." In this the author gives an indication of the many data that are required before the plan of a town can be commenced—the lines of traffic and their relative importance, the prevalent winds and their intensity, the rainfall, the nature and requirements of present and future industries, the social aspects of the life of the future inhabitants, the natural beauties of the locality—all these and many other points must be investigated and taken into account.

* *Town Planning in Practice: An Introduction to the Art of Designing Cities and Suburbs.* By Raymond Unwin. (London: T. Fisher Unwin. 21*s.* net.)

Digitized by Google

Should the town-designer's predilection be for the mediæval type of plan rather than the formal, he should not forget that in very many instances one of the vital elements in determining its lay-out was the disposition of its fortifications and the influence thereof on the character of its boundaries and approaches. Nowadays we have no fortifications to limit or to guide us, and it would be pure affectation, not to say, crass disregard of the nature of our modern problems, to follow too closely on the mediæval pattern made under widely differing conditions. Take Rothenburg-on-the-Tauber, for example, that marvellously picturesque Bavarian town that, if not altered since we were there some years ago, still preserves its walls as they were left at the close of the Thirty Years' War. Its picturesqueness, as shown by numerous photographs in Mr. Unwin's book, we must all admire, but it does not necessarily follow that we should copy in every instance, or necessarily in any instance, its disposition of streets and thoroughfares.

"Centres and Enclosed Places" and "The Arrangement of Main Roads" are two vitally important sections of the question of a town plan to which Mr. Unwin has devoted very careful attention, and which he explains with much lucidity. The difference between the Parisian and the modern German quasi-mediæval methods of planning are in no branch of the subject more pronounced than in these matters, and the relative advantages of the two schools must be thoroughly understood and their application to particular instances carefully thought out.

"Site Planning and Residential Roads" require in addition to well-planned vistas, whether closed, as Mr. Unwin, we fancy, seems to prefer, or open, a very careful attention to aspect, one of the most important factors in the production of healthy and comfortable residences.

The general considerations of the massing of towns must be followed in their planning in practice by those of "Plots and the Placing of Buildings" and of "Co-operation in Site Planning," and on these points apt illustration of the advantages to be gained is afforded by the examples given us by Letchworth and Hampstead Garden Suburb, in which such excellent results have been achieved by Mr. Unwin and other architects associated in their production.

The final chapter of the book before us treats of "Building By-laws" and their generally unsatisfactory influence from the point of view of architectural design and beauty, and the author points out how with less arbitrary rules and regulations not only would the æsthetic requirements of town planning be better compassed, but the hygienic aspect would be more largely promoted.

We cannot altogether agree with the preface, in which our author modestly urges that he has only been able "to deal in an introductory and imperfect manner with the different points raised." Introductory the work may be, for in England the subject of town planning as a form of art is but in its infancy; but we consider that Mr. Unwin's work is an admirable and perfect introduction to his theme, containing most useful lessons and suggestions and adequately dealing with the many and complex problems that the new art of town planning involves.

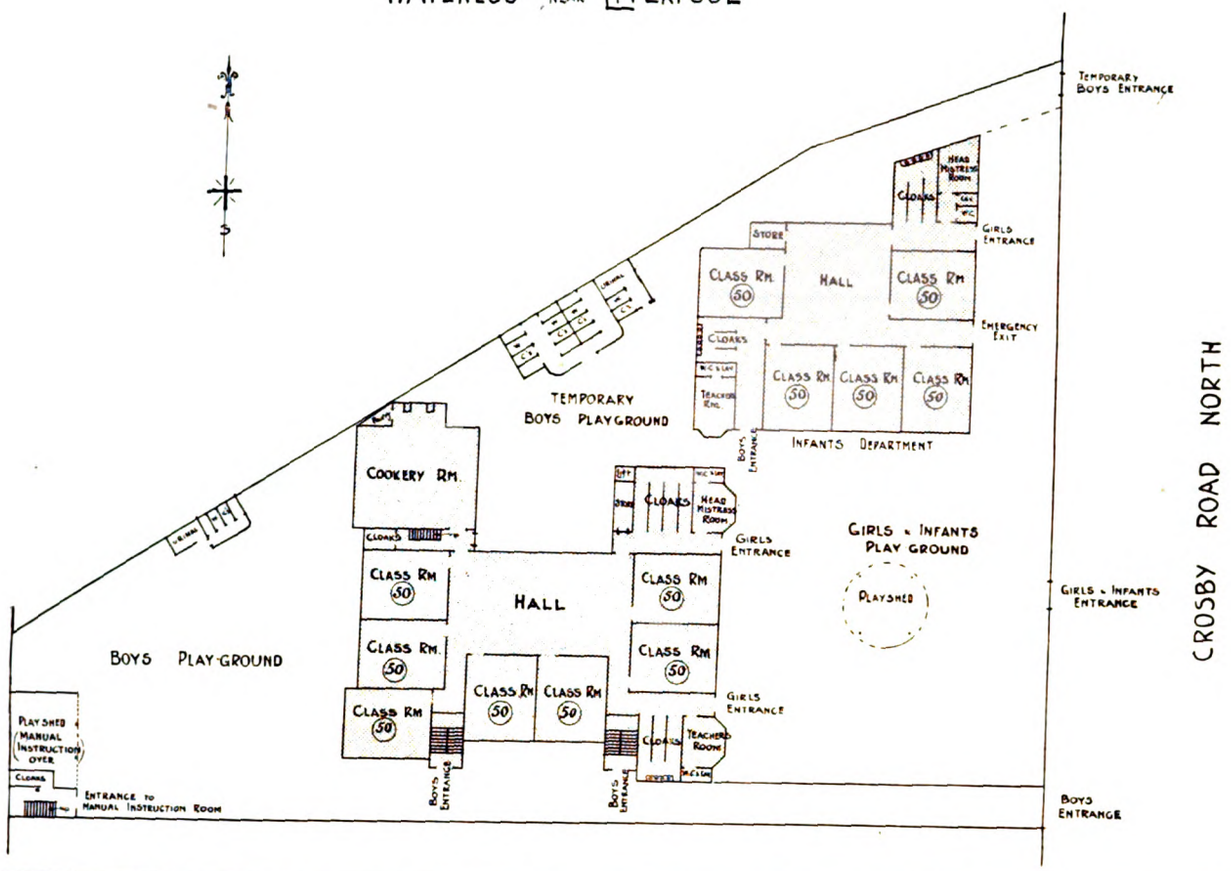
NOTES AND COMMENTS.

We are naturally pleased, as no doubt all of our readers will be, that the Chancellor of the Exchequer on Tuesday last conceded the exemption from the tax on minerals of clay, sand, gravel, chalk, and limestone, recognising the very serious influence that such a tax would have on the British industries of brick and tile-making and of Portland cement manufacture. We venture to take some credit to ourselves and our contemporaries in the technical Press for the concession as the result, at least in part, of the arguments that have appeared in our columns and have been brought to the notice of those members of the House of Commons whose constituencies are especially interested in the industries affected.

A museum is essentially more than a mere storehouse of curios or even valuable objects. It is an educational institution, and everything therefore that makes a museum more useful to those who wish to learn enhances the value of the institution and of the benefit to the public that justifies its existence. The British Museum has for some time past been used for object-lessons by visiting bodies of students from various institutions and organisations, and lectures or expositions have been given by members of the staff or by leaders of the visiting students. Under the auspices of the University Extension Guild, and by permission of the trustees, a new departure is next week to be initiated in the shape of a series of lectures, illustrated by lantern slides.

The subject of these lectures is to be "Ancient Architecture," and they will deal with Egyptian, Assyrian, Persian, Greek, Roman, Early Christian, and Byzantine architecture, and will be delivered by Mr. Banister F. Fletcher, F.R.I.B.A., commencing on Tuesday next at 4.30 p.m. The course will comprise twenty-four lectures, and since the object of University Extension is rather general culture than technical training, they will be arranged for the benefit of art students and the general public rather than of architects solely. The reason for such lectures being given at the British Museum rather than at some other centre is, of course, that there, surrounding the students, are the concrete illustrations, far superior to lantern slides, of the subject of the instruction given. We understand that full particulars and prospectus can be obtained from Miss Gaudet, Hon. Secretary to the Course, at 120 Cheyne Walk, Chelsea.

The programme for the sessional meetings of the Royal Institute of British Architects for 1909-10 commences with the President's opening address on November 1, and includes papers on "The Planning and Laying Out of Public Places," by H. Inigo Triggs; "Architectural Education in America," by A. D. F. Hamlin, A.M. (Columbia University); "Carr of York," by S. D. Kitson, M.A.; "George Frederick Bodley," by Edward Warren, F.S.A.; "The Business Side of Architecture," by A. A. Hudson, Barrister-at-Law; "Architecture of the Balkan States," by George Hubbard, F.S.A.



Great satisfaction has been expressed at the discovery by Mr. Sydney Perks, the City Surveyor, of the two fifteenth-century windows at the London Guildhall, which we described and illustrated last week, and further investigations are to be made in the hope of additional finds. Mr. Perks seems to have the true archæological instinct, and if there is anything more to be brought to light we may trust him to make a fruitful quest.

The Bishop of Carlisle hit the right nail on the head when he stated his view at the Diocesan Conference during the discussion on the question of ecclesiastical dilapidations, that when a glebe house was once placed in good tenantable repair a few pounds spent every year would keep it in order. The same policy should be applied by the clergy to the cathedrals and churches under their charge, then restoration would be unnecessary, and sustentation would always keep the fabric in good order at far less expense. Dilapidation and decay have a way of increasing at compound interest, not to say geometrical ratio.

There is a great deal to be said in favour of the scheme laid before the Conference for allotting to the Ecclesiastical Commissioners, and the Queen Anne's Bounty Office the duty of undertaking the entire charge of repairs to glebe property, subject to a compulsory fixed charge on the incumbents of about 2½ per cent. on the net income of their livings. The official body would then become a kind of insurance office and relieve the clergy of the disagreeable necessity of finding lump sums of considerable amount at somewhat uncertain and therefore inconvenient seasons. Whether the Ecclesiastical Commissioners, with their extensive experience of house property, would deem the 2½ per cent. a sufficient premium for the insurance is quite another matter.

PROPOSED ELEMENTARY SCHOOLS
WATERLOO NEAR LIVERPOOL

COMPETITION DESIGNS FOR SCHOOLS AT WATERLOO AND SEAFORTH, LIVERPOOL.

IN May 1908 the Urban District Council of Waterloo-with-Seaforth invited competitive designs for schools at Waterloo and Seaforth, and have recently made known the result.

The successful competitors for both schools are Messrs. Appleyard & Quiggin, A.R.I.B.A., of Lord Street, Liverpool. Seventeen sets of designs were submitted for the Crosby Road North school, Waterloo, and sixteen sets for the Rawson Road school, Crosby.

Crosby Road North School, Waterloo.

This school was intended to accommodate 1,000 scholars in three departments—viz., 350 boys, 350 girls, and 300 infants, in separate departments. It also had to be designed so as to be erected in sections, the first portion to be a department for 350 mixed and infants, with a cookery room.

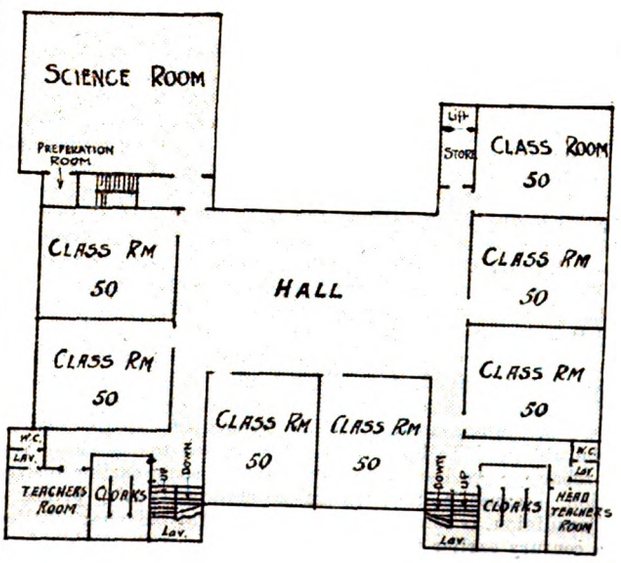
It is proposed to build the ground floor of the mixed department in the first instance with a flat roof, and running the parapet walls to sill height of the first floor.

We notice that the infants' department only provides for 250 scholars.

The emergency exit in the infants' department does not appear necessary, as the entrances are so placed that easy exit can be made in case of emergency. No doubt the authors provided this exit in accordance with the conditions.

The general arrangement of the scheme appears satisfactory, and though the boys' staircases have no communication with the ground floor in the mixed department, yet access from the ground and the first floor can be obtained by means of the staircase in the cookery and science section.

Rawson Road School.



The school when completed is to contain 400 in the mixed department and 200 infants, together with a special subjects' department with mistress house attached.

In the first instance it is proposed to erect a department for 350 infants and children of both sexes and the special subjects' department.

The conditions of the competition required emergency exits to be provided. The emergency exit in the infants' department is not required, and the space could well have been adapted for a store.

The position of the cloak rooms does not appear to be very satisfactory, as the scholars must of necessity have to retrace their steps either entering or leaving the school. Otherwise the scheme is satisfactory.

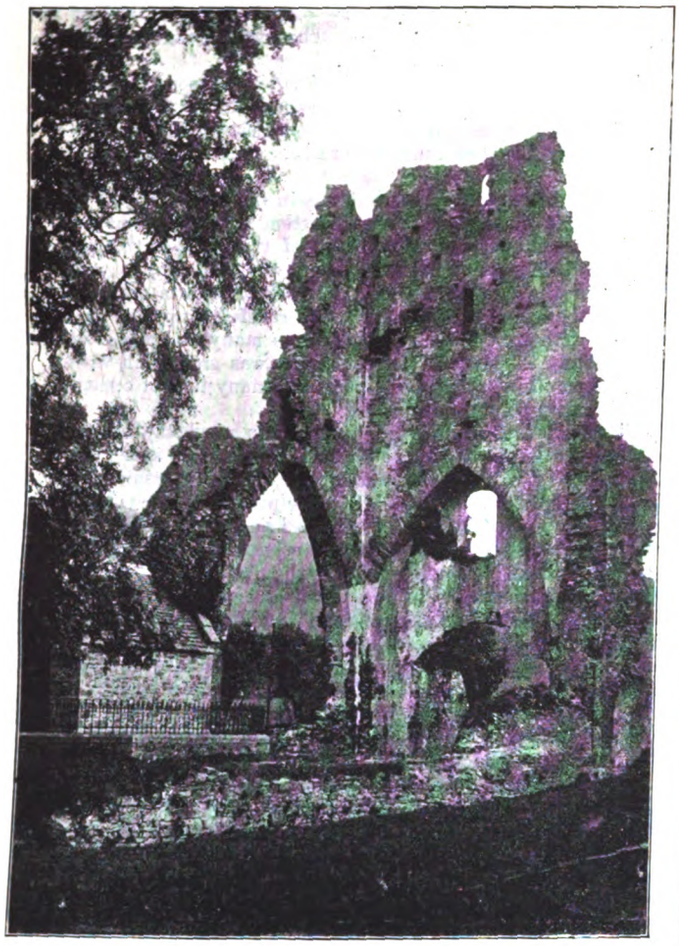
Proposed Elementary Schools
Seaforth near Liverpool

First Floor Plan

TALLEY ABBEY, CARMARTHENSHIRE.

By Professor E. Tyrrell Green.

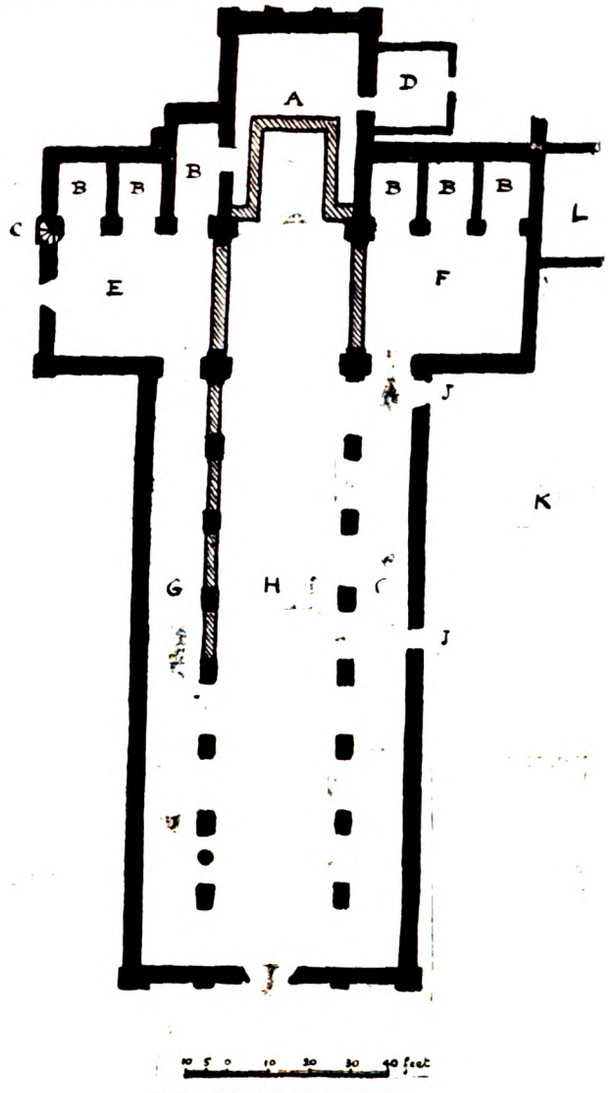
THE foundation of Talley Abbey is generally attributed to Rhys ap Gruffydd, Prince of South Wales, just before the close of the twelfth century. This was the same prince who founded the great Cistercian monastery of Strata Florida in Cardiganshire. The earliest evidence connecting him with Talley appears to be a charter of Edward III. which confirms certain possessions to the house, and refers to "Rhesius Magnus" as the first donor. It is thought that, of those who bore the name of Rhys, Rhys ap Gruffydd best deserves the surname "Magnus." It is clear that the abbey was well established by the early years of the thirteenth century, because about 1214 Gervase, abbot of Talley, became Bishop of St. Davids.



It is known that Strata Florida was a refoundation by Rhys ap Gruffydd of an older house. About two miles to the south of the ruins of the Cistercian monastery may still be seen the remains of the Hen Fynachlog. In like manner the abbey of Talley, whose ruins we see to-day, may very probably have been a refoundation of some earlier institution, because a daughter of Gwaethcoed-Vawr, prince of Caradigion, is referred to as abbess of Tal-y-llychan (Talley) a century earlier than the date of Rhys ap Gruffydd's foundation.

In the twelfth century the Benedictine had for about five hundred years been the sole monastic rule in Europe, *i.e.* it was the generally accepted rule of life for the "religious" in the technical sense of the term—for those, whether priests or laymen, who wished to devote themselves to God's service in a life of voluntary poverty, chastity and obedience. The other chief rule of life up to the twelfth century was the Augustinian. This was intended for clergy engaged in the active work of their calling, and was named after the great Bishop of Hippo, who in his house had gathered clergy round him, and, forming a community, in the same sort of way in which the Community of the Resurrection has been formed in our own time, with them lived a disciplined life. It cannot be said that St. Augustine founded an Order, but he set an example of community life for the clergy which was widely followed, and those who adopted it were known as Augustinians. Thus it came about that canons of cathedrals (not of Benedictine foundation) and of collegiate churches lived under the Augustinian rule. In process of time, just as slackness and luxury crept into the Benedictine monasteries, so too the Augustinian canons became less fervent in their devotion and more worldly in their manner of life. The twelfth century, however, was a time of religious revival. It saw the rise of the great Cistercian Order, which was a reformation from within of the Benedictine—a stern attempt to recall it to its original strictness of life. The same period also witnessed a like attempt to reform the Augustinian rule. The reformed Augustinians were known as Premonstratensians, so called from their first house at Premontré, near Laon, in Northern France. To this Premonstratensian Order Talley Abbey seems to have belonged. The Order was introduced into England about 1146, but there were not at any time more than about thirty-six houses belonging to it in our own country, and Talley was the only abbey of the Order in Wales. That the Premonstratensians never became a very popular or wealthy community in this country may be due to two things: first, their houses were subject only to the Abbey of Premontré, the mother house of the order, and therefore were in this land something like foreign outposts, upon which the Britisher, with his characteristic insular prejudice,

Digitized by Google



looked with suspicion; and, secondly, there arose amongst the Premonstratensians no commanding personality or great organising genius to do for the Order what St. Bernard did for the Cistercians.

To come to the buildings at Talley. The plan of the church is of the Cistercian type. In its rectangular and aisleless chancel and in its range of chapels on the east of the transept, it shows the peculiar features of a Cistercian abbey church, and almost exactly resembles Strata Florida Abbey in Cardiganshire. How shall we account for this if we are right in assigning Talley to the Premonstratensian Order? Giraldus Cambrensis tells of the ejection of Premonstratensian canons by the Cistercians in a certain place. The canons appealed to Hubert, Archbishop of Canterbury, and eventually regained their house. Now Hubert was Archbishop from 1193 to 1207, and the Premonstratensian canons referred to must be those of Talley, since there was no other house of the Order in Wales. It appears, therefore, that at the very time when this church was being erected there was a dispute for the possession of it between the two Orders, and for some time while the building was going on the house was in

RUINS OF THE CENTRAL TOWER, TALLEY ABBEY, CARMARTHENSHIRE.

the hands of the Cistercians. May not this account for the Cistercian ground plan of the abbey church at Talley? At the dissolution of the monasteries it was decided to use the abbey church for the parochial services, but as the whole church was much too large for the population and would prove too costly to maintain and keep in repair, walls were built within the church enclosing part of the choir and four bays of the nave, but excluding the transepts by blocking the north and south arches beneath the central tower. The rest of the building must speedily have fallen into decay, but the fragment around the central tower continued to be used as the parish church down to 1722, when even this was found to be too costly a building to maintain in sound condition. A new church was, therefore, erected to the north of the abbey, where, though since much altered, it still stands, and the stones of the abbey were used for the new building. As a ruin the great church lingered on, gradually getting less through being used as a quarry for structures in the neighbourhood or through natural decay. It was in 1845 that the last considerable fall of masonry took place. There is now so little left, save the shell of the central tower, that to attempt to reconstruct the church from the mutilated fragments might seem like setting out to reconstruct some prehistoric monster from a shattered bone, but from what we know of its history and through excavations conducted under the direction of Mr. Stephen Williams, F.R.I.B.A., of Rhayader, we are able to venture upon the task. The church was cruciform in plan and of great size—the nave alone was 145 feet long and had eight bays, one bay more than that at Strata Florida. There were six chapels to the east of the transept, three to the north of the central tower, and three to the south. A doorway gave access to the church in the north wall of the north transept, and near this may be seen the lower part of a spiral staircase leading to a passage which must have passed above the chapels of the north transept and thence to the belfry. This passage may still be traced in the remaining walls of the tower. In the south wall of the nave are traces of doors which must have led to the cloister. The domestic buildings at Talley were to the south of the church, as at Strata Florida; their site, however, has long been occupied by other buildings and has not been excavated, so that their outline cannot now be determined.

TALLEY ABBEY—PLAN.

We are told that in the excavations conducted here no carved stone-work of any kind was discovered. The building seems, therefore, to have been quite plain, the walls of rubble plastered over. When the church was built (*i.e.*, at the close of the twelfth and beginning of the thirteenth centuries) the prevailing style of architecture was the transition from the round-arched Romanesque to the early Pointed style, or perhaps the earliest form of Pointed which is generally known as Early English. Pointed arches were evidently used by the builders of Talley for construction—*i.e.*, where there was any great weight to be supported. Thus the arches at the base of the central tower are pointed; so, too, probably were the arches dividing the nave from the aisles. Some of the smaller openings, however, such as doorways and windows may very well have been round-headed, a conjecture supported by the fact that the small belfry-light still remaining in the east wall of the tower has a semicircular head. In the

Digitized by Google

Transition period we often find the round arch thus retained for smaller openings, while the pointed form is used in the main structural arches of the building, as, *e.g.*, at Kirkstall Abbey (Yorks) and Buildwas Abbey (Salop). Talley Abbey was evidently an example of what may be called the Early Welsh Cathedral or Collegiate type, belonging to the same class as the still complete Early-Pointed churches of Brecon Priory and Llanbadarn-Vawr, and the later churches of the same general plan at St. Asaph Cathedral and Laugharne (Carmarthenshire). The typical feature of these churches is the great area covered by the central tower. The enormous size of the tower at Talley may still be gathered from its ruins; it measures 38 feet across at the base and must have been, in its proportions, second only to the tower of St. Asaph Cathedral amongst the church towers of Wales. Upon the outer face of the remaining walls of the tower may be seen the marks which show that the pitch of the roof has been altered several times. Upon the east wall are three such marks. The loftiest of these three chancel roofs was no doubt the earliest, and the lowest is the latest in date, indicating the level of the roof of that part of the choir which, after the dissolution of the abbey, was walled in and retained for use as the chancel of the parish church.

From what has been said it is clear that Talley Abbey must have been a very impressive church, though not because of any elaborate carving or rich adornment, but simply from its noble proportions and massive grandeur. Especially, when viewed from without, must its tower have stood out boldly like a great fortress, as though intended as a reminder to men for all time of where their true refuge and strength lay. Even now, as we gaze upon its battered ruins, we must be impressed by it; its message can scarcely go unheeded, and we are constrained to exclaim:—

Guardian and monitor of all our days
Like fortress stern, thou bad'st men hope and dare.
Thy bells as angel-voices word on word
Chiming with sweetest music in the air
Called up men's hearts to Heaven, that they might praise
The tower of hope eternal—Christ the Lord.

EXETER CATHEDRAL.

THE Dean and Chapter of Exeter have issued a lengthy statement in explanation and defence of the steps they have taken to preserve the fabric of the cathedral, in the course of which they state:—

In the seventies of the last century, under the direction of the late Sir Gilbert Scott, a sum of 48,100*l.* was spent on the restoration of the cathedral, principally of the interior. Since that time further sums amounting to 22,307*l.* have been expended on the fabric, the organ, and the bells, exclusive of a very large amount, the gift of the late Mr. Willey, for the installation and fittings of the electric lighting of the cathedral and chapter-house. During the same period a further sum of about 10,500*l.* has been given by generous benefactors for stained glass, thirty-four windows in all, by the first artists in glass of the day, so that no less a sum than 80,907*l.* has been spent during the last thirty-five years on the cathedral. A further sum of 7,000*l.* is now wanted to complete the arrest of decay and safety of the cathedral and the beautiful chapter-house, which, as well as the cathedral, requires very careful attention.

The late Mr. Pearson in 1891 made a very thorough survey of the cathedral. He reported unfavourably of its then condition, having during his most careful survey detected much decay in all directions—more than he had anticipated—and he foresaw the spread of this decay. At the same date an independent report was made by Mr. Harbottle. Both reports are in our office; their agreement remarkable. We have been and are acting under the direction of the greatest architectural authority of recent times, supplemented by the knowledge and experience of one who is in daily touch with the fabric, and knows from long observation its real condition and its wants, and whose judgment thereupon was endorsed and approved by the late Mr. Pearson in 1891.

But we have a further advantage. When the great west window, on the insertion of the Temple Memorial glass, was dealt with, we had the advantage of the advice of the late Mr. Bodley, who thoroughly approved of the restoration of the stonework done under the direction of Mr. Harbottle. It was fortunate that the work was undertaken when it was; it was a remarkable instance of latent dangerous decay. If all this had not been detected, and the window had been left to itself, it would inevitably before long have fallen out, to the great injury of the western screen. It was most carefully dealt with, and every inch of the old stone which was preservable was used again.

It may be well here to give a brief statement of the recent work done on the great south tower. Here again we had a remarkable instance of latent dangerous decay at work, spreading and alarming, revealing itself, and it may not be amiss to remark that apparently when ancient stonework arrives at a certain stage of decay it is impossible to calculate the rapidity with which the decay will spread and the stonework enter upon its last stage of ruin. This depends much on the nature of the stone used, and the situation of the decay.

In the great south tower, settlement having been noticed, a thorough examination was made by Mr. Harbottle. The foundations of the walls were found to be of loose, badly built rubble masonry on black soil at a depth of about 4 feet 6 inches. The loose ground was removed at short stages to a hard gravel foundation, and the walls underpinned by a substructure of Portland cement concrete. Deep graves were found against the walls of the foundations. The walls of the tower above the ground level are built with two ashlar freestone faces—one on the inside mainly of plain squared stone, those outside the exterior of the richest description of Norman ornament. The total thickness of the walls varies from 8 feet to 6 feet.

The core of the walls is built of rubble masonry, which may be described as a filling between the two faces of ashlar stone. There appear to be very few bonding stones, and probably the face courses were laid first and the filling in followed.

The greatest structural defect was in the south wall, there being a crack quite 2 inches wide extending from about the level of the chapel roof to the top of the parapet through the whole thickness of the tower wall, thus allowing a great inroad for the weather; there were also cracks in the west wall of the tower. All these were carefully cut out and restored with sound ashlar, reusing as many as possible of the old stones. The body of the walls was grouted in with liquid cement injected under pressure, many tons of cement being used in the operations.

The south-east angle was found to be in a bad state. Here was originally the turret to the roof, which was at a later date filled in with bricks and mortar, with the result that the thin ashlar face suffered from the pressure brought upon it by the modern brickwork. All the bricks and mortar were removed where they were doing damage, and the back was properly rebuilt in stone, refixing the old ashlar and ornamental work so far as it was sound and suitable for reuse. Great care had been exercised in handling the old work. Wherever an old stone could be replaced it was marked and placed in its original position as a record showing how closely the new work is a careful reproduction of the old.

One of our great anxieties has been and is the great west screen; it is a priceless relique of the fourteenth-fifteenth century. But the problem before us is very difficult. No attempt has been made, nor will be made so long as I am Dean with the present chapter around me, to deal with the ancient figures of the west front; it is for their preservation that we are dealing with the canopies, niches, and other architectural surroundings; if these are not most carefully preserved nothing but featureless ruin awaits the whole front. We are doing our best in accordance with Mr. Pearson's directions, by careful attention to their weakened and crumbling surroundings, to preserve the ancient mystery of these featureless, mutilated figures, who, although so many of them are featureless and nameless, still speak to us of the past in language that we shall do our best to preserve.

We thought it was our duty to do our best to preserve all that was capable of preservation. Three courses were open to us—first, we might have left the west front untouched, on the plea that it was and always would be an interesting example of the architectural genius of the fourteenth-fifteenth centuries, however much it might suffer from the ravages of decay. This would have meant the disappearance at no distant date of its most prominent features, which would have been lost to posterity as a witness of the past. The second course was to treat the stone with certain well-known chemical solutions. Had the decayed stone been of a different nature, in a different condition, and in a different position we might have been advised to do this; but the nature of the decayed stone, its present condition, and its exposed position, were against such treatment. The third course open to us was to follow the advice of the greatest architectural authority of the day, who had the completest knowledge of the whole fabric and of the state of decay prevalent throughout. We followed, and are following, this

Digitized by Google

third course unwaveringly, and with increasing confidence, because every fresh revelation of decay year after year confirms the accuracy of his judgment and the wisdom of his foresight.

The problem is very difficult. The decay is deeper, far deeper, than is generally suspected.

The great north-western pinnacle, which has sometimes been spoken of as a perfect specimen of the fourteenth-fifteenth century, is only very partially original; the carved heads were comparatively modern, and were stuck on as terminals to the crocketted rolls of the pinnacle, the foundation of the pinnacle with its panels being stuck against a core of loose rubble, and formed of pieces of stone sometimes called "shiners," which were not structural. There was, indeed, very little of the pinnacle original, and as the panels were leaving the core and all leaned towards the west, and as decayed pieces had frequently fallen, the chapter were advised that it was very dangerous. It has been replaced in solid and very beautiful stone, which is rapidly toning to a soft grey, and such of the original parts as could be reused have been carefully replaced.

The restoration of a portion of the parapet of the sculptured front. Repairs to the south-west turret. Restoration of one panelled and crocketted buttress at the south-west end of the screen. Restoration of two panelled and crocketted buttresses at the south-west end of the screen. Restoration of two carved canopies at the south-west end of the screen, and securing the figures. Restoration and repairs of the carved canopies, panelled and carved shafts and cornice to south-west portion of the screen. Restoration of canopy and of the panelled and crocketted shaft. Securing figures by copper bolts. Restoration of south-west angle of north-west buttress and canopy on south-west of same, and repairs to the canopies of niches. In hand: Repairs to sculptured parapet of north section.

We have decided to introduce a magnificent stone, very similar to one with a slightly reddish tone largely used by the original builders. Observing that the stone with the reddish tint had stood the lapse of time and the assaults of weather, still retaining its chisel life and beauty, we naturally sought for a stone similar in character. We found it at Ketton, near Stamford; it has a slightly yellowish tinge which very rapidly on exposure tones into a delicate grey. In a few years the slightly yellowish tinge will have passed away. One of our most eminent sculptors, who has handled it in situ on the west front, an artist of the highest rank says, "It is a magnificent stone for the purpose, and the carving of it is admirable." The same stone is being used exclusively at York Minster, and for all the figure carving at Beverley; it is being largely used on many important buildings in Cambridge; was exclusively used for the very fine clock tower at Leicester; it is largely used for churches in Norfolk and Suffolk, and has been used for similar purposes for 400 years.

Our beautiful chapter-house, the work of Bishop Briwere the Crusader, who founded the deanery in 1225, and of Bishop Lacy, 1420, who was chaplain to Henry V. at the battle of Agincourt, and, therefore, probably one of those who in the early dawn of that great day gave the Blessed Sacrament to the army, has for some years caused us grave anxiety. This came to a head in 1902, when it was observed that the mullions of the great east window, a fine specimen of Bishop Nevylle's Perpendicular work (1456) were very insecure and out of the straight, and the head of the window evidently suffering from pressure. On examination it was found to be in a very serious state, and leaning to the west with an iron bar let into the transom. It was taken down stone by stone, each stone being marked and carefully reset in its original position if sound, and at the same time some old heraldic glass which had been found was carefully arranged in the windows. In the following year a serious defect was observed in the western gable, which was leaning away from the beautiful roof, the work of Bishop Bothe in 1465, so that the daylight was visible; the whole gable down to the springing of the arch of the western window was insecure. It had been badly built or restored of old stone previously used, and there were no bond stones; it is a marvel that it had stood so long. In the year following all the battlements on the north side were found to be in such an unsafe state that they were taken down and laid on the flat roof, where they remained for some time, but they have since been securely replaced; and last year all the beautiful Perpendicular windows on the south side were found to be in a very bad condition; we were obliged to remove one label which was hanging away from the wall in several places. The tracery and mullions are in a very dangerous and decayed condition, and last month the mullions of some of the windows on the north side were found to be in such a condition that it was not thought advisable to clean the windows. This is the next work to which we must turn our attention.

The following short summary will disclose our present position of need:—Required for the completion of the great west front, 2,245*l.*; for the chapter-house, 700*l.*; for general work on the roof, pinnacles, battlements, buttresses, windows, &c., 3,955*l.*; total, 6,900*l.*

BRASENOSE COLLEGE, OXFORD.

By John Buchan.

BEFORE the sixteenth century, between the High Street and Brasenose Lane, and encroaching on the ground which is now the Radcliffe Camera, stood a cluster of little halls with gardens to the west of them. There was Brasenose Hall and Little University Hall, Salisbury Hall and St. Mary's Entry, Little Edmund's and Haberdashers', Black Hall and Glass Hall. They were owned as a rule by larger colleges like University and Oriel, or by religious bodies like the Canons of Oseney; but Brasenose Hall was an independent community with a master of its own. The old Aula was not a college in the strict sense, but rather a community of students who chose to lodge together and framed a few simple rules for their Society. For long the Halls were not subject to University discipline, but were simply academic hostelries—places of lodging rather than of learning. Many of them had a sign like an inn over their doors, and this undoubtedly was the origin of the famous Brazen Nose. As Antony Wood says:—"The College was now finished out of the ruins of several hostels, the chief of which was Brasenose Hall, so called without a doubt from such a sign which was in ancient times over its door, as other Halls also had—namely, Hawk or Hieron Hall, Elephant, Swan or Black Hall." So the derivation of the name from Brasinium or Brewing-House may be confidently discarded. When early in the fourteenth century many Oxford clerks migrated to Stamford, in Lincolnshire, the students of Brasenose Hall held together and had a house of their own, which argues that a certain solidarity had been reached in the little organisation.

The Hall grew into a College early in the sixteenth century, and the pious founders were William Smyth, Bishop of Lincoln, who was Chancellor of the University from 1500-3, and Sir Richard Sutton. The little Halls were bought up or leased on a long term, and in 1509 the foundation-stone of the College was laid. The stone came from the famous quarry on Headington Hill, and the building began in the south-west corner of the Old Quadrangle. The College was not, like Corpus Christi, the result of the new learning, but apparently designed as a protest against it and as a sanctuary of the old tradition. The Hall had drawn its students mostly from the North Country—the part least influenced by the new movement—and the College continued the custom of the Hall. The charter of foundation is dated 15$\frac{11}{12}$ and the first statutes were completed in 1514. At first there was only one quadrangle of one storey and garrets, with a tower over the gate which contained the Principal's lodgings. The chapel was a little oratory on No. 1 staircase where is now the senior common room. It was not till the time of James I. that a second storey was added, an addition which did not, as at New College, spoil the proportions of the old buildings.

Entering the College by a gate opposite the Radcliffe Camera we find ourselves in the Old Quadrangle. The centre is filled with grass, but at one time there used to be an elaborate maze, which may still be seen in Loggan's view of the College in 1675. The maze was removed in 1727 and its place taken by a statue of Cain and Abel, painted a staring white, which was a source of temptation to festive undergraduates. It purported to be by John of Bologna, but was almost certainly an indifferent copy, though its removal remained always a sore point with Walter Pater. In 1881 grass replaced it, and to-day the Old Quadrangle is a very pleasant, green, well-proportioned place. The great chestnuts in Exeter Gardens, the dome

Digitized by Google

of the Radcliffe, and the towers of All Souls make an effective background to its staid simplicity.

On the south side is the Hall, which remains much as it was at the foundation. Till the middle of the eighteenth century the fireplace was an open one in the middle of the floor, and the louvre is still there, though hidden by the ceiling. The present handsome chimneypiece was presented to the College in 1760 by Lord Curzon. The north window at the east end contains portraits of Smyth and Sutton, the founders. The south window was placed there to commemorate the visit of Louis XVIII. of France, who lunched in the Hall with the Principal and Fellows. None of the pictures on the walls are remarkable, but the little one of Alexander Nowell depicts the Dean of St. Paul's with his fishing tackle around him, and has had the honour of being described at length by Isaak Walton.

Passing below a dark archway to the left of the old gate we enter the second Quadrangle, which dates from the middle of the seventeenth century. It is a quaint little place, planted with shrubs, with the library on the east, the chapel on the south, and the kitchen on the west. For some reason which I have never been able to discover it is known as the Deer Park. The eastern side used to be cloisters below the library, but early in the nineteenth century, when residence in College was made compulsory, the cloisters were turned into rooms. The chapel was built from 1656-76, and is ascribed by tradition to Sir Christopher Wren. It is chiefly remarkable for its roof, which is a fine piece of fan tracery, said to have been brought from the chapel of St. Mary's College. It was certainly brought from somewhere, for it does not quite fit. The architecture is an agreeable mixture of Greek and Gothic, and though it cannot be compared with the more famous Oxford chapels, it is a good example of its period. The library, which adjoins the chapel, belongs to the same date, and is attributed to the same architect. The old library used to be on the north side of the Old Quadrangle, which is now used as a lecture room. The kitchen and buttery are among the oldest parts of the College, and in the latter may be seen the portrait of the Lancashire giant, the "Child of Hale," after whom the Brasenose boat is always named.

South-west of the Deer Park is the New Quadrangle, with a gate opening on the High Street. It is filled with grass plots and flower beds, and the bare spaces between make a convenient site for bonfires. Early in the eighteenth century the College bought up the old houses between St. Mary's Entry and All Saints Church, and began to talk of a front in the High Street. Nicholas Hawksmoor—the same who built the High Street front of Queen's—submitted designs for the work in the same style, which are engraved in Williams's "Oxonia." They were singularly inappropriate and were fortunately rejected. The project languished for nearly a century, till Sir John Soane prepared designs again in 1807. Nothing came of them, and it was not till the eighties that the College employed for the work Mr. T. G. Jackson, who has done so much to preserve the peculiar charm of Oxford. By 1887 the New Quadrangle had been built in the Gothic style, which harmonises well enough with the old buildings. On the High Street front there is a gateway and tower with the Principal's House—a very handsome building—on the east of it. On the other side of the Quadrangle is the new junior common room, and facing the chapel is a large block of buildings occupied by undergraduates' rooms. There is still a little gap at the south-west corner which leaves the Quadrangle incomplete, and it is to be hoped that this space may shortly be filled up.

The interest of Brasenose is not architectural, save in so far as it is a typical example of the smaller sixteenth century collegiate foundation. The Old Quadrangle is in its own way as perfect as any in Oxford. But the situation of the College in the very heart of the city, surrounded by many stately neighbours, lends it adventitious charms. If it lacks gardens and greenery it has a rich environment of its own, for in any view—more especially from the Old Quadrangle—the chestnuts of Exeter, the huge tower of the Bodleian, the great dome of the Radcliffe, the spire of St. Mary's, and the pinnacles of All Souls are part of the scene. Walter Pater appreciated this aspect of the College, for he used to defend bonfires in the Quadrangles on the ground that they cast a beautiful glow upon St. Mary's spire.

ILLUSTRATIONS.

LIVING ARCHITECTS.—NO. 16, MR. G. H. FELLOWES PRYNNE, F.R.I.B.A.

MR. G. H. FELLOWES PRYNNE has attained the position of being one of the foremost of the Church architects of the present day. He has had the good fortune to have clients who usually have not expected a good building for an inadequate sum. He has been a very popular President of the Architectural Association.

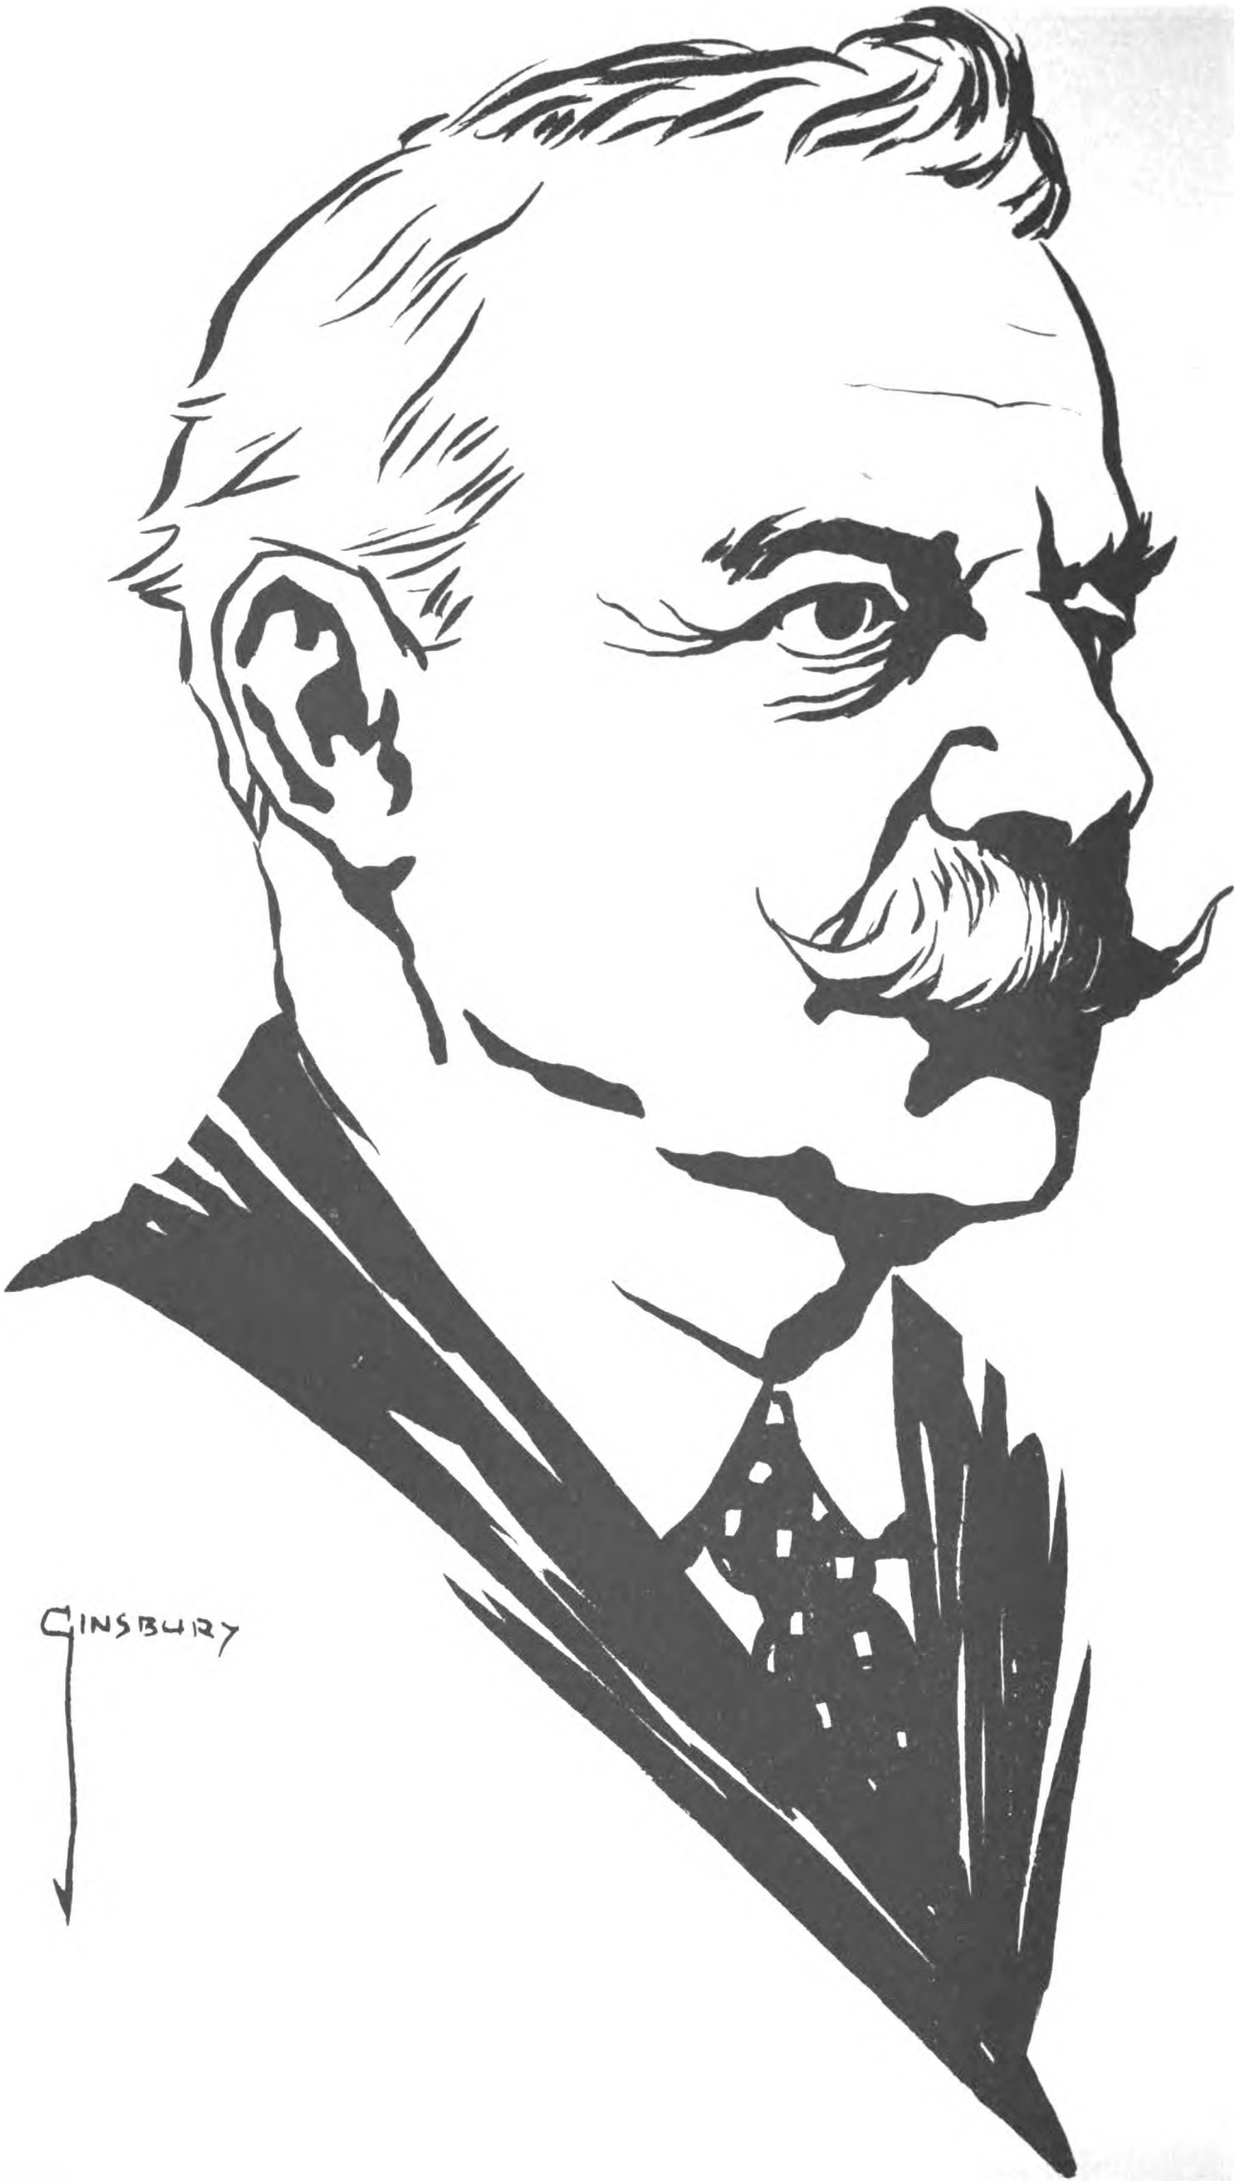
NO. 17, MR. WILLIAM A. PITE, F.R.I.B.A.

MR. WILLIAM A. PITE had made his mark repeatedly in open competitions, and has now by his work at the new King's College Hospital become enrolled amongst our acknowledged experts in hospital planning.

ST. CHAD'S CHURCH, FAR HEADINGLEY, LEEDS.—NEW CHANCEL AND VESTRIES.

IMPORTANT additions and alterations are in course of erection at the eastern end of St. Chad's, Headingley. The circular apse, which proved inadequate to the needs of the parish, has been demolished, and, when the present works are completed, will be replaced by a new choir and square-ended sanctuary of the same height and width as the nave. A choir-vestry, organ-chamber, and porch are being added on the south side, and on the north a clergy-vestry and chapel. The two sides are connected by a passage cut in the thickness of the east wall. All the stonework of the old walls has been reused in the extensions. The ground slopes sharply away on the north and east sides, thereby giving the lofty effect that is noticeable in our illustration. Horsham stone is being used both externally and internally. The wall surfaces are to be plastered. It is hoped to decorate the ceilings, also to introduce colour in the fittings and gild the grilles. This design was selected in a limited competition last year by Messrs. Nicholson & Corlette, the assessors. The perspective was hung in the Academy. Messrs. Wilson & Sons, of Leeds, are the builders. Messrs. John Gibbons & Son are the architects.

SECOND PREMIATED DESIGN FOR BERKSHIRE COUNTY COUNCIL OFFICES, READING.



IN the accompanying design by Mr. E. J. Shrewsbury the various departments are arranged on separate floors and in distinct blocks, and direct communication is provided for between the heads of each department and their assistants. All the general offices and waiting-rooms are close to the main staircase and lift, which are centrally placed, immediately opposite to the entrance. A secondary staircase is provided from the first to the third floor.

Access to the Assize Court from the new buildings is arranged on the ground floor and also on the first floor.

The committee-rooms are so placed as to be in direct communication with the Court.

Both rooms have a considerably larger area than is required by the conditions, and the education committee room is arranged to be divided into two rooms, each having its own fireplace and entrance door. The provision of central areas allows for efficient lighting and ventilation of the whole of corridors and lavatories. Separate cloakroom and lavatory accommodation is provided for (1) Members of committee, (2) officials and staffs of the various departments, and (3) ladies. The caretaker's apartments are placed in the basement, with a separate entrance. Storage for forty bicycles is also obtained in the basement, with a separate entrance, and so arranged that all machines can be separately placed. For the elevations Lawrence's Bracknell facing bricks would be used, with Portland stone dressings, the roofs to be covered with Tilberthwaite Westmoreland bright sea-green slates. The floors to be in reinforced concrete with metal lath ceilings suspended under. The buildings throughout to be warmed by radiators, fireplaces also being provided in all principal rooms and ventilating flues carried up in chimney stacks.

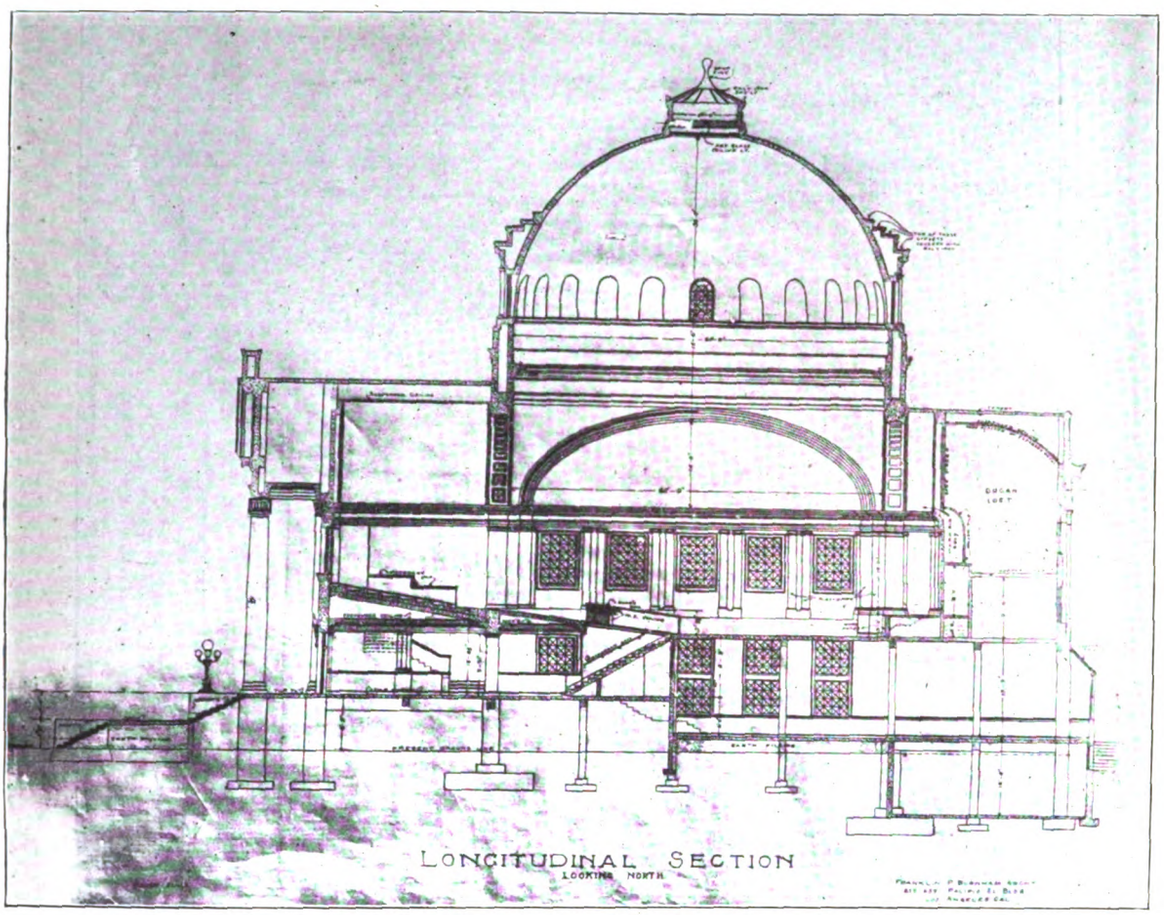

Fig. 1.—CONCRETE CHURCH, PASADENA.

A CONCRETE CHURCH, PASADENA, CALIFORNIA.

THERE is now being constructed in Oakland Avenue, Pasadena, California, by the members of First Church of Christ Scientist, a reinforced concrete church, the design for which presents many unusual features. The walls, floors, footings, beams, columns, stairs, dome, cornices, and all projections and ornamentations and entire roof construction are of reinforced concrete.

The detail of the structure is based on the Grecian Ionic style. The site is 4½ feet above the street level. The building is 120 feet by 120 feet, and when completed will be one of the finest edifices owned by this denomination, noted for its beautiful churches. The simple lines of the construction will make it one of the most distinctive in Pasadena. Fig. 1 shows the section, fig. 2 the main floor, fig. 3 the ground floor, and fig. 4 the perspective view of the building when finished.

The ground and auditorium floors are of the general slab and beam construction, with ordinary Kahn tile floor 14 to 17 feet floor spans and beams 18 to 24 feet. The floors are carried by columns which extend down to concrete footings. The building rises to an extreme height at the top of the dome 93½ feet. The dome itself is hemispherical, with an interior diameter of 60 feet, and has at its top a lantern with a diameter of 10½ feet internal measure. The dome will be constructed of a reinforced concrete shell varying in thickness from 4 inches at the lantern to 8 inches at the foot of the dome, the dome resting directly on the ring, which is itself 2 feet deep. The ring in turn is carried by four reinforced concrete arches of 60 feet span and 14 feet rise; these arches will be 3 feet wide throughout their length and 2 feet deep at their crowns. These four arches are carried by four columns 36 by 36 inches, reinforced with twelve 1 inch square bars. The four columns supporting as they do the entire roof construction, including dome, arches, &c., extend down through the auditorium and ground floors and rest on 14 by 14 feet reinforced concrete footings. The distance from the auditorium or upper floor to the crown of the dome is 79¼ feet.

A feature of the plan is the grand foyer, from which five external entrances will open; four stairways lead from the foyer to the auditorium above, and two entrances open into the Sunday school-room, which has a seating capacity of 800 persons. The auditorium will seat 1,400 persons and is well lighted through twenty-four windows of white cathedral and amber glass. Throughout the interior the finish of the building will be of white enamel, the doors being of mahogany. The exterior finish will be made by plastering with a thin coat of cement mortar made of marble dust and La Farge cement, and lined off to represent stone blocks, which will have the effect of a white marble structure. Franklin P. Burnham is the architect, Jay B. Harris structural engineer, and F. O. Engstrum Company are the contractors. The building is well advanced, the floors are in place, and the work is now progressing on the four 60 feet arches under the dome.

THE CORROSION OF IRON.*

IT is well known that iron readily corrodes when exposed to the action of liquid water and air at ordinary temperatures. At first this was regarded as a simple case of oxidation, similar to that which obtains when iron is heated in air. We now know, however, that the reaction is more complex, and several theories have been suggested by way of explanation. Of these there are two only which merit consideration here, for the others have already been proved to be untenable. These are what are known as the acid and electrolytic theories respectively.

According to the former, as its name implies, pure water, oxygen and iron may remain in contact with one another for an indefinite period without the formation of rust. The presence of a trace of some acid to act as catalyser is absolutely essential if oxidation of the metal is to begin. As carbonic acid is very prevalent in natural air and water, we may asume that in all ordinary cases of rusting it is this acid which acts as the catalyser, by attacking a portion of the iron, forming ferrous carbonate, $FeCO_3$, or perhaps the soluble ferrous hydrogen carbonate, $FeH_2(CO_3)_2$. This is then converted into rust by the oxygen of the air with the

* A paper read at the autumn meeting of the Iron and Steel Institute, by J. Newton Friend, Ph.D., M.Sc. (Darlington).

Digitized by Google

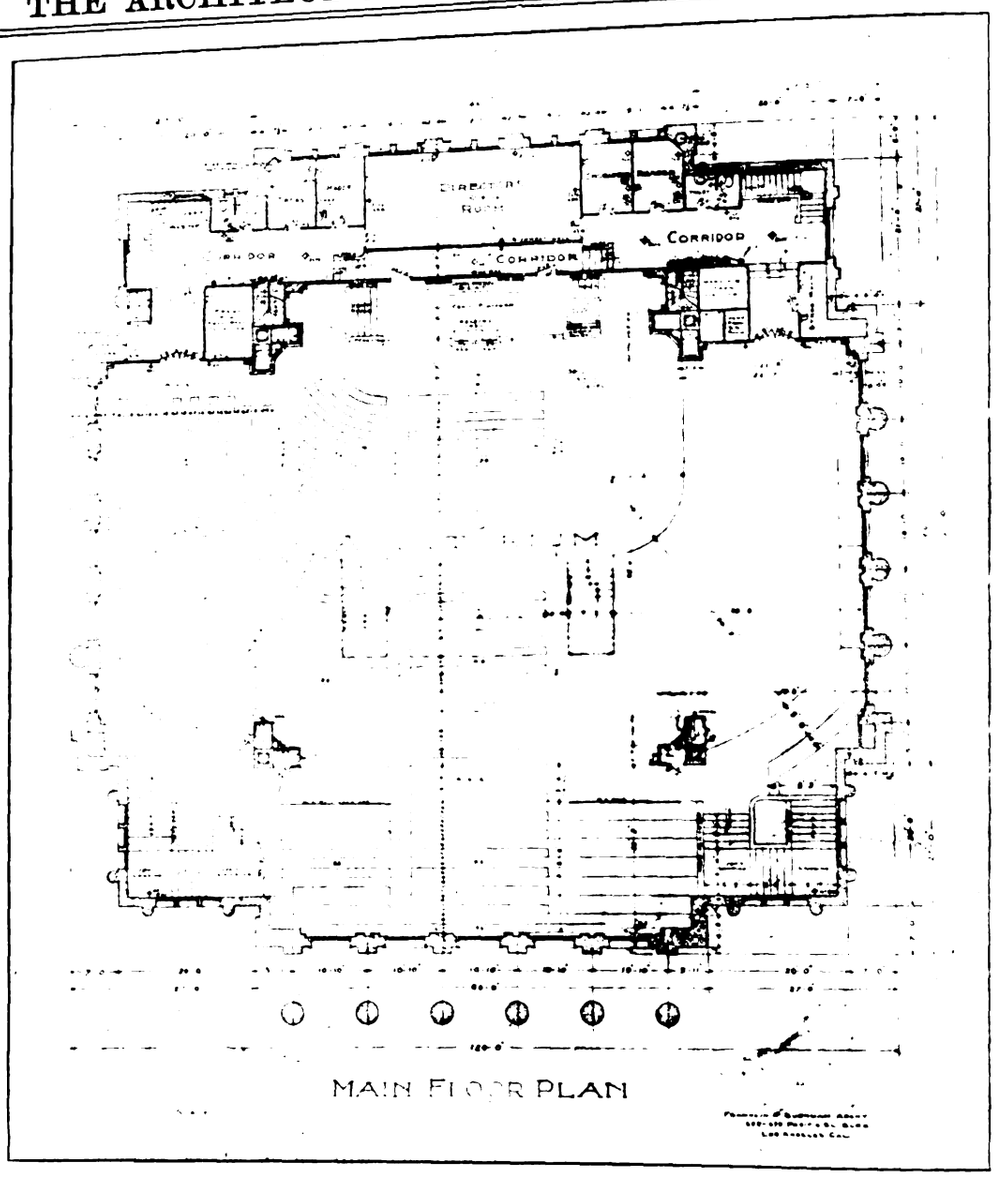

Fig. 2.—CONCRETE CHURCH, PASADENA.

simultaneous liberation of carbon dioxide, which is now free to attack a fresh portion of the iron. We thus see that an infinitesimal amount of carbon dioxide in the presence of water and oxygen would be capable of converting an indefinite amount of iron into rust.

I may, perhaps, at this point be allowed to take exception to Dr. William H. Walker's recent statement that I am a supporter of the so-called "carbonic acid theory of corrosion." This theory implies that carbonic acid is the only acid which can or does affect the corrosion of iron, whereas it should be well known that any acid capable of attacking iron is also effective. In my previous paper, already referred to, carbonic acid was cited for the reason given above. It is to the general "acid theory of corrosion" that the results of numerous experiments compel me to adhere, and the importance of bearing this distinction in mind has already been emphasised by Dr. Gerald T. Moody in a letter to *Nature* of March 7, 1907.

According to the electrolytic theory of corrosion, on the other hand, the presence of an acid, even in traces, is not essential to the oxidation of the iron, liquid water and oxygen alone being necessary. It is assumed that pure water is ionised to a small but definite extent, and that when a strip of iron comes in contact with it, positively charged iron ions are sent out into the water. Hydrogen ions simultaneously leave the liquid, which latter now becomes virtually a solution of ferrous hydroxide in water. Thus:—

$$Fe + 2H^{\cdot} + 2OH' = Fe^{\cdot\cdot} + 2OH' + H_2.$$

Addition of oxygen now causes the ferrous iron to assume the ferric condition, and rust appears.

It might appear at first sight that to decide between the two theories would be a matter of great simplicity, for the presence of an acid can readily be detected by means of certain reagents such as litmus and methyl orange. But further consideration shows that such is not the case. It has already been pointed out that, according to the acid theory, a single molecule of acid is sufficient to start the process of rusting, and certainly in practice a very small number would be able to produce a visible effect in a few hours. Remembering that several million molecules of an acid could be placed side by side in a line less than 1 centimetre in length, it will be clear that millions upon millions of such molecules would be necessary to respond to a colour test gauged by the naked eye. Hence such a method breaks down at once. We are bound, therefore, to arrive at our conclusions in a more or less indirect manner, and hence arises so much uncertainty. In my previous paper I have given a detailed account of experiments performed in two glass bulbs connected together internally, but hermetically sealed from the air. One bulb contained sodium hydroxide, and pure CO_2-free water was distilled from it on to a strip of pure iron in the second bulb. It is a noteworthy fact that when the water was distilled from the $\frac{1}{30}$-normal sodium hydroxide solution the iron readily rusted, but when the alkalinity was normal no rusting took place, save at the edges in contact with the glass. This freedom from rust in the latter case is attributed by the advocates of the electrolytic theory of corrosion to the solution, by the distilled water, of some of the alkali from the glass, whereby the number of hydroxyl ions was increased and the number of hydrogen ions proportionately reduced. But if such was the case, the same source of alkalinity should have prevented the formation of rust when the $\frac{1}{30}$-normal sodium hydroxide solution was used. But it did not, and the explanation is thus seen to break down.

Digitized by Google

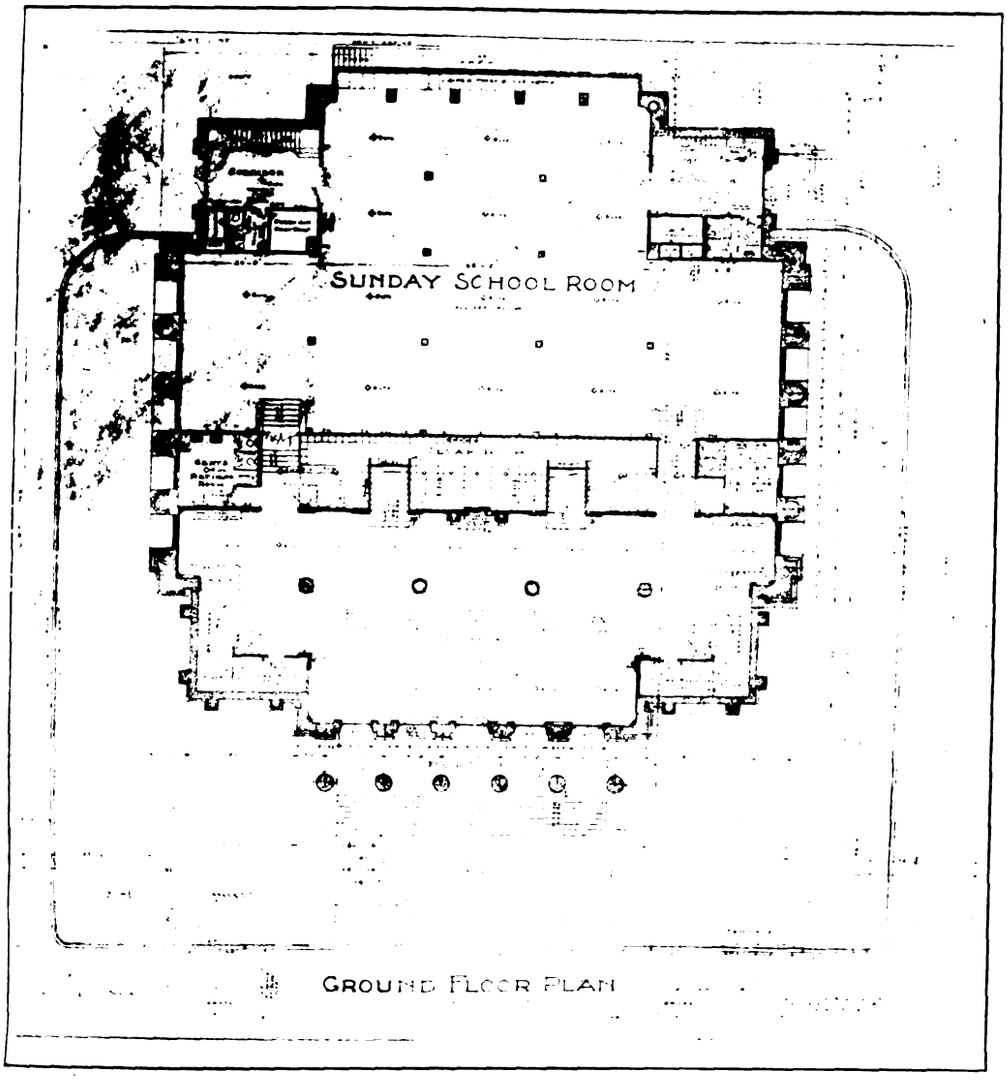

FIG. 3.—CONCRETE CHURCH, PASADENA.

According to the acid theory, on the other hand, a ready explanation is forthcoming. It need not, however, be repeated here, as it has already received full treatment in the paper referred to.

Again, in all experiments hitherto published, in which iron is said to rust in contact with pure oxygen and water, it is easy to show that sufficient precautions have not been taken to make the removal of all traces of acid an absolute certainty. Thus Tilden overlooks the fact that barium hydroxide has a very definite equilibrium pressure of carbon dioxide. He also assumes that by merely warming an exhausted glass tube every trace of adherent air can be removed from its surface. But numerous researches of recent date have shown that such is far from being the case. The experiments of Dunstan, Jowett and Goulding are open to similar criticism.

My experiments show, however, that when all the necessary precautions are taken corrosion does not take place. It seems to me, therefore, that the balance of evidence is decidedly in favour of the acid theory. In the paper already referred to, after quoting my statement "that the electrolytic theory of corrosion is untenable," Dr. Walker remarks that "if Dr. Friend's observation be correct, which the author does not admit—namely, that this small amount of carbonic acid is necessary to the solution of the iron—this fact does not contradict the electrolytic theory, but can best be explained, and in truth can be explained only, by the use of the electrolytic theory." It is clear that Dr. Walker fails to distinguish between "the electrolytic theory of corrosion" and what is generally understood by the "electrolytic theory" in its wider application. As we have already seen, the former is based on the assumption that water is ionised to a sufficient extent to cause the corrosion of iron in the presence of oxygen, even though no trace of acid is present. My conclusion is that an acid must be present. But I agree with Dr. Walker when he says that the acid theory of rusting is in harmony with the "electrolytic theory," where by that expression he refers to the theory as enunciated by Arrhenius in its widest sense. The criticism is thus seen to be based on a misunderstanding and falls to the ground.

It may be well to call attention at this juncture to the fact that the ionisation of water, which forms the base of the electrolytic theory of corrosion, is purely an assumption for which we have no definite proof. Kohlrausch showed many years ago that water offers the greater resistance to the passage of an electric current the more carefully it is purified. A limiting value can, however, be reached, below which the conductivity cannot be reduced. Kohlrausch and Heydweiller distilled water repeatedly in platinum vessels in vacuo, and determined the conductivity as soon as the water was condensed. At 18° C. the value was 0.0384×10 ohms per centimetre, from which we calculate the ionic concentration to be 0.78×10 gramme ions per litre. It is noteworthy that simple contact with air raised its conductivity tenfold in a very short time.

Now although this water was undoubtedly the purest which has ever been obtained, we have no proof that it was absolutely pure. Not a few chemists maintain that if absolutely pure water could be obtained, it would be found to be incapable of conducting an electric current—in other words, that it would be incapable of ionisation. Leduc has drawn attention to the extreme difficulty of removing every trace of dissolved gases from water by boiling, and a very few molecules of carbon dioxide would be ample to give to an absolutely non-conducting specimen of water the minute conductivity observed by Kohlrausch and Heydweiller; so that their results may simply be a measure of the extent to which the dissolved gases remain in solution under the special conditions of the experiments. If such is really the case, the electrolytic theory of corrosion becomes a myth, whereas the acid theory is unaffected by it.

Digitized by Google

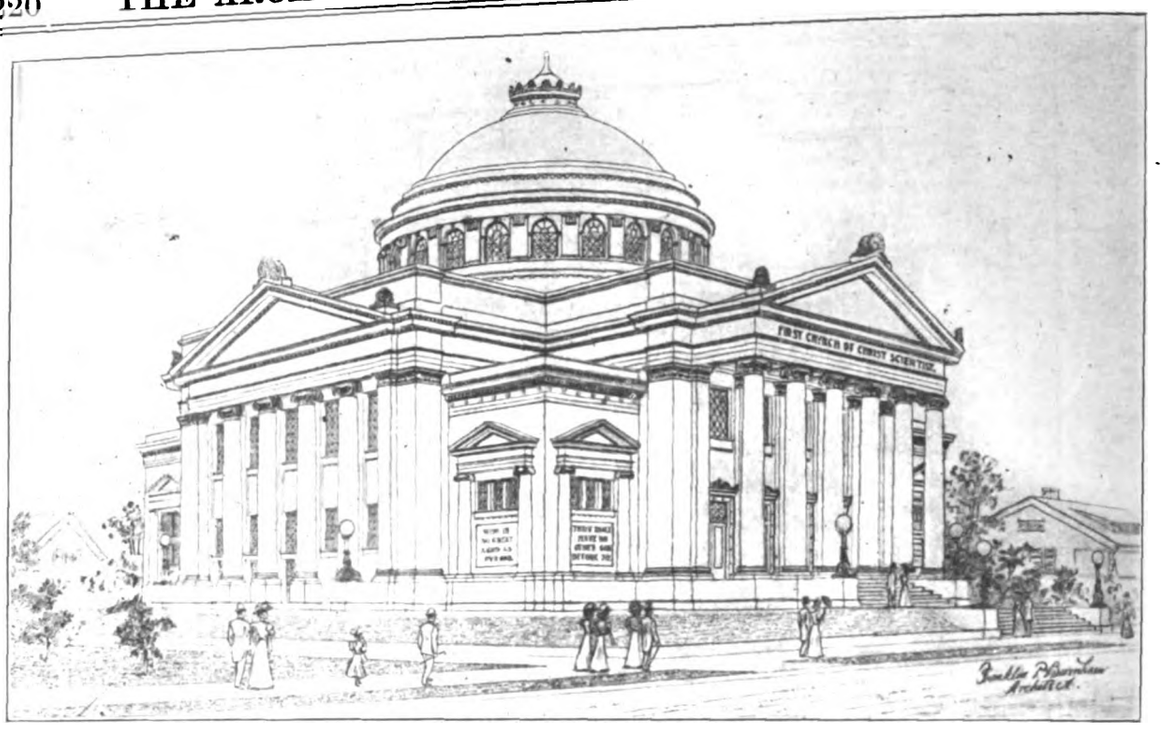

Fig. 4.—PERSPECTIVE VIEW OF CONCRETE CHURCH, PASADENA, CALIFORNIA.

In this connection I should like to draw attention to the fact that, whilst Dr. Walker's ferroxyl is undoubtedly a useful reagent when rightly used, no experiments with ferroxyl in actual contact with metallic iron can be quoted as deciding between the acid and electrolytic theories of corrosion, for its constituents are complex organic bodies which it is impossible to prepare in an absolutely neutral condition.

From the preceding remarks it will be clear that the whole question resolves itself into this:—Is pure water sufficiently active to effect the corrosion of pure iron in the presence of oxygen alone at ordinary temperatures, or is it not? Dr. Walker supplies the answer most decidedly in the affirmative, but my experiments lead me to an opposite conclusion. But either view is in harmony with the electrolytic theory of ionisation as we now know it, and the solution of the problem is one of theoretical rather than practical value.

ARTIFICIAL MAGNETIC OXIDE OF IRON.*

ONE more process, it would seem, must be added to the number of those that have had their inception in England, but which have been developed abroad. The Wülffing process, introduced from Germany, for the manufacture of a blue-black oxide of iron colour from ferrous liquors, of which an account was given to this Institute at the recent Vienna meeting, finds its parallel in a discovery of Dr. William Gregory which appears to have been lost sight of. It, however, in no way detracts from the merit of Dr. Wülffing nor from the value of the existing patents.

Gregory observed, that when a solution of protosulphate of iron is divided into two equal parts, one of which is peroxidised, then mixed with the other, and precipitated by ammonia at a boiling heat, a black oxide is obtained, which does not attract oxygen in drying, and is highly magnetic. Its composition, he continues, must be $2FeO + Fe_2O_3$; as the two solutions contain equal quantities of iron; and suggests that it may occur native as a variety of magnetic iron ore.

The above observation of Gregory's is not usually to be found in the small handbooks of chemistry excepting his own, wherein he has the following paragraph worthy of quotation in full:—

"*Magnetic Oxide of Iron.*—This oxide is the native magnet or loadstone, which is a heavy black mineral strongly attracting iron filings or steel. It is believed to be composed of protoxide and peroxide, and the native magnet is generally supposed to be $Fe_3O_4 = FeO + Fe_2O_3$. There is reason, however, to believe that another kind of magnetic oxide exists, which is $Fe_4O_5 = 2FeO + Fe_2O_3$. At all events, both of these compounds may be formed artificially, and both are magnetic as well as permanent, not absorbing oxygen or passing into peroxide. To prepare the former, take two parts of green vitriol; dissolve it in water and convert it into persulphate by boiling with nitric acid; then mix the solution with the solution of one part of the unaltered green vitriol, and precipitate the hot liquid by ammonia. A green precipitate falls which is to be washed and dried. The second magnetic oxide is prepared in the same way, only converting into persulphate one part of green vitriol instead of two parts. The precipitate is black if made in the liquid while hot. It is evident that in the latter case the quantity of iron, in the forms of protoxide and of peroxide, will be equal; in the former, the quantity of iron in the peroxide will be double that in the protoxide, so as to yield the above formulæ."

The paucity of information referred to may account for Gregory's observation not having found industrial application until recent years, and where the reaction is mentioned in one of the larger manuals it would rather deter one from attempting it on a big scale.

Thus it is stated that the hydrated magnetic oxide may be prepared by dividing an aqueous solution of sulphate of iron into three equal parts, peroxidising two of these with nitric acid, adding the other, and pouring the mixture, with frequent stirring, into an excess of solution of ammonia; if the operation were reversed, and the ammonia added to the mixture, the sesquioxide would be first precipitated, then the protoxide; so that a mixture and not a combination of the two would be obtained.

It will be noticed that this is quite opposite to the experience of Gregory, who adds the ammonia to the mixed liquors. But however the matter may be regarded the conditions of the Wülffing process have removed all doubt, for by the application of heat and pressure after precipitation, the desired combination is obtained, as is evident from the magnetic character of the product. A mere mixture of FeO and Fe_2O_3 would have no such property.

And here may be considered the fact that any of the black oxide obtained by this process is magnetic. The operation in actual practice is conducted by adding a portion of the ammonia to the ferrous liquor, which in Derby is the chloride, thus producing the lower hydrated oxide. By blowing air through the mass this lower oxide FeO is oxidised to the higher state Fe_2O_3. The rest of the ammonia is then added, sufficient to effect complete decomposition of the ferrous salt, and combination of the two oxides is brought about, as above stated, by means of heat and steam or air pressure, dehydration being at the same time effected.

It will be obvious that a mathematically exact division of

* A paper read at the autumn meeting of the Iron and Steel Institute, by F. J. R. Carulla, F.C.S. (Derby).

Digitized by Google

the ammonia is practically impossible, as is also the exact peroxidation by means of air of the first precipitated portion of the oxide. The resulting final product will therefore contain different proportions of FeO and Fe_2O_3 in every charge, a matter, however, of no practical significance when the process has been got into fair working order, the differences then not being great. The fact nevertheless makes the name ferroso-ferric oxide a peculiarly appropriate one if Gmelin's definition is accepted for these bodies, viz., those oxides of iron which contain more oxygen than the protoxide and less than the sesquioxide in various proportions.

Nevertheless, there is ground for believing that, generally speaking, combination occurs only between FeO and Fe_2O_3 to form Fe_3O_4, and that any excess of Fe_2O_3 remains in admixture as such. The reason for this opinion is that it is possible to obtain a great variety of colours quite as one might expect from mixtures containing varying quantities of the black magnetic oxide and of the highly coloured ferric oxide, as is shown in the annexed table, which gives the results of analyses of the first fifteen charges of the magnetic oxide produced at Derby whilst apprenticeship to the process was being served.

Formulæ of Charges.

No. of Charge.	Ferroso-ferric Formula.		Magnetic Formula.		Proportion of Magnetic to Ferric Units.	Colour.
	FeO Units.	Fe_2O_3 Units.	Fe_3O_4 Units.	Fe_2O_3 Units.		
1	5	7	5	2	2·5	Black.
2	7	9	7	2	3·5	Black.
3	4	5	4	1	4·0	Black.
4	4	5	4	1	4·0	Blue black.
5	11	20	11	9	1·22	Brown.
6	7	10	7	3	2·33	Brown black.
7	7	10	7	3	2·33	Blue.
8	8	9	8	1	8·0	Blue black.
9	8	9	8	1	8·0	Black.
10	8	9	8	1	8·0	Black.
11	5	8	5	3	1·66	Green.
12	3	4	3	1	3·0	Brown black.
13	7	8	7	1	7·0	Black.
14	6	7	6	1	6·0	Greenish black.
15	3	4	3	1	3·0	Blue
Dr. W.'s	5	6	5	1	5·0	Blue black.

In the table the various values are derived from the proportion of ferric to ferrous oxide found in the different samples, columns 2 and 3 giving the ferroso-ferric formula; thus charge No. 1 would be $5FeO + 7Fe_2O_3$. It is obvious, however, that this formula can rapidly be transformed into the magnetic formula—that is to say, the one more likely to be correct—by simply taking the units of FeO as units of Fe_3O_4, subtracting these from the units of Fe_2O_3, and regarding this remainder as peroxide in admixture. These numbers are given in columns 4 and 5. This view seems to quite accord with the analyses of magnetites in Dr. Stutzer's valuable table.

Column 6 gives the proportion of magnetic to ferric units, and it will be seen by the last column that where the magnetic units largely preponderate the colour is usually a decided black. Where the ferric units approximate in number to the magnetic the change from black is very decided, as in Nos. 5 and 11.

The last sample in the table, marked Dr. Wülffing's is a normal product of the process.

It may be mentioned that although the variations obtained may militate against the colour, as a black, they in no way injure it as a protective medium for paint purposes, Fe_2O_3 being quite stable.

It is from this point of view—that is, from its possible instability—that Fe_4O_5 might be thought to be a less desirable body to aim for in the process than Fe_3O_4. It is easy to conceive of Fe_4O_5 as a tertiary product obtained by the combination of Fe_3O_4 with FeO, in which case the ferrous oxide might be more lightly held than is the case in Fe_3O_4. If this were the case decomposition would more readily set in with Fe_4O_5 than with Fe_3O_4.

This may well be, however, an erroneous conjecture, for it will be found that whereas some of the samples, for the purpose of analysis, dissolve in acid* with the greatest ease, now and then one comes across an intractable body most difficult of solution. May it not be that in this case Fe_4O_5 is the body so resistant to chemical action?

Charges Nos. 11 and 15 were of this character.

It may be well to recapitulate, and possibly make more clear, the points that it is desired to emphasise in the above remarks, although Dr. Wülffing worked out its industrial manufacture from waste liquors—no small merit.

Firstly, that to William Gregory of Edinburgh must be assigned the discovery of the artificial production of magnetic oxide of iron. Of this there can be no doubt, as what seems to be the earliest notice of it is found in a book of which Liebig was co-editor and Gregory gets full credit for it.

Secondly, that there are grounds for believing that magnetic oxide of iron made by the above process is either Fe_3O_4 or Fe_4O_5, and that any variation from these formulæ is due to admixture of Fe_2O_3.

Thirdly, that to say whether the main portion of any sample is Fe_3O_4 or Fe_4O_5 is not a matter that can be asserted with certainty, although there are indications that two distinct bodies exist in different samples, one of these being most difficult of solution. This is a matter well worthy the attention of some competent investigator to whom the subject may appeal. Fourthly, that notwithstanding those difficulties that all beginners are sure to encounter, the product is difficult to spoil in the making, except as regards colour, and the operator can soon attain to the production of a commercially uniform article.

Finally, it may be added that the protective character of this magnetic oxide of iron is most marked. Just as the Bower Barff coating and the film on Russian sheet iron, both magnetic, afford protection to iron surfaces, so does this product when laid on in the form of paint.

The action that takes place through the localisation of scale on iron plates must not be thought to militate against the use of a magnetic iron paint. It might as well be argued that because a hot ember will burn a hole in the flesh, therefore diffused warmth must also be harmful.

The great protective value of what one may be allowed to call the Gregory-Wülffing magnetic oxide of iron paint is acknowledged by all who have had any experience of it.

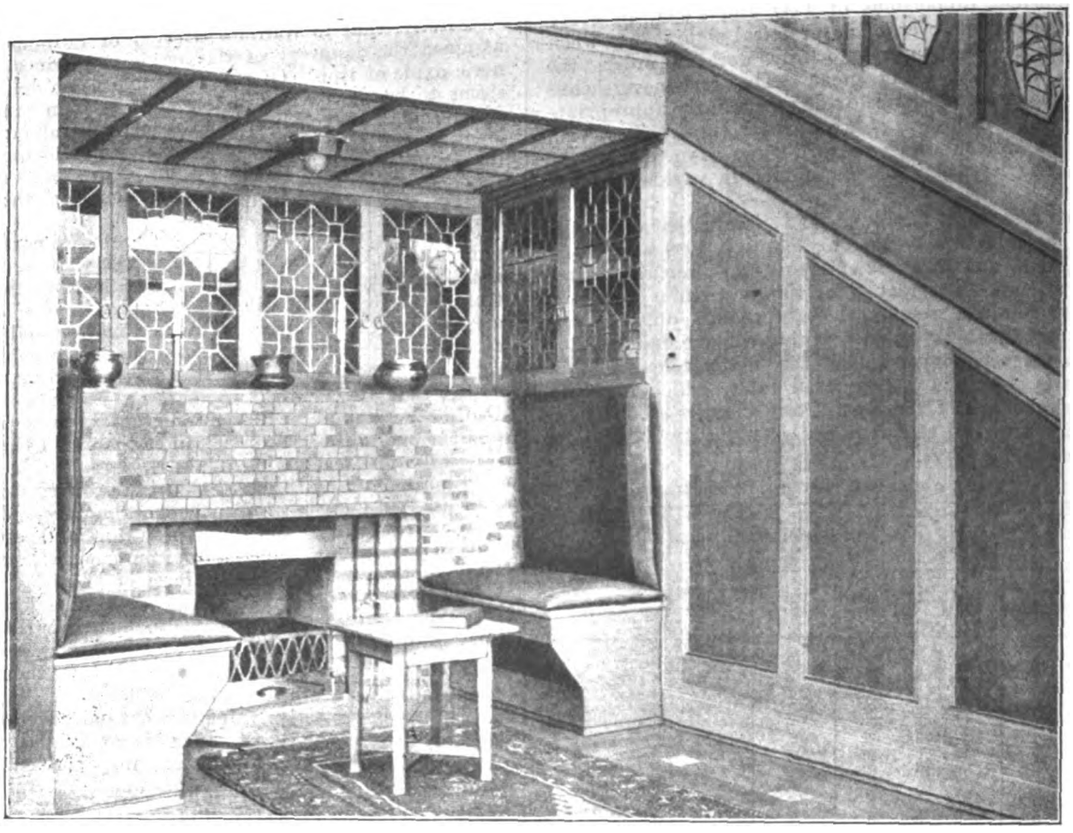
* 0·5 gram of the magnetic oxide is dropped into a nearly boiling hot mixture of 15 cubic centimetres oil of vitriol and 50 cubic centimetres distilled water.

THE BUDGET AND THE BUILDING TRADE.

THE following announcement to the public, being made by over thirty prominent members of the building and allied trades in South London and the suburbs, is being issued through the Budget Protest League as a result of the recent meeting, whereat it was decided to lay before the workmen who are in danger of being thrown out of employment, how seriously their interests are being affected by the Budget, and how still more seriously they are likely to be affected in the future. The announcement shows that over 2,600 out of some 4,900 workers have already been thrown out of employment through the effects of the Budget on the signed firms:—

"We, the undersigned, have been engaged for various periods, in some cases for a large number of years, in developing building estates in various parts of London and the suburbs, and we feel it to be our duty to direct the attention of the public to the grave crisis which threatens the workmen employed in our industry. Our experience is, we believe, typical of that of others in the trade.

"We, in normal times, employed in the aggregrate, directly and indirectly, about 4,944 workmen, clerks, draftsmen, &c., but since the end of May last, owing to the Budget proposals, a considerable reduction has been made, which, in the near future, will be added to.



"It should be remembered that our position may be taken as being that of a vast majority of those who are similarly employed, and since the Budget proposals have been placed before the public no one of us has taken up any land for building purposes. The reason for this is that while we, as traders, are as desirous as ever we were to do business, we are unable to entertain proposals which could result in nothing but a serious loss.

"The increment duty of 20 per cent. and the 100 per cent. increase in stamp duties are, perhaps, the direct causes of the paralysis of our industry and the demoralisation of those who have been accustomed to invest their money in building. Beyond this the little man who buys a single house, frequently paying for it in instalments, will no longer dream of investing his savings, or committing himself financially, by dealing in house property.

"The actual result is that with an immediately diminishing number of workers we are merely completing existing contracts, and seeing that not one of us has bought a single estate since the Budget was introduced the outlook for the winter months, so far as the worker is concerned, is grave beyond any possibility of exaggeration. Meanwhile the average number of men we have employed up to May last number 4,944 and the number now is 2,309.

(From *Dekorative Kunst.*)

"Our workers themselves are realising the position, and they will not be the only ones who will be thrown out of work. Draftsmen, accountants, correspondents, and office staff are in many cases greatly reduced now, but in the course of the next few weeks the majority will have to go.

"We desire to make our position perfectly clear. We are anxious to continue business, we are wishful of finding further work for our men, some of whom have been with us many years, but this is impossible, and we give this warning of the general collapse in the building trade in the hope that something may yet be done to avert what cannot but prove to be a terrible industrial calamity."

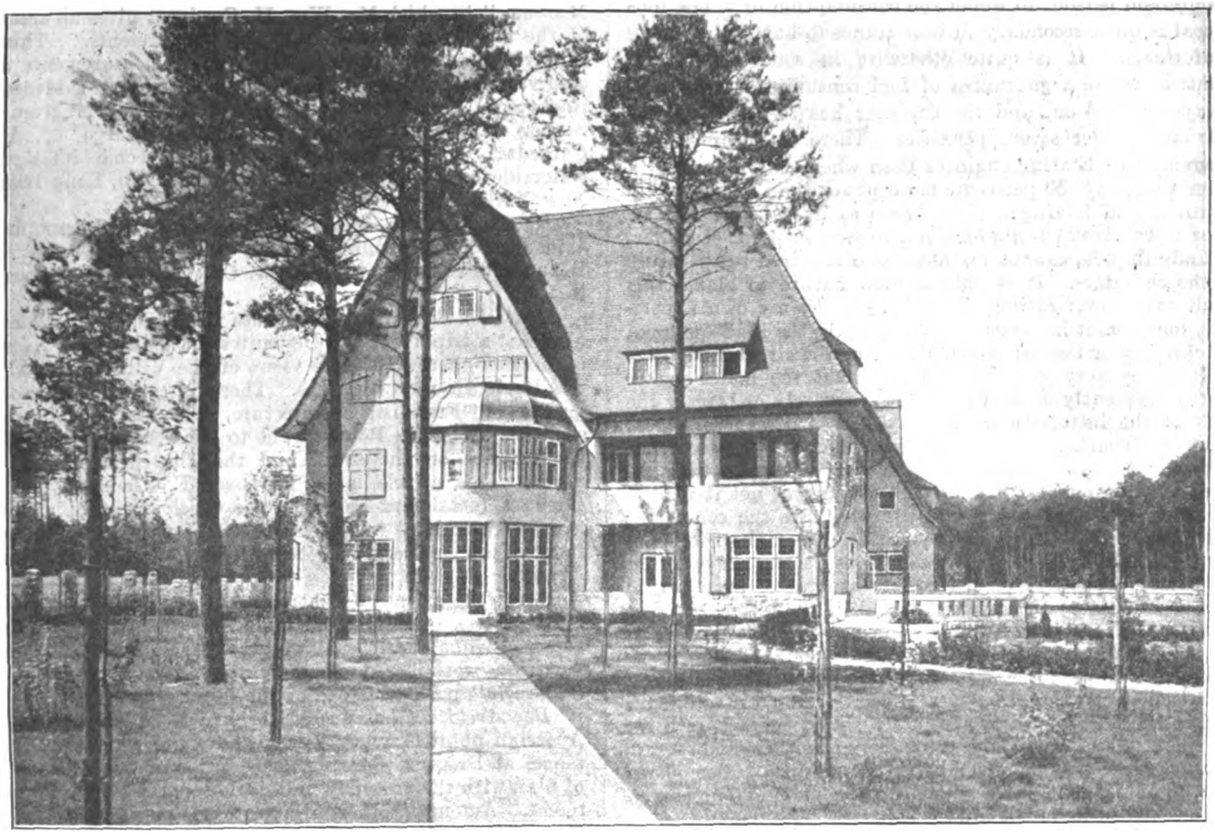
THE RATING AND TESTING OF BOILERS FOR HEATING INSTALLATIONS.*

A GOOD deal of thought has lately been bestowed on the question of standard ratings for low pressure heating boilers, and it has occurred to me that a few observations on the rating, some suggestions as to methods of testing boilers and the scientific considerations involved in this process might provoke some useful discussion.

A committee has been appointed by the Council of this Institution to report to the Institution on the steps which it is desirable to take, and the tests to make in order, if possible, to standardise the rating of boilers. The matter has also been engaging the attention of the American Society.

Now it behoves us to be very careful to inquire in what way such a report can be made most useful to heating engineers, and precisely what it is we wish to accomplish.



The primary object of the heating engineer is to satisfy his client, to put in a good job which will work well, and to get his money and make what little profit there is to be made out of heating with as little fuss as possible, and if the work of this committee does not help him to do this we might as well spare our time for something more useful.

Before, however, proceeding to the consideration of the purely technical considerations involved, it will be advisable to take a rapid review of some very practical questions—that is, to inquire, firstly, what the requirements are for a heating boiler from the point of view of the persons chiefly interested, viz. the client, the caretaker and the heating engineer, and how far experimental results which can possibly be obtained by any process of testing may be utilised to further the objects which we all have in view, viz. the improvement of the appliances used by the heating engineer so as to satisfy all reasonable requirements of the customer? Secondly, the facilitating of the acquirement of exact information as to the performances of these appliances by codifying information experimentally obtained from them in such a way that the ordinary busy heating engineer can be sure of getting pretty well what he wants without making the expensive and humiliating mistakes to which the absence of this exact information not infrequently leads.

* Abstract of a paper by A. H. Barker, read before the Institution of Heating and Ventilating Engineers at Manchester

MODERN EUROPEAN ARCHITECTURE.
GERMANY.

A COUNTRY HOUSE AT ZEHLENDORF-WEST.
HERMANN MUTHESIUS, Architect.
From *Dekorative Kunst.*

Clients.—The general attitude of an ordinary client who puts in a heating installation in his own house, or in a public building, towards the installation is very simple. He wants to be kept warm without feeling stuffy, and he cares not at all how it is done, nor what the temperature is, so long as he feels comfortable, and provided he is not worried by complaints from the caretaker. Also he does not want the installation to be expensive in fuel, although generally he has the vaguest possible idea of what fuel it ought to burn, and does not wish it to take up much of the caretaker's time. That is to say his ideal boiler is one which has a good big fire-box which can be filled up with fuel, and which can then be left to burn itself out. Further, he does not want to be faced with heavy repair bills; in fact, he wants the boiler to be such that it never comes under his notice at all, either by breakdown, noise, smell, coldness of his radiators, and as little as possible in the shape of fuel and repairs. A client or customer never touches a boiler or a shovel with his own hands. He generally obtains his opinion of the boiler, firstly, from what his caretaker tells him about it; secondly, what it costs him in fuel and repairs; and thirdly, how much of the caretaker's time it occupies. That is to say, a boiler which is found unsatisfactory is often or generally condemned by the client on account of matters which have very little to do with the efficiency of the boiler itself. If, for instance, the boiler is fixed below his drawing-room, and the dust and noise of the stoke-hole cause annoyance, or if the chimney does not draw properly so that smoke finds its way into the rooms, or if the boiler is given more work than it can do, so that the radiators are not hot enough; if the fuel is wrong or the stoking bad and the attention indifferent, if the attendant cracks a section with the fire tool, or burns the fire bars by allowing ashes to accumulate, or if the fittings break off, or if he has to shut down several times to repair a leak, or if the installation is apt to boil over on slight provocation, the client is very apt to lay any or all of these defects to the charge of the boiler. If that boiler A were changed at any time for another and perhaps inferior boiler B, and at the same time the attendant were changed for a better one, it might happen that the client would get better results, and form the opinion that boiler B was a better boiler than A.

The Attendant.—The attendant forms his opinion of a boiler almost entirely from the amount of personal trouble it gives him. If it is easy to clinker and easy to clean and to stoke, and strongly made, and is well above its work, and the circulations are well arranged so that the radiators heat evenly, and he does not get into trouble by reason of some rooms being too hot and others too cold, and, above all, if he can fill it up with fuel and leave it alone for many hours, he is very apt to conclude and convince his employer that the boiler is good, even though it is frightfully extravagant in fuel and repairs.

It is evident then that no reliable indication of the excellence of a boiler can be obtained from the opinion that clients form of it. I have known clients to have a very high opinion of a boiler that I knew was extremely bad in every way in which a boiler can be bad.

I often think that a client's opinion of a boiler is formed more from the performance of the chimney and the good design of the circulations than from the qualities of the boiler itself.

The Heating Engineer.—The heating engineer's opinion is often based on grounds almost equally unscientific. He generally favours the cheapest boiler which will work up to its catalogued power without causing him trouble after it is put in, and which is destitute of features against which he has a theoretical prejudice.

A boiler which develops leaks or cracks (it may be from inferior nipples or other causes, or from being badly installed), or a boiler of light construction, of which the hinges are apt to get rusted away, or in which the doors warp and do not fit, or a boiler which gives rise to any complaint of any sort from the client whether well or ill-founded, but which results in an expensive journey to inspect it, is one which the heating engineer does not favour.

In this country at any rate the question of fuel consumption is a secondary matter as far as the heating engineer is concerned. He is not generally asked for a guarantee of fuel consumption, and if he is (if a wise man), he declines to give it on the ground that it depends on the efficiency of the stoking, or on our ever-changeable climate, which makes a satisfactory prolonged test impossible, and on countless other matters. We all know that the total fuel burnt in a winter

Digitized by Google

may vary 50 per cent. or 100 per cent., according to the mildness or otherwise of the winter, and that in this country the man who has his house warmed by an apparatus is generally a well-to-do person, to whom the consumption of a few tons of coal is quite secondary in importance to having his house comfortable. It is quite otherwise in some continental countries where a guarantee of fuel consumption is almost always insisted on, and the engineer has to carry out the guarantee under severe penalties. There is nothing more annoying to a heating engineer than when, having put in a boiler with, say, 30 per cent. more power than is nominally required, and having perhaps done so at his own cost in order to be sure of being on the safe side in point of power, he finds that he cannot maintain the required temperature in the radiators. It is only human nature to blame this result to the over-rating of the boiler. In my own experience, however, it has been more frequently the inadequacy of the chimney or the bad arrangement of the circulations.

It is my very strong impression that the boiler maker is very frequently blamed for what is entirely or largely the fault of the installation. At any rate, whether this is so or not, the heating engineer is at present in the position that he does not know where he is. He does not know when he takes a boiler out of a maker's list whether or not it will do the work it is supposed to do, nor what are the conditions which will enable it to do the work. The maker does not generally tell him on what basis it is rated, nor whether the catalogue powers of the boilers are taken from actual tests or from mere measurements, and, if the latter, on what basis the rating is calculated, nor how the measurements are made, what parts of the boiler are calculated, how much is in contact with the fire, and how much receives direct radiation from the fire, how much is flue or secondary surface, nor how much is absolutely out of contact with the hot gases altogether. The consequence is that in order to be on the safe side he is compelled to put in a boiler 30 per cent. to 50 per cent. more powerful than should be necessary, and even then he is not always safe.

The Boiler Maker.—It is easy to understand the maker's attitude. He does not wish to disclose his method of rating for fear of his rivals, or for fear his competitors will "go one better." It is quite certain that makers will not consent, in the absence of some definite understanding on the subject, to rate their boilers at less than the maximum which they think obtainable. The question therefore arises how far it is possible or desirable to induce boiler makers to consent to a uniform system of rating, on the basis of actual heating surface.

It is obvious that it will be very difficult. Some boiler makers uphold a claim that their particular arrangement of heating surface ensures better transmission and more efficient utilisation of the heat generated in the furnace than the arrangement of their competitors, and they would not consent to be rated on the same basis as a competitor whose design they consider inferior. Also, if a maker has been to considerable expense in making tests and secured certain experimental results from his boilers, he will not consent to rate them at a lower figure merely because a committee of this Institution has decreed that a lower rating is desirable. Again, if a manufacturer has been rating his boilers according to a tradition of his firm, or according to Hood's formula or some similar basis, to alter his rating makes an apparent increase in his catalogue price, which he may think is bad for his business.

Roughly speaking, what heating engineers would probably wish to get from this committee is something of this kind. They wish it to examine, measure or test, either themselves or by proxy, the existing boilers now on the market, and inform them whether or not they are fairly rated, and, if not, what, in their opinion, the rating should be for each boiler of each maker, or perhaps to obtain an undertaking from the maker that he will give the rating according to a standard, presumably to be agreed upon in accordance with the results of certain experiments to be initiated or recommended by your committee.

The broad result is to be that after it is done the heating engineer is to be certain that if his job is, say, 2,000 square feet, then if he puts in a boiler rated on the standard basis as 2,000 square feet, the boiler will actually heat that 2,000 square feet up to the specified temperature. A standard rating is of no use whatever unless it can be absolutely relied on, so that an engineer who puts in a boiler of the proper calculated size, if it will not do its proper duty, may know at any rate that this is not the fault of the boiler.

(To be concluded.)

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *American Architect* contains a further article on "The Architectural Exhibition at the Brooklyn Museum," in which Mr. Wm. H. Goodyear gives an account of the origin of the research that it represents. This is chiefly concerned with Mr. Goodyear's measurements and observations at Pisa, as to which confirmatory evidence of intentional departure from the normal lines is given by Signor Annibale Messini, architect-in-charge of Pisa Cathedral. Illustrations are given of some interesting waterside houses at "Bayberry Point," Islip, Long Island, New York.

La Construction Moderne gives us a typical example of a modern French country house, "Les Quatre Vents," at Beaumont-sur-Oise, of which M. Ch. Langlois is the architect.

Deutsche Bauzeitung continues the account of Professor Manchot's trip from the Dolomites to Venice, and gives in connection therewith some views of the Villa Maser, which the Professor now describes. There is commenced also an article on Frankish architecture, the district of which stretches from the Böhmerwald to the Rhine, and touches the Danube on the south and the Thüringerwald on the north. This article is by Professor F. Ehemann, and in the first instalment he traces the development of architecture in Frankland to the year 1190, illustrating with views from Wurzburg and the monasteries of Bronnbach and Ebrach.

Architekten und Baumeister Zeitung illustrates an extensive block of residential and office premises in Dapontegasse, Vienna, which is an excellent example of modern Austrian work based on the national development of the "Barock" period instead of the latest "new art."

Der Architekt has an article on village schools from an Austrian point of view, as an example of which is shown a school at Bregenz, showing an adoption of the corridor type of plan with the assembly hall quite separated from the class rooms. Amongst other illustrations are a new "Kuranstalt" at Semmering, a suburban house in Vienna, and some views of old work.

The *Engineering Record* has an article giving the results of a series of tests of the bond between steel and concrete made in the laboratory of the Civil Engineering Department of the University of Pennsylvania by and under the direction of H. C. Berry, assistant professor of materials of construction. A valuable article on the design of retaining walls gives the main features of a report by the committee on masonry of the American Railway Engineering and Maintenance of Way Association. Of architectural interest is an account of the construction of the Metropolitan Life building at San Francisco, a building 80 feet by 80 feet and 54½ feet high above ground, in which reinforced concrete is cased with terra-cotta and faience.

GENERAL.

St. Bartholomew the Great, West Smithfield, will be shown and its history explained on Saturdays, October 9 and 16, at 3 P.M. The crypt, cloisters and other portions of the church will be thrown open free of all charge, but a collection will be made for the debt on the restoration.

The Local Government Board have declined to alter their refusal to an application made by the Southampton authorities for a loan of 700*l.* for the purchase of a collection of paintings showing local subjects.

The Lincoln Guardians on Tuesday resolved to employ an architect to prepare plans for a receiving home to be erected on a site just purchased at the corner of Long Leys Road and Mill Road.

The Lancashire Education Committee propose to expend 1,000*l.* on a temporary increase of the county architect's staff to enable him to cope with the higher education scheme. The extension or erection of twenty secondary and technical schools is contemplated.

A Movement of a serious nature has been reported in the north-west pier of the tower of the Abbey Church at Hexham, and examination revealed rather an alarming state of affairs. The clustered pillars forming the east side of the pier in the transepts were found to be considerably out of the perpendicular. It is understood that a report will be presented to the Abbey restoration committee.

Wedham Church, Essex, which has been undergoing extensive restoration, at a total cost of 2,500*l.*, under the superintendence of Mr. T. G. Jackson, R.A., was re-opened on Wednesday.

FORTHCOMING EVENTS.

Friday, October 8.

Architectural Association: Annual General Meeting. President's Address and distribution of prizes.

Saturday, October 9.

Institution of County and Municipal Engineers: Home District Meeting at Winchester.

Northern Architectural Association Meeting at Newcastle: Visit to Scotswood Council Schools (Messrs. Fenwicke, Watson & Curry, architects), and Denton Hall (1622).

Monday, October 11.

Bristol Society of Architects: A Lecture on "Town Planning" at the Fine Arts Academy, Clifton, by Mr. Raymond Unwin.

Tuesday, October 12.

University Extension Guild: A Lecture at the British Museum on "Egyptian Architecture," by Mr. Banister Fletcher, F.R.I.B.A.

Wednesday, October 13.

Manchester Society of Architects: First Sessional Meeting. Presidential Address by Mr. P. S. Worthington, M.A., F.R.I.B.A.

Association of Engineers-in-Charge: Presidential Address by Professor Henry Adams, M.I.C.E., &c., at St. Bride's Institute.

Thursday, October 14.

Society of Architects: Twenty-fifth Annual General Meeting.

Institute of Metals: Autumn Meeting in Manchester, Oct. 14 and 15.

TEXTURE.

THERE are few points in which the architecture of the present day is more remarkable than in the development of texture, and the realisation of what a powerful element in expression lies in the hands of an artist who studies carefully the effect of the variations of texture by which the plain wall may be made as integral a portion of the architect's design as grouping and proportion, moulding and carving, arch and pillar. We will not go so far as to say that texture of wall surface is of primary importance, or even of equal importance with the other elements of architectural design; but, in a perfect building, texture should bear the impress of the artist's handling, and aid in the production of a complete entity, harmonious in all respects.

No doubt in every building accidental play of light and shade, accidental effects of weather and time, affect the ultimate appearance, and the generally greater charm of an old building over a new one is largely due to accidental modifications of the original surface and colouring.

This, however, is not sufficient justification for attempting, as has been done in the past, to eliminate all effects of texture by the production of as nearly as possible uniform surface with the help of Bath stone or Fareham brick, of paint or whitewash or stucco, so as to leave everything clear for accidental modification.

Many means there are for obtaining texture, the play of light and shade, in wall surfaces. The present rage for rough-cast is one of the symptoms of the desire for texture, and this material has not attained its present almost overwhelming popularity entirely from the practical point that it is a cheap way of making thin walls weather-proof. The value of weather-worn old bricks and tiles has been recognised for many years by genuine artistic architects who have felt impelled to depart from the monotonous effect of Fareham red bricks or Cowley stocks, admirable as these are in their own particular direction.

Though not by any means a pioneer, there are few living architects probably who have made more attempts and experiments in texture than Mr. Edwin L. Lutyens, who has been fortunate in finding clients to allow him to experiment with many varied treatments. Chalk, stone, tile, and many specially manufactured varieties of brick have all been employed by this architect, either singly or in varied combinations, to an extent that has perhaps seemed mere fad, but is rather a keen recognition of the infinite amplitude of the effects obtainable in texture by the employment of suitable material.

Part of the effect that material plays in the production of texture is due to variation of colour as well as of form, of the value of varied tones rather than of related or opposed tinctures. Thus the question of texture, though strictly and correctly applied to play of light and shade only, is scarcely separable from the question of colour.

Amongst our illustrations this week are shown two remarkable examples of new buildings in London in which considerations of texture in its widest aspect of surface treatment have been allowed full play, the buildings for two of our insurance companies, the Royal and the Norwich Union, that occupy the prominent positions on opposite corner sites at the junction of St. James's Street and Piccadilly.

In the Royal Insurance building, designed by Mr. John Belcher, R.A., we have an example of the use as a building stone of Pentelikon marble; in the Norwich Union premises, of which Messrs. Ernest Runtz & Ford are the architects, we find Pentelikon marble on a base of jasper, a bold and striking innovation.

Pentelikon marble has only of late years become a possible building stone for British architects by the redevelopment of the marble quarries from which the ancient Greeks derived some of their best material. It possesses a peculiar texture of its own, unapproached by any other marble, and hence quite distinctive. The quality supplied for buildings is not, as is sometimes erroneously supposed, a pure white marble, but contains a subtle tint of variable tone and a certain play of colour that seems to us to become emphasised by atmospheric influences on veins of abnormal composition. These are the more pronounced in the Royal Insurance building, where the material has been longer in position. It might be questioned whether the development of vein markings by the atmosphere does not portend ultimate decay, and the use of Pentelikon marble as a building stone suitable or otherwise for London will very largely depend on the results open to all observers of its employment in these two prominent buildings. The use of a building stone containing a large proportion of calcium carbonate in London or any other large town whose atmosphere is highly charged with the products of coal combustion is, of course, an experiment, and we shall all watch with interest and close attention the use of Pentelikon marble on the same plane, as regards durability, that is occupied by Portland stone. A beautiful material of charming texture Pentelikon must be admitted to be; whether it is also durable is a question time alone will answer.

In the Norwich Union building Messrs. Ernest Runtz & Ford have made a still bolder experiment by the employment, in a building of so great importance and in so prominent a position, of a hitherto practically

Digitized by Google

unknown material, Welsh jasper. The architects can scarcely, however, be charged with undue confidence when we know that jasper contains 93.57 per cent. of pure silica. There is a probability, therefore, of its extreme durability. Of the beauty of the new material there can be no question. With a remarkable range of colour and the appearance as regards texture of a fine marble it at once takes high position as a decorative building material. Distinctly different in composition and structure from a true marble it is clearly far superior in strength and in probable durability. The quarries in North Wales from which jasper is obtained yield a great variety of beautiful stone. That used in the Norwich Union building is known as heliotrope, but besides this there are produced green, buff, yellow, and deep maroon red. Thus we have now at our command a material equal to marble in colour, in polish, in texture, but of certainly vastly superior durability and employable for external work where one would not dare to use any ordinary or true marble of equal beauty in appearance.

COMPETITION FOR TECHNICAL AND SECONDARY SCHOOL AT WORKINGTON.

THE particulars for this competition are not altogether satisfactory, for in regard to the selection of the best design it is stated:—"It is the intention of the committee to entrust the work to the author of the design selected as the best, subject to the approval of the plans by the Board of Education, but the committee do not bind themselves to accept any of the plans submitted, and they reserve the right to alter or adapt the accepted plans in any way they consider necessary. The committee also reserve the right to call in expert assistance in the judging of the plans sent in." "No premium will be given."

The school is to be for 300 pupils of both sexes, and is to combine, to some extent, the functions of a secondary day school with those of a technical institute. There will be required chemical and physical laboratories, steam and applied mechanics laboratory, metal workshop and metallurgical room, woodwork room, art room, cookery room, laundry room, dining room for sixty, besides twelve class rooms, assembly hall, and other usual adjuncts of a secondary school. Provision has also to be made for evening classes for adults.

No limit of cost is stated, but an estimate based on cubing is to be sent in by each competitor. The drawings required are block plan to 20 feet scale, plan of each floor, at least two sections and four elevations to one-eighth scale, and the drawings have to be sent in not later than November 30.

The site comprises three acres, with a frontage of 250 feet to the north-west, and is of irregular trapezium shape and has very uneven variations of level, the difference between the highest and lowest points on the site being about 14 feet and the fall, on something like a hanging level, is about one in twenty. No sewers are shown on the block plan, nor any particulars of water, gas, or electric current supply, or of the nature of the soil.

"The curriculum will necessitate to a considerable extent the separate instruction of boys and girls," but no figures are given of the relative proportion of the sexes to be expected in this instance. Thus there is a good deal of additional information needed by competitors, the obtaining of which will still further reduce the limited time for preparing drawings.

NOTES AND COMMENTS.

THE annual exhibition of the Royal Photographic Society of Great Britain, being as it is the evidence of what is possible in the most able hands of the making of pictures by the aid of photography, is not the place in which we may expect to find a collection of records of architectural work, such as most of the photographs taken by architects are likely to be. But for examples of architecture as an element of beauty in pictorial design the exhibition is quite well worth visiting, if only for impressing upon architects the part that environment plays in the making or marring of a building as a work of art, or in other words the care that should be taken by every architect in designing a building so that it may fit its environment, quite as much as that it should possess

Digitized by Google

merit of light and shade, of contour and mass. To see how a pictorialist in photography renders a building should be a grand corrective to the architectural designer who is given to laying too much emphasis on detail.

Amongst the pictures in which architecture forms part of the subject is "The Pillars of St. Mark," by John M. Knapp, a charming study of the play of light. Similarly this is the principal theme of the Norman cathedral study, "A Gleam of Sunshine," by S. G. Kimber, F.R.P.S. In "St. James's Street, Lincoln," by Bertram Cox, "St. Nicholas, Amsterdam," by William Davenport, and the striking picture, "Cathedral of St. Ouen," by T. Arnold Bennett, we have instances in which the architecture of the main subject forms a picture with its environment. So, too, with the street and canal "In Amsterdam," by F. J. Mortimer, F.R.P.S., with the new town hall of Belfast showing "In the Grey of the Dawn," by Tom Crabtree, with the tops of the cathedral spires in "A Street in Chartres," by Mrs. M. E. A. Powles. On the other hand, in the Italian mountain town of "Antraigues," by James A. Sinclair, F.R.P.S., and the "Burgtor, Rothenburg O. T," by John H. Gear, F.R.P.S., the architecture is the chief thing. The architectural visitor to the exhibition should not miss seeing the series of twelve old London doorways of the late Renaissance period, classified according to the principles of architectural design, by Walter Plomer Young, F.R.P.S.

Some might suppose or say that it is impossible to teach drawing by means of a book, but Ruskin was evidently not of that opinion when he wrote and published his "Elements of Drawing," and, after all, there is so little a teacher can impart by word of mouth to the embryo draughtsman that that little can as well be put into a book. The ability to draw rests so largely with the person who draws that the essential principles on which drawing is founded can very well be expressed *in print*, and may thus be even more readily grasped than *the spoken word*. Hence the appearance of a little book * which puts clearly before a novice those principles or, as the author calls them, "tricks of the trade" is well worthy of notice, particularly as the essentials of drawing are therein well explained. Both Ruskin and Huxley were agreed upon one point—that everyone can learn to draw, some more readily than others, no doubt, as with every other department of knowledge, but all with benefit to their powers of accurate observation and expression.

Mr. Boddington is justified in the sub-title he has adopted, for there can be no question that with the help of his little manual anyone can acquire the power of drawing "freehand self-taught." The method our author follows is admirable—first, the recognition in anything that is to be drawn of the three simple elements, Position, Proportion, and Construction. The means of embodying these elements are well advised. Then comes the question of Relief, the power of seeing in planes and expressing the three dimensions of all solids on a flat surface of two dimensions. This involves and necessitates the use of shading, the first principles of which are lucidly explained.

Admirable are the principles on which Mr. Boddington lays the greatest stress. The necessity for "seeing big," for accentuating vital points and general characteristics. Simplification and the relegation of minor details to their proper subordinate position. Practice as the panacea for all the evils of inexperience and inefficiency of the novice, and the attainment of the power of observing accurately and recording correctly which constitutes, after all, the whole of draughtsmanship.

* *The Drawing Book; or, Freehand Self Taught.* By P. E. Boddington. (London.: Winsor & Newton. 1s.)

The most interesting item to us in the eighty-seventh report of the Commissioners of His Majesty's Woods, Forests, and Land Revenues, is the account of the works undertaken during the year 1908-09 for the preservation of the structure of Tintern Abbey. The resetting of the eastern arch of the tower has been completed satisfactorily—the covering of the tops of all four walls of the tower and of the springers of the groins has also been done in a thoroughly sound and permanent manner so as to exclude water, and has been so arranged as to be unobjectionable in appearance—the walls and arches themselves from this covering down to the springing of the arches have been repaired and pointed on both sides. The utmost care has been taken to preserve all the old features, and to do nothing further than was absolutely necessary for the preservation of the structure, and it is very gratifying to be able to state that no accident has occurred to any of the workmen, although the whole undertaking was of a very difficult and dangerous character. The necessity of these works lies in the fact that last year 17,914 visitors to Tintern would have been exposed to imminent danger from the fall of the great arch and loose stones on the top of the wall which might have occurred at any moment. There have also been carried out repairs to the walls of the kitchen, the Lay Brothers' quarters, and the Frater, securing the tops with cement and turfing them, and some excavations at the Infirmary.

The position of the Crown as a holder of landed property is shown by the fact that, exclusive of land let for building purposes, foreshores and mineral rights, the Crown property under the charge of the Commissioners of His Majesty's Woods, Forests, and Land Revenues extends to about 319,213 acres, of which about 66,688 acres are under timber and 128,117 acres are unenclosed wastes subject to common rights. The School of Forestry has progressed satisfactorily, and a sixth class of eight students has been admitted. Since the school was started twenty-six students have obtained a full certificate, and sixteen students are now in the school.

Mr. Arthur Crow, District Surveyor for Whitechapel, Spitalfields, Mile End New Town and Tower Liberty, offers his contribution to the solution of the housing problem for London in a pamphlet (reprinted from *The Architects' Law Reports and Review*) entitled "Housing and Town Replanning," advocating the formation of a main artery about ten miles long, in the form of a double avenue with central boulevard running nearly east and west, and traversing the County of London from a point near the iron bridge over the Lea at Canning Town to the Uxbridge and Hounslow Roads, which unite at Shepherd's Bush Green. A branch road at Paddington is also provided leading to the Harrow Road.

Thus the tramway systems of the West Ham and East Ham Corporations in the east are to be linked with those of the Middlesex County Council in the Harrow Road and the London United Tramways at Shepherd's Bush in the west; for it is an essential feature of Mr. Crow's boulevard, which is to be 225 feet wide, of which 75 feet on each side is roadway, that double lines of tramways on the surface are to be run in each roadway, with a service of sub-surface trams for express travelling on one side. The Steine Gardens, Brighton, are used as illustrations of the effect of the boulevard, and the scheme is undoubtedly a fine piece of Haussmannising, but Mr. Crow does not claim that it is commercially sound, nor does he attempt to estimate even approximately the number of million pounds sterling that it would cost, and until this is done who can say whether London can afford it, even granting that the hygienic advantages would be great? Kingsway and Aldwych still represent a huge amount of unproductive capital, the loan interest on which is a millstone round the neck of the London ratepayer; so that for the present, at any rate, Mr. Crow's idea cannot be regarded as otherwise than Utopian.

ARCHITECTURE: ITS TRUE PRINCIPLES.—XX.

By R. Owen Allsop.

Mass Balance.

We must institute some principle of arranging masses in the place of universal equal-sidedness. We should employ "symmetry" in its dictionary sense—the due proportioning of the several parts of a body to each other. This opens up scope for any amount of skill and study in composition. In place of the "art" of the turner and that of the potter, we then have one requiring the most lively and deductive reasoning. We can now easily give an impress of strong and, possibly, unique character to a work. The danger is the loss of unity. Pure, equal-sided symmetry, always assuming or indicating a centre, makes for unity in an automatic manner. In what way can we be best protected against the loss of oneness in asymmetrical composition? We have suggested—and it will probably be accepted by the reader—that parallelism, and rectangular relation, in masses, of itself alone, ensures a mind-appreciated bond, where none may appear to the eye. Extension of axis is plainly a principle—the lady-chapel at one with the nave and choir. That which is closely connected physically is most at one, so that compactness where not injurious to the actual service may be considered a rule. Skilful joining, the avoidance above all of ugly gashes in outline, or senseless breaks and set-backs in the main masses are, or should be, self-evident rules. We see, however, a very frequent ignoring of this rule in the case of acute-angle, main plans, as at the junction of streets, a position that absolutely demands either a prominent corner mass or a bold sweep of lines from the side planes right round the curved, or otherwise arranged, corner.

Anything the direct opposite to the modern rambling architecture as homes, hospitals, and the like, will be correct. It must be remembered that we talk sometimes of a "building," where village or town would be a more suitable term. There can be no grand oneness of effect in a mere assembly of individual units even if they all serve one practical end. The wards, service-block, infirmary and other members of the modern institution, facing about in different ways, at varying angles, cannot be arranged into any harmony except in a negative sense—that no member of the group shall be specially obtrusive. Compactness, then, is a first essential in irregular composition—the accurate, well-defined junction, the all-embracing outline, the management above all of roof masses. Unfortunately steel framings falsify the construction—upset the due relation between plan and mass. It is a frequent saying among architects that you can do anything with steelwork—the real meaning being that if you have a fancy for a heavy load over a gaping void, the steel girder can accommodate you fully. Herein is the worst feature of modern architecture, the want of correlation between plan and mass—a thing that never occurred in days of the architecture we now all admire. Every solid mass that appears in the composition must have its corresponding indication—its cause—on the plan, otherwise the whole affair is a sham, as much so as any built-up theatrical scenery. We must at times fall back upon the law of *the sufficient reason* for explaining why the asymmetrical architectural composition may be as pleasing as the purely symmetrical. We see it and must be satisfied. But to practically design to insure against mere patchwork, loss of unity, ugly breaks and gashes, and inconsistency, we must consider the subject relative to simplicity—*i.e.*, naturalness—doing what we want, if right and required, whether or not done before; and remember also the value of the axis and its plane of symmetry, correlation by definite angle, and the great law of balance of parts. We have seen how mere size of parts must always render that feature which is the greatest in cubical contents dominant of smaller masses. This is in accord with natural law. We have suggested—and the point is quite apparent and equally founded on natural laws or natural tendency of the eye (or of the mental eye as a reflex action) that this question of domination of the greater mass can be completely upset by certain relative placing of features, and, on investigating the cause, concluded that in all cases the wings, either as servants or guardians, must refer to the centre. Hence we can always enhance a part of a composition by flanking it. Therefore, if we have any weakly subordinate mass distant from the natural centre of a design, we can, by arranging it in suitable wings, greatly enhance its importance. This can be done to any extent, and is done, even if unknowingly, every time a composition of three things—it matters little what—are arranged on an elevation. In a similar manner we can generally on this principle bind together an otherwise dissolute portion of a design—by creating a centre to which two parts refer. Unity, we may see brought about—the design "pulled together"—by a pair of turrets. What was a weak mass, may, by the addition of flanks, be given just that extra dignity required, and explain also that unity is intended. So in a larger affair of several towers, these can be disposed, not necessarily to direct attention to themselves, but to lead the axis-seeking eye to some especial point.

The great extent to which this principle of centralising a feature, or the artificial creation of a centre or axis, influences effect in geometrical design is only appreciated if the inquiry and study be made. It is the secret of the effectiveness of alternation. The window between buttresses is by the buttresses enhanced. The alternate design principle of the egg-and-tongue and other like enrichments may be instanced. Here, the small ornament is flanked by the two larger, and the larger by the two smaller; so that on whichever object the eye rests it is sensible of bi-symmetrical design. Each ornament thus is enhanced in value by its adjoining ornament, and the effect is *plus* and irrespective of the principles of contrast and gradation evidenced in the general design of this universally-admired enrichment.

That which is flanked by equal-distant, equal-value wings should be worthy of its position, or should (as in the gable between western towers) mark out a worthy object—the great nave. Two large objects placed as wings to a small one over an insignificant centre of an extensive façade is bad composition. The reason is clear: we are —perforce unwittingly—led to a centre point between the flanks, and feel disgust at the meanness we there discover. Hence, in a plan composed of a long building needing, practically, a tower-like structure at one end, and without any important centre, it would be preferable to have a quite unbalanced façade rather than to create an artificial centre.

In general massing the avoidance of ugly gashes is a great thing. That which differentiates one building from another is a more or less pronounced vertical slot, gap or depression, not of itself beautiful. The object being to render a group—in its multitudinous features—as one mass, this appearance of divisional cut is to be greatly avoided. Especially will broken roof-lines, creating a V-shaped depression, break up and annul any unity of effect. Hence the importance of good roof-lines and the need of study and care in roof junctions. A common eyesore in house building of the "parasitically sublime" order is the odd piece of roof breaking down on to some other ridge-line. This is more especially offensive where the more elevated roof-line is that plainly subordinate to the main roof. The ugly gap in the centre of Antwerp Cathedral must be familiar to all, and matters are not improved by the onion-shaped flèche, both strikingly out of harmony with the beautiful tower. Nothing is more satisfactory than a consistent line of roofs over all main parts, and if this cannot be accomplished, then a secondary tower roof-line, embracing in its turn as much as possible. Consistent roof "pitches," based on the fundamental principle of the true proportion—the similitude of ratios—is a very evident working principle in architectural design. That which gives added effect to the Egyptian pyramids as a group is their apparent (or real) constant ratio of base-line to axis. The effect of unity is enhanced, and this would disappear where the several pyramids not true proportionals. Much can be learnt in the prime essentials of composition from these objects. The varied size makes for oneness *in the group*—contrary to what might be

Digitized by Google

thought by those who have not reasoned as to the matter. Three equal objects, each of equal weight and volume, would have equal value and equal effect, so breaking up the idea into that of individual self-assertiveness. The individual should have his value and not be swamped by the architectural community; but short of this the reference must be to the whole interest. From this consideration, evidenced in all fine widely asymmetrical works of architecture, we arrive at the general conclusion that there must be in a composition much wanting in the symmetry of halves, a greatly dominant object, and a general scale of gradation. The reasoning here must be understood to apply to large works where practical service renders necessary a great number of separate parts. In such a case, supposing general and pronounced (by necessity) asymmetry in the plan, the composition may include one dominant, several subdominant, and many minor plainly subordinate features. This consideration emphasises the value of simplicity—and its *power* and sweet reasonableness. For, naturally, the building, as a practical man-serving construction, has diverse parts of varying uses, and yet, as each in its way is important and necessary, it is but straightforward common sense to let each be shown in a natural, unaffected manner. It is evidently the reverse process to that of packing up a medley of rooms into the form of an ancient temple. A superficial examination of this point might lead to the supposition that the showing (plainly) of relative unimportant and humble parts (instead of "boxing them up" into larger units) would result in incongruity and loss of dignity. Our really progressive domestic architecture shows that this is not the case. Ancient examples confirm the opinion.

In what way then do these last-expressed sentiments agree with the anathematising of patchwork? The essential attribute of true "patched" architecture is the absence of

Fig. 42.

thought in the plan—and, indeed, in everything else. The most irregularly-disposed building must show the effect of the brain mastering the plan, and the group arising therefrom will indicate the skill with which this plan has been made. We have argued that a fine building requires a fine site—sufficient ground, at any rate, and that to compare cramped-site architecture and that on broad areas is to compare a self-reliant man, able to work his arms and legs, to a person wedged into, and wholly dominated by, a crowd.

We have suggested that it is in the asymmetrical design that we have scope for—and see all round evidence of—true character and strong personality. In every building having a dome-capped transept and western towers we shall see some echo, or imagine we see some points corresponding to St. Paul's. If, instead, we have a dome, one large tower and minor turrets, we make for individuality—the scope is greater for variation of type. There is more opportunity for that rearrangement of parts that affords us a chance for new combinations—for what is called "originality" and what is called novelty. Let us, therefore, without trespassing against the fundamental necessity for symmetry of halves, strive to cast off, as a disease, that unwholesome forced bi-symmetrical tendency that destroys our best and noblest instincts and aspirations architectural. Let us well ground ourselves, practise and study the art of grouping with balance, such as the tree, by nature, does for itself, and the artist but humbly imitates.

The true balance of asymmetrical massing cannot be accomplished by the mere elevationist. The effect of all disposition on elevation is upset in perspective. The great interest of all objects, large or small, of geometric form—indeed of any form having length, breadth and depth, is similar to that of a cut diamond—it has new interest from every varying standpoint. How great then is the circumspection required for arranging so that from all points there may be balance and no jarring sense of one-sidedness—leaving the mind with a sense of something wanted—some injustice, even if only to the eye. In nature the fact of passing strangeness is the harmonious balance whereby mountain, forest, tree, sky and cloud, sunshine and shadow at all points leave on our minds an impression of balance—that is a fair distribution of interest about the whole view afforded. It may be questioned if there is such a thing as a discord in inorganic and plant life—excepting such as man drives into its domain.

Can we learn nothing from this applicable to asymmetrical geometrical form arrangement? The sinking of all sham—comprising in that deceptive purpose, trick, mean artifice, "subtlety" and affectation—we see that all that is true and of utility if it has no positive beauty, has no offensive ugliness. We may say that the giraffe's neck is less beautiful than man's neck, or than the swan's neck; but it would require boldness indeed to affirm that it was ugly. The designer then need have little compunction in arranging *any* form irrespective of the exact symmetry of halves, so long as it is the result of right reasoning, the subject of regular and geometric form and impressed with the attributes of grace and beauty according to his lights. The architect need not stop to ask whether such and such an arrangement is good, so long as it is suitable, and if its end is beauty and interest of effect.

This is the great lesson that wide experience and travel bring—a knowledge of the power and legitimateness of infinite variety.

(To be continued.)

HEXHAM ABBEY.

THE Rev. Canon Savage writes as follows in the Hexham Parish Magazine for October:—

All who love our glorious abbey at Hexham will be distressed at the paragraphs which have appeared recently in the press, which, though in no sense official, represents, perhaps not unfairly, a grave and imminent danger to part of the fabric. The matter has the careful consideration of the rector and the wardens, who are fully alive to their serious responsibilities as official custodians of the church; as well as of Mr. Temple Moore, our distinguished, able, conservative, and careful architect, and his representatives. The rector, on the first suspicion of the movement or settlement, informed Mr. Temple Moore, who at once made examination and gave his official report. The rector then repaired to London for further information; and, at the request of the wardens, is seeing the architect in London with a view to taking necessary action in the matter.

It is a simple matter for us who have neither expert knowledge nor opportunity for close examination to give snapshot reasons for the cause. To do so may be a harmless pursuit, but let us remember that we are by no means infallible. Certainly there is a movement, the evil is of long standing, and, as we have said, grave trouble is imminent unless we take action.

The movement most emphatically is not caused by any new work. Mr. Temple Moore assures us of this. He says: "My surveyor could find no trace of any movement or settlement anywhere in the new walls and work generally, and at the several junctions with the ancient work, where one might expect to find a trace of movement in the later work settling down, the making good is quite unbroken as when first made more than a year ago.

Digitized by Google

"Now as to the fracture in the walling forming the jamb of the arched recesses over the archway from the north transept to the new nave aisle. The fracture itself has been visible for years, but certainly it appears to have widened considerably during the last year.

"It is true that the other or outer face of this wall has been restored and made good with some new facing, both above the aisle roof and also below it over the archway, but the wall itself is approximately five feet thick, and this refacing would not disturb it. Also the refacing referred to, and the old facing adjacent to it, have not moved in the slightest degree, as may be seen by examining it from the nave aisle roof.

"Again, neither the new or old work below the foot of the recesses, nor on either side in the tower pier, or the aisle archway jamb, has moved or settled in any way."

Mr. Temple Moore emphasises the necessity of immediate attention, and adds: "The wall above the fracture in question is obviously in a very bad condition, especially towards the top. It looks as though there are some stones in danger of falling."

It is not due to new work. Is it due to the fact that this north transept was roofless? What an opportunity for wind and weather, rain and snow, heat and frost to play havoc! Or again, is it due to this part of the north transept having no foundation which goes down to really solid ground? We fear this may be found to account for much.

We have expended much money in strengthening the abbey fabric from insecure foundation and from crypt to topmost pinnacle according to the urgency of the need. Those who admire the beautiful work of restoring and completing the abbey but little realise the immense amount of unseen reparation which we have carried through to save the venerable church from falling in ruin. The account of Messrs. Thompson, Peterborough, was wholly for repair; and reverent repair looms large in the account of Messrs. Holloway Brothers, Ltd., London.

I never like to hurt people's feelings, but I have abundant evidence to show that for centuries the abbey church has been neglected. Why did the east end fall away and the south transept gable fall out, and the north transept ready to follow suit had we not expended 2,000*l.* on it? Yes, and much more I could say. But we love the abbey, and we must save it and treat the old mother church with love and reverent care. She is the mother church of Northumberland, and the worship of 674 is the worship of 1909, and must be, through us, the worship of 2909. It is our trust, our sacred privilege, our precious legacy.

THE ACTION OF AIR AND STEAM ON PURE IRON.*

THE whole subject of the corrosion of iron is one of great importance, both from a commercial and a purely scientific point of view. The desirability of pursuing further research upon it can therefore be scarcely exaggerated, until the numerous problems connected therewith have met with satisfactory solution.

In a recent communication to our Journal I have dealt fully with the action of air, water and steam upon various forms of iron at temperatures not exceeding 100° C., and mentioned that experiments were in progress with the object of determining their action at higher temperatures. As the results obtained have reached the stage at which they can be safely discussed, it seemed advisable to give them publication at this date.

The iron used in this research was in the form of thin foil, which analysis showed to contain 99.9 per cent. of the pure metal.

Action of Ordinary Air on Iron.

It is well known that when iron is heated in air it soon becomes tarnished, and the particular shade which the iron assumes gives a rough indication of the temperature. In order to compare the action of ordinary, moisture-laden air on pure iron with that of perfectly dry air and of steam, each at varying temperatures, the following experiments were performed:—

A tube, sealed at one end and containing a bright strip of iron foil, was immersed in an oil bath and maintained at 100° C. for five hours. At the end of this time no alteration in the appearance of the iron could be detected. The temperature was now raised to 150° C. for a further period of five hours. Even after this treatment it was almost impossible to decide by mere observation whether or not the surface of the metal was tarnished, for the action was so slight.

A fresh strip was now heated to 220° C. in a similar manner, but in twenty minutes a slight straw tint developed, which became more pronounced as the heating was prolonged.

At higher temperatures the oxidation of the iron was much more rapid, and an almost momentary immersion in a lead bath at 350° C. sufficed to produce a clear blue tint.

Action of Perfectly Dry Air upon Iron.

In view of the fact that H. Brereton Baker has frequently drawn attention to the influence exerted by minute traces of water-vapour on certain reactions, it was interesting to inquire whether or no pure iron would undergo oxidation on exposure to air at different temperatures dried over phosphorus pentoxide. The following results were obtained:—

1. A tube, containing a strip of iron, about 6 millimetres long and 4 millimetres wide, separated from some phosphorus pentoxide by a loose plug of glass wool, was sealed. After the lapse of four months the end containing the iron was immersed in an oil bath at 190° C. for thirty minutes. As the change produced was exceedingly slight, the temperature was raised to 220° C. After the expiration of a second half-hour the iron had assumed a light straw tint.

2. Two tubes similar to the above, one of which had been kept for three months and the other six, were plunged into a bath of molten lead at a temperature of 350° C. In a few moments the iron had assumed a bright blue colour.

We thus see that the entire absence of moisture will not prevent the oxidation of pure iron at temperatures of about 200° C. and upwards. These experiments are therefore being continued in order to include a wider range of observation.

Action of Steam on Iron.

For many years chemists have been familiar with the fact that, when steam is passed over heated iron, hydrogen gas is set free and hammer-scale, or magnetic oxide of iron, remains behind. The equation usually assigned to this reaction is:—

$$3Fe+4H_2O=Fe_3O_4+4H_2.$$

In my previous paper attention has been drawn to the fact that a mixture of pure steam and air may be passed over pure iron at 100° C. without producing any visible effect. The following experiments were therefore undertaken with the object of determining if pure CO_2-free steam has any action upon pure iron at temperatures above 100° C., and if so, at what temperature that action begins:—

Temperature Range, 100° to 250° C.—The apparatus used in these experiments is shown in the figure. The distilling flask A, of 500 cubic centimetres capacity, contained a 2-normal solution of potassium hydroxide, and was immersed in an oil bath, the temperature of which was maintained at

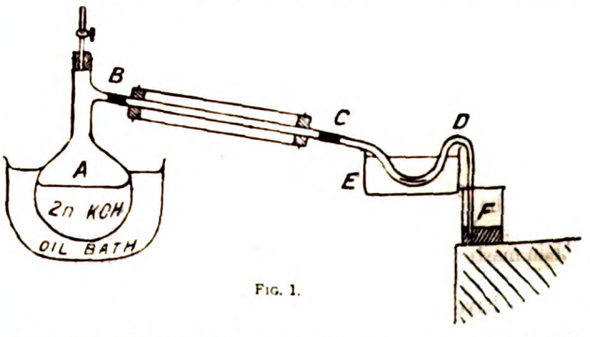

Fig. 1.

approximately 125° C. In order to prevent bumping, the level of the potash solution was kept slightly lower than that of the oil in the bath, and small pieces of capillary tubing, sealed at one end, were dropped into A at the beginning of each experiment. It was found that by adopting these precautions a steady ebullition of the potash could be secured without the manifestation of any tendency to bump. The glass condenser BC was, in the later experiments, fused on to A and B, and connected with the glass tube CD by means of a short piece of rubber tubing. The free ends of the tubes at C were filed to fit one another, in the manner indicated by Bone and Coward, so as to make a tight joint.

At the beginning of the experiment a strip of iron foil 3 centimetres long was put into CD, together with a few drops of potash solution to remove any adhering carbon dioxide. A was now raised to boiling point, and the steam condensing in BC washed the potash away from CD. When the water escaping from the open end F showed no alkalinity to phenol

* A paper read at the autumn meeting of the Iron and Steel Institute, by J. Newton Friend, Ph.D., M.Sc. (Darlington).

Digitized by Google

phthalein, F was closed with a mercury seal, the condenser BC allowed to run dry, and the oil bath E heated to various temperatures not exceeding 250° C. After half an hour's exposure to the action of the steam at any one temperature the experiment was stopped by cooling A and allowing a solution of potassium hydroxide to be sucked up through F into CD.

In no case was the iron found to be appreciably tarnished.

Temperature range, 300° to 600° C.

1. *In Copper Tubes.*—At first BC and CD were made of copper, whilst the oil in E was replaced by lead, the temperature of which was determined by means of a platinum resistance thermometer enclosed in a silica tube. The india-rubber joint at C was prevented from perishing with the heat by a loose wrapping of filter-paper kept moistened by a slow stream of water. The experiments were carried out in a manner precisely similar to that detailed above, save that before each fresh experiment CD was heated in a current of pure hydrogen gas to reduce any oxide. The following results were obtained:—

Experiment I.—Four strips of foil, from 2 to 3 centimetres long, were heated thirty minutes at 330° C. The strips remained quite bright, but each was attacked locally at about four different places—presumably where they had lain in contact with each other.

Experiment II.—One strip of foil was heated for twenty minutes at 445° C. The metal was decidedly tarnished.

Experiment III.—A strip of foil was heated for thirty minutes at 520° C. The metal was thoroughly attacked.

It would appear from these experiments that pure iron is attacked by pure steam at some temperature intermediate between 330° and 445° C. To arrive at a more accurate determination of the temperature, however, it was necessary to eliminate several possible errors:—

(i) Caustic potash readily effects the oxidation of metallic copper in the presence of air, and the oxide thus produced is rapidly reduced by iron to cuprous oxide at temperatures near 350° C., with the simultaneous formation of iron oxide. It is clear therefore that during the initial stages of the experiment the inside of CD could scarcely fail to become oxidised, with the result that, on heating in the lead bath, the iron became slightly tarnished.

(ii) Although the temperature of the bath could readily be determined, it was always possible that the temperature of the steam inside CD was slightly lower than this. As this is, unfortunately, an unknown factor, a correction could not be applied.

(iii) It is well known that iron, in common with many other metals, possesses the property of absorbing quantities of different gases, such as the oxides of carbon, hydrogen, and nitrogen, and that the gases are evolved when the metal is heated. It will be clear that these gases, even though present in very small quantity, might exert a disturbing effect upon the reaction under consideration.

(iv) The most serious source of error, and one which it was found impossible to obviate entirely, lay in the difficulty experienced in removing every trace of air from A and BC. This was rendered practically impossible, because a number of capillary tubes, sealed at one end, had to be introduced into the potash solution immediately before each experiment in order to prevent bumping. The error thus introduced is, of course, slight. It has already been shown, however, that air attacks iron fairly rapidly at temperatures above 200° C. Consequently it cannot be expected that iron will remain absolutely untarnished after exposure to steam containing traces of air for any lengthened period. Bearing this in mind, however, it will be seen that the experiments described in the sequel, though but approximations to the truth, are not without value.

2. *In Silica Tubes.*—In order to eliminate the first two possible sources of error mentioned above, tubes of transparent silica were employed of internal diameter 0.4 centimetre. The length of that part of CD actually immersed in the bath E was 23 centimetres, and the strips of iron (usually two in number) were placed at the opposite end to that by which the steam entered. The latter had therefore to pass through a considerable length of the heated tube before reaching the iron, and had thus a better opportunity of attaining to the temperature of the bath. Only such iron was used as had been previously heated to redness for ten hours in vacuo, whereby the greater part of its occluded gases would be expelled. To remove the air as completely as possible from A and BC, the potash was kept vigorously boiling for from one to two hours before the experiment was commenced, and the condenser allowed to run dry. The silica tube CD could not be filled with potash solution, however, as in the corresponding experiments with copper tubes, for the iron was rapidly tarnished by the action of the silica when all the alkali had been washed away, and before the passage of steam was commenced. CD was therefore filled with semi-normal ammonium hydroxide solution, which served to expel all the air from the tube. On connecting at C the steam rapidly expelled the ammonia and most of the water, and immersion in the bath, already at the desired temperature, served to vaporise rapidly any remaining liquid. At the end of the experiment bath E was removed, and, after cooling to nearly 100° C., CD was rapidly disconnected and plunged into a trough of dilute potash solution. This served at once to cool the tube and preserve the iron in contact with the silica. The metal was then removed and examined.

The following results were obtained:—

Experiment I.

Temperature of oil bath E . .	292° to 297° C.
Passage of steam	60 minutes.

Result: The metal was very slightly tarnished.

Experiment II.

Temperature of lead bath E . .	330° C.
Passage of steam	60 minutes.

Result: Exactly the same as in Experiment I., save that in addition to the slight tarnishing, one strip had a small dark spot where the second strip had lain across it.

Experiment III.

Temperature of lead bath E . .	360° C.
Passage of steam	60 minutes.

Result: The metal was a dark straw colour.

Experiment IV.

Temperature of lead bath E . .	380° to 390° C.
Passage of steam	60 minutes.

Result: The metal was very much darker and thoroughly attacked.

Similar experiments were also performed for thirty minutes each at 430°, 450°, 470°, 510°, and 550° C.; and for sixty minutes each at 430°, 470°, and 500° C. In every case the metal was found to be thoroughly attacked.

Since the iron was only very slightly tarnished, but to an equal extent, in Experiments I. and II., although the temperature difference was above 30° C., it seems reasonable to conclude that the oxidation was caused by the traces of air in the apparatus, to which reference has already been made. Since these traces of air will remain practically constant in amount for any one apparatus, the increased oxidation observed in Experiment III. at 360° C. may be attributed to the action of the steam. As the temperature is raised to 380° C. and upwards, the corrosion becomes still more marked.

It appears, therefore, that steam begins to decompose in the presence of iron at some temperature intermediate between 330° and 360° C.—say, 350° C. in round numbers. It is highly improbable that any definite temperature could ever be fixed exactly at which the decomposition of steam might be said to begin. For at a certain temperature the amount of decomposition which could take place might be too small for detection in one hour, and yet in the course of several hours, days, or weeks be most pronounced. Furthermore, the physical condition of the iron and of the walls of the tubes through which the steam passes will probably exert a marked influence, for it is well known that gases are very susceptible to changes in this respect.

Another way of determining whether or not iron is attacked by steam at any particular temperature would be to observe if hydrogen gas escaped during the experiment. An apparatus is being devised with this object in view. The advantage is that the effect of traces of air would be negligible, but, owing to the solubility of hydrogen in water, the temperature at which this gas could be detected would be almost certainly above that at which the steam begins to undergo decomposition.

It may be of interest to place on record here the action of molten lead on silica. Repeated immersion of the latter for periods varying from thirty to sixty minutes in length, at temperatures ranging from 330° to 450° C., produced but little effect. On cooling the lead could be readily scraped off, leaving the tube nearly as transparent as before. After the prolonged immersion at 500° to 600° C., extending over several hours, to which the pyrometer tube was exposed, the lead was less readily removed. On scraping thoroughly and immersing in nitric acid for several hours the tube became nearly clear again, though a slight milkiness still persisted. It will thus be seen that transparent silica tubes form an

Digitized by Google

excellent protection for a pyrometer immersed in a lead bath —at any rate when the temperature does not exceed 600° C.

The results detailed above are capable of explanation in two ways:—

(i) We may assume, as is usually done, that the iron itself decomposes the steam at those temperatures at which corrosion takes place.

(ii) The reaction may be regarded as taking place in two stages, comprising, first, the dissociation of the steam; and, secondly, the union of the oxygen thus liberated with the metallic iron.

The former view is not easy to reconcile with the fact that hydrogen gas readily reduces the oxides of iron to the metallic condition—a reaction which is the direct reverse of that under discussion.

On the other hand, the second view explains the above anomaly, and is also in harmony with our knowledge of the dissociation pressures of oxygen in equilibrium with steam and oxide of iron.

Alfred Holt, jun., has recently attempted to determine the lowest temperature at which the dissociation of steam becomes a measurable quantity. He finds that at 775° C. very small volumes of electrolytic gas can be collected—a fact which proves that dissociation must begin at considerably lower temperatures. There can, therefore, be no objection to the assumption that at 350° C. steam is slightly dissociated, although the degree of dissociation may be excessively small. It will be clear that, if the partial pressure of the oxygen is ever so slightly greater than the dissociation pressure of any oxide of iron at the same temperature, oxidation will take place. Now Walden has shown that at temperatures as high as 1350° C. the dissociation pressure of ferroso-ferric oxide, Fe_3O_4, is so small as to elude detection. At lower temperatures it will be presumably smaller still, and may well be of the same order as that of steam at 350° C. The dissociation pressure of ferrous oxide, FeO, is likewise excessively small. So that, whichever oxide is formed, there is nothing in these data to render the theory advocated by the present author untenable, and since it possesses several advantages over the usually accepted theory, the author regards it as being more probably nearer the truth.

If this be granted, we have here a means of calculating the dissociation pressure of the oxide of iron produced by the action of steam on the metal at 350° C., for it will be of the same order as the partial pressure of the oxygen in the steam.

From thermodynamical considerations, Nernst and Wartenberg have arrived at the following equation connecting the dissociation of steam with its absolute temperature—

$$\log \frac{2x^2}{\left(2+\frac{x}{100}\right)\left(1-\frac{x}{100}\right)^2} = K - \frac{25030}{T} + 2{\cdot}4 \log \frac{T}{1000} - 0{\cdot}00016(T-1000)$$

where x represents the percentage dissociation of steam, by volume, and T the absolute temperature. To the constant K the value 11.38 is assigned. By neglecting x, as compared with 100, and dividing throughout by 3, we arrive at the simplified equation—

$$\log x = 3{\cdot}79 - \frac{6343}{T} + 0{\cdot}8 \log \frac{T}{1000} - 0{\cdot}00005(T-1000).$$

At 350° C., therefore, $x = 1.02 \times 10^{-10}$, and the dissociation pressure of the oxide of iron is thus of the order of 1.02×10^{-12} atmospheres, which is, of course, far too minute to admit of direct measurement.

Conclusions.

The results obtained in this research may be briefly summarised as follows:—

1. Pure iron combines with ordinary air and with air dried over phosphorus pentoxide with increasing readiness as the temperature rises. Below 150° C. the oxidation proceeds too slowly to be readily detected.

2. When pure iron is heated in pure steam at temperatures ranging from 350° C. upwards, the metal becomes tarnished.

3. The author concludes that the action of steam on iron takes place in two stages, comprising, first, the dissociation of the steam; and, second, the combination of the dissociated oxygen with the iron, and the consequent liberation of free hydrogen gas.

4. If conclusion 3 is correct, the dissociation pressure of the oxide of iron produced at 350° C. is of the order of 1.02×10^{-12} atmospheres.

In conclusion, the author has pleasure in acknowledging his indebtedness to the research fund committee of the Chemical Society for a grant which has defrayed the greater part of the expense entailed by this work.

ILLUSTRATIONS.

NORWICH UNION CHAMBERS, PICCADILLY, W.—GENERAL VIEW—DETAIL OF DOORWAY.

THE Norwich Union building occupies a commanding position, with frontages to St. James's Street and Piccadilly. The façades on the ground floor are in Welsh Jasper, while Greek Pentelikon marble is used for the first floor and upwards. The roof is in purple Broseley tiles. The sculpture, balconies, gutters, and some other features are of bronze. The street angle is surmounted by a group representing "Justice," "Forethought," and "Thrift," designed and executed by Mr. Herbert Binney. The construction is very substantial, and is fire-resisting throughout, as was explained in our issue of February 12 last. The building has been so planned that the floors can be divided up to meet tenants' requirements. Ample sanitary accommodation is provided on each floor. Among the contractors were:—Fire-resisting construction, Messrs. D. G. Somerville & Co.; lifts, Messrs. Archibald Smith & Stevens; wood-block flooring, The Zeta Wood-Block Floor Co.; and general contractors, Messrs. Patman & Fotheringham, Ltd., Theobald's Road, W.C. The architects are Messrs. Ernest Runtz & Ford.

ROYAL INSURANCE BUILDING, PICCADILLY, W.

THIS building, designed by Mr. John Belcher, R.A., stands on a site similar to, and facing, the Norwich Union building, which is also illustrated this week. Both buildings have frontages to Piccadilly and St. James's Street, and both extensively employ Pentelikon marble, supplied by Marmor, Ltd. The Royal Insurance Co., Ltd., occupy the greater part of the ground and mezzanine floors for their West-end offices. The steel framework is carried up to the roof. The 30 feet retaining wall to the basement and lower ground floor is of concrete, reinforced with indented bars. The building is carried on seven steel stanchions, each supporting from 400 to 600 tons dead weight. The window frames and casements on the ground and mezzanine floors are of bronze, and those above of steel. The Mansard roof is covered with Westmorland slates, with bronze-covered dormers. The sculptured figures recessed at the third floor level are by Mr. Bertram Mackennal. The general contractors were Holloway Bros., Ltd.

WINSFORD AND EAST DENE, MURRAY ROAD, WIMBLEDON.

THESE two houses, standing on frontages of 50 feet each, have recently been completed in Murray Road, Wimbledon Common. The external facings are of purple stocks, with red-brick bands and enrichments in the case of the former, and with red quoins and dressings and tiled enrichments in the latter, having rough wide joints. The roofs are covered with thick handmade sand-faced tiles. The entrance door and pilasters of Winsford are old, and belongd originally to Merton Abbey House, which Nelson used to frequent. The entrance pathways are paved with old flagstones. The accommodation in each case consists, on the ground floor, of dining-room, drawing-room, morning-room, staircase-hall, garden-hall leading to verandah and stone-paved court in the rear, pantry, lavatory, w.c., kitchen, scullery, and offices. As the fronts face N.E., the kitchens and morning-rooms were placed there, leaving the best aspect for the dining-rooms, drawing-rooms, and sitting-halls. On the first floor there are four bedrooms, large dressing-room with fireplace, bath-room, w.c., h.m.c., and linen-closet. The attic floor has three bedrooms, box, and cistern-rooms, &c. Mr. A. Leather, of Wandsworth, was the builder, and Mr. Walter E. Hewitt, A.R.I.B.A., of 22 Buckingham Street, Strand, W.C., was the architect.

ROCK AND ITS CHURCH.

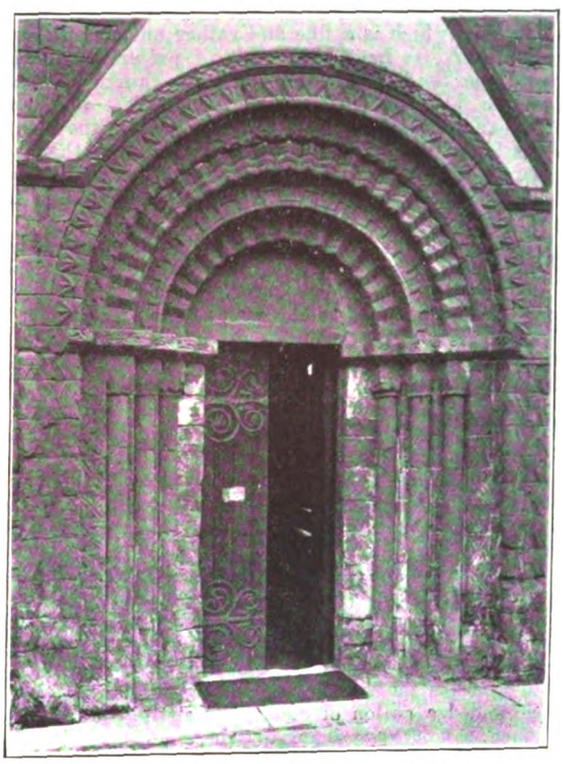
MANY interesting churches and relics of the past are to be seen in ground explored by few, far from the main highways. Amongst these is the church of SS. Peter and Paul, in the village of Rock, Worcestershire.

The parish of Rock, the original name of which is "AK," being the Anglo-Saxon for "oak," possesses an Early Norman

ROCK CHURCH—INTERIOR.

church of particular interest. The registers, which date back to 1547, contain as the first name that of John Borarton, who had a child christened on June 11 of that year. They are complete down to 1642; then there is mutilation, and the next entry is July 5, 1653, after which there is another gap, and they recommence in April 1678, and so continue complete to this date.

It is recorded that in 1510 Judge Coningsby added to the church the south aisle, the chantry of St. Mary and St. George, and the tower. He is also credited with having lengthened the chancel, and with having broken into a great deal of the Norman work. Others have also erased much of the



ROCK CHURCH—NORTH SIDE.

original character of the church. The restoration work which has been carried out during recent years is far from satisfactory. Many of the windows in the nave, chancel and tower have been removed and tracery work placed in the openings which is hardly in keeping with the general character of the church.

One notable feature is the entry at the north door, it being by a descent of three steps. Nash asserts that part of the present church is Saxon, and gives as his reason these three steps down into the church. There is, however, no trace of Saxon stonework to be found to bear out this theory.

The accompanying illustrations show the north door and

NORTH DOOR, ROCK CHURCH.

the interior, the latter showing the chancel arch, and both being striking examples of Norman work.

This church is one of the many in which the chancel is not in a line with the nave. It has been suggested that as

THE FONT, ROCK CHURCH.

the church is dedicated to SS. Peter and Paul this may account for the varied axial alignment. The one part may have been dedicated to St. Peter and the other to St. Paul.

Digitized by Google

The orientation of the chancel being in June and that of the nave in January, would have varied according to the position of the church to the sun, but there are so many churches of single dedication in which variation of axial line exists, that the theory is more plausible than probable.

Another conspicuous detail which still exists is the line of corbels of the Norman roof. The outline of the old waggon-tilt Norman roof over the chancel arch can also be distinguished.

The font, which is a fine and rather unusual example of Norman work, is in a good state of preservation, as will be seen from the illustration. That this church was a silent witness to much strife is proved by the fact that various grooves and marks are still to be found on the stones on the outside of the church, where men sharpened their spears or arrows, either choosing this particular stone because of the hardness, or wishing to sanctify their weapon before departing to battle.

On the south wall of the tower there are marks of bullets caused by the tower being used as a target by the Duke of York's Volunteers at the beginning of the nineteenth century. Evidence is also to be found of the precautions taken to guard against marauders in early times, as in the north doorway there are traces of slots for some sort of a heavy bar to bolt the door.

Standing in the church is a curious old chest, cut out of a solid log of a tree and studded with nails to prevent pilfering. It is evidently a Peter's pence chest, as there are three rough escutcheons where there were old locks, and another where there was a slot to drop the coppers in. The present hinges are Jacobean, but the remains of the old hinges still exist.

In the roadway adjoining the churchyard are to be seen a whipping-post and stocks. The whipping-post has a double lash, one part for a man, and the other for a woman. The stocks have been used, one is informed, in the memory of man. It is also reported that the parish constable who lived opposite the stocks, once placed a man in them and then fetched a gallon of cider, and sitting down beside the prisoner they both got drunk together.

As is the case with all old villages many strange and curious stories are current of the customs that existed in the early days. The following is perhaps the most interesting. It is said that raindrops caught on Ascension Day were carefully bottled, and, receiving the name of Holy Water, were a certain cure for sore eyes. The idea is evidently taken from the disciples gazing at the receding form of their Master on the cloud. It is said there are some old folk still living in the parish who have the same superstitious beliefs.

THE UNION OF ENGINEERING SOCIETIES.*

LAST year when I had the honour of addressing you on an occasion similar to that which calls us together this evening, the Civil and Mechanical Engineers' Society was on the point of completing the first half century of its life as a technical organisation.

At the present moment our Society has advanced a small, yet appreciable, distance into the second half of the century, and, as you may judge from the annual report which was presented by the Council at the concluding meeting of the past session, we commence the new era with unabated strength. Our capacity for usefulness is greater than ever before, our membership exhibits marked increase, and our financial position is thoroughly sound. These facts in themselves would justify the most favourable prognostications of future usefulness. Nevertheless, a definite scheme is now before all of us providing for the extinction of the Society in an individual capacity, a precisely similar proposal having been submitted to the members of the Society of Engineers, which also is enjoying unexampled prosperity. The two projects are virtually one, resulting from the deliberations of the Joint Committee of the two Societies under the chairmanship of Professor Henry Adams, and which foreshadows the incorporation of an entirely new organisation to be entitled the Society of Engineers (Incorporated), and empowered to take over the work and property of the Society of Engineers founded in 1854 and of this Society founded in 1859.

I desire to say emphatically that the incorporated society will not arise from the ashes of two defunct bodies. On the contrary it will come into existence by the voluntary union of two associations full of vitality, drawn together by similarity of aim and by the firm belief that united effort will be to the advantage of all concerned.

Of course, it will be understood that the final decision rests with the members of the two societies. If the general consensus of opinion should be adverse, then for this Society I can say that we are fully prepared to continue alone, looking into the future with absolute confidence. But my hope, and the hope of my colleagues on the Council, is that the scheme of incorporation will be carried through.

Some reference to the subject was made in my address of last year, when I did not feel at liberty to enter into details. On the present occasion, however, there is no reason for reticence, and I gladly avail myself of this appropriate opportunity of making some remarks upon the general bearing of the scheme of incorporation. At the outset I think it only right to express the indebtedness of this Society to our honorary secretary and fellow member, Mr. A. S. E. Ackermann, for the immense amount of laborious work he has performed in preparing for consideration drafts of the rules and by-laws intended to govern the operations of the incorporated Society. I have also great pleasure in bearing witness to the tactful manner in which he has acted as the official intermediary between the two organisations concerned and in directing your attention to the valuable work done by Professor Henry Adams, a past president of both societies, and by Mr. R. H. Willcocks, who has acted as our honorary solicitor for a long period of years.

The memorandum and articles of association embodying the constitution of the new Society, which I may perhaps venture to say is about to be formed, are drafted, like those of the Institution of Mechanical Engineers, the Institution of Electrical Engineers, and other important institutions, in accordance with the provisions of the Companies Acts, the object gained by taking advantage of those statutes being the assured legal status of the association indicated.

In the title "The Society of Engineers (Incorporated)," we have a permanent record of the fact that a new society—neither the unincorporated Society of Engineers nor our own unincorporated Society—is about to be brought into existence.

The objects of the proposed corporation as defined in the Memorandum of Association need no comment, for they are virtually the same as those which have been consistently before the Society of Engineers since December 1857 and the Civil and Mechanical Engineers' Society since May 1859. An important point to be noted, however, is that the incorporated society will possess legal rights never enjoyed by either of the informal associations.

Turning now to the articles of association, I may mention first that four classes of corporate members and one class of non-corporate associates are contemplated, instead of three classes as heretofore. The class of members is retained; existing associates are eligible for election into the new class of associate members, a new class of associates being formed for those not qualified professionally, or by reason of age, for the privileges of corporate membership; the new class of Fellows provides a mark of distinction for members qualified by adequate professional training and experience and by examination, the only exceptions contemplated being those in favour of presidents and past presidents and members of council; the new class of Honorary Fellows will supersede that of honorary members, and involves no change beyond a slight alteration of style.

The only remark I need make concerning these classes is, that the proposed creation of Fellows is one distinctly calculated to benefit the incorporated Society, because it will establish a class of members known to have complied with recognised standards of general education, technical knowledge, and personal experience. As announced in the presidential address delivered by Mr. J. C. Inglis in November 1908, the technical proficiency attached to membership of the Institution of Civil Engineers has induced the War Office and the India Office to entrust the council of that institution with the important function of selecting and recommending candidates for appointment to the reserve of officers for the Royal Engineers and for engineering appointments in the Indian Public Works Department. Communications concerning the recommendation of engineers for public works appointments have also been received by our own Society, and, as I am informed, by the Society of Engineers. The growing recognition of engineering institutions and societies by Government Departments and public authorities is certainly a strong reason for the establishment by the proposed incorporated society of the special class of members qualified by examination as well as by engineering training and experience.

* Presidential address by W. Noble Twelvetrees, M.I.Mech.E., A.M.I.E.E., M.R.S.I., delivered on October 7 before the Civil and Mechanical Engineers' Society.

Digitized by Google

Passing next to the constitution of the council of the incorporated Society, I am pleased to say that owing to the large number of new members elected to the Civil and Mechanical Engineers' Society during the past two years we have become entitled to a very strong representation, comprising four ordinary members of council and two past-presidents—the former chosen by seniority of election to our present Council, and the latter being the two last presidents of this Society. A further satisfactory detail is, that one of the members of our present Council has been nominated by the two councils as one of the vice-presidents.

An additional illustration of the equitable manner in which the interests of this Society have been studied is furnished by the clauses entitling all members and associates of this Society to become corporate members of the incorporated Society without entrance fee, and during the first three years to pay lower annual subscriptions than those stated in the general schedule.

Another point to which the attention of members may be invited is, that in the annual list of members and associates of the incorporated Society the names of the past presidents of the Civil and Mechanical Engineers' Society will be printed in a separate list, together with past presidents of the Society of Engineers and past presidents of the incorporated Society. Moreover, the names of all living past presidents of this Society will be printed in capitals in all lists of members, with a note of the office held after their names, while members and associates of this and the other unincorporated society will be distinguished by a small initial letter printed opposite the date of original election.

These are the chief matters of direct interest to us as a Society, and I think we have ample reason for being satisfied with the terms of unification expressed by the memorandum and articles of association of the Society of Engineers (Incorporated).

By entering into the arrangement proposed we shall give up nothing but our separate existence, which also will happen to the Society of Engineers, and thereafter the members of both associations, as existing to-day, will be jointly the founders of the new corporation, which there is every reason for believing will soon justify its right to be classed among the great institutions representing the engineering profession in this country.

Although in sympathy with the regret doubtless felt by some of our older members that the independent career of this Society will be ended by the adoption of the scheme now awaiting final confirmation, I cannot avoid the conclusion that if carried into effect the union of the two organisations concerned will be an unmixed blessing. It will constitute the first important step towards the alliance of engineering societies having the same objects in view—a consummation whose desirability was urged in my address of last year.

The position of the engineering profession to-day is such that it cannot be fully represented by any one of the existing institutions. The scope of the Institution of Civil Engineers is sufficiently catholic for the inclusion of all engineers possessing the requisite qualifications. In that respect it somewhat resembles the Church of England, whose tenets are broad enough to cover the doctrines of practically all Protestant churches in the United Kingdom. No one in his senses can conceive the possibility of merging other organised bodies of qualified engineers into the premier institution, or of persuading denominational churches to enter the fold of the Church of England. Separate institutions representing one profession and separate churches representing one religion will continue their separate existence, but there is no reason why independent organisations should not enter into bonds of union one with another, for the purpose of furthering the good work conducted by all.

Confining attention to engineering, I take the opportunity of advocating once more the effective co-operation of engineering institutions and societies. It is very easy to suggest ideas of the kind, and very difficult to get them carried out. Such a task is immeasurably beyond the power of any one organisation. It is quite possible, however, for one energetic society to accomplish something in the way of unification on the lines of the affiliation scheme embodied in the by-laws of the Royal Institute of British Architects approved by the Privy Council in February 1889.

In those regulations it is provided that any architectural society outside the metropolis in the United Kingdom, in India, or in any Colony or Dependency of the United Kingdom, may be allied with the Royal Institute. The allied societies preserve their independence of action and secure two important privileges, one being that the president for the time being of every allied society within the United Kingdom has a seat on the Council of the Royal Institute, and the other is, that the Royal Institute contributes each year to every allied society not more than one-fourth of the annual subscription paid to the Royal Institute by each member thereof, who is also a member of the same allied society in respect of and for his subscription thereto, such contributions being withheld in cases where there is duality of membership in allied societies. Of course, there are other necessary safeguards in the by-laws to which I refer, but these do not affect the general character of the scheme.

At the present date the societies allied to the Royal Institute of British Architects are nineteen in number, seventeen being located in the United Kingdom, one in Australia, and one in South Africa. Each allied society is the accredited centre of a district, and the official representative of that district in its relations with the centre of the organisation in London.

The names of the allied societies and the districts they represent are the following:—The Northern Architectural Association (Newcastle-on-Tyne) represents Northumberland and Durham; the Leeds and Yorkshire Architectural Society represents the great part of Yorkshire; the York Architectural Society represents the parliamentary division of York and most of the North Riding of Yorkshire; the Sheffield Society of Architects and Surveyors represents Derbyshire, north Lincolnshire, and part of south Yorkshire; the Manchester Society of Architects represents part of Lancashire, part of Cheshire, Cumberland, and Westmoreland; the Liverpool Architectural Society represents part of Lancashire, part of Cheshire, with the counties of Anglesea, Carnarvon, Denbigh, Flint, Merioneth, and Montgomery, and the Isle of Man; the Nottingham Architectural Society represents Nottinghamshire and part of Lincolnshire; the Birmingham Architectural Society represents Warwickshire, Staffordshire, Shropshire, Herefordshire, and Worcestershire; the Leicester and Leicestershire Society of Architects represents the counties of Leicester and Rutland; the Bristol Society of Architects represents Gloucestershire, Wiltshire, Somersetshire, and Dorset; the Cardiff, South Wales, and Monmouthshire Architects' Society represents the counties of Glamorgan, Brecknock, Radnor, Cardigan, Pembroke, Carmarthen, and Monmouth; the Devon and Exeter Architectural Society represents Devonshire and Cornwall.

The above-mentioned societies, together with the home district of the Royal Institute, cover the whole of England and Wales. As the home district is rather a large one it is proposed to establish a new society to represent the counties of Cambridge, Huntingdon, Norfolk and Suffolk.

Scotland brings into alliance with the Royal Institute the following societies:—The Glasgow Institute of Architects, representing the counties of Dumbarton, Sterling, Renfrew, Lanark, Ayr, Kirkcudbright, Wigtown, Argyll, and the Isles; the Dundee Institute of Architecture, Science and Art represents the counties of Forfar, Perth, Fife, Kinross, and Clackmannan; the Aberdeen Society of Architects represents the counties of Aberdeen, Kincardine, and Inverness, and the North of Scotland; the Edinburgh architectural Association represents the counties of Linlithgow, Edinburgh, Haddington, Berwick, Roxburgh, Dumfries, Selkirk, and Peebles.

In Ireland the Royal Institute of the Architects of Ireland represents the whole of the country. In Australia the Institute of Architects of New South Wales represents the State of the same name, and in Africa the Cape Institute of Architects represents Cape Colony.

From the foregoing particulars it will be seen that the architectural profession is excellently organised, the Royal Institute having established intimate relations with the principal local institutes and societies, which, although not creating a vast association like that of the German Society of Engineers, or the Austrian Society of Engineers and Architects, nevertheless goes a long way towards securing the effective union of the organisations concerned.

The only action of similar character with which I am acquainted is that which brought into existence the Institution of Mining Engineers, a body including the North of England Institute of Mining and Mechanical Engineers, the North Staffordshire Institute of Mining and Mechanical Engineers, the Midland Institute of Mining, Civil and Mechanical Engineers, the South Staffordshire and East Worcestershire Institute of Mining Engineers, and the Mining Institute of Scotland. The constitution leaves independent action to each institute as before, but all papers read are published in one journal and each institute pays a capitation grant to the central body, which, comprising some 3,000 members, is able to deal with matters affecting the in-

Digitized by Google

terests of mining engineers far more authoritatively than a number of isolated institutes each with a small membership roll.

The examples set by the Royal Institute of British Architects and the Institution of Mining Engineers might well be followed by the alliance of the many engineering societies existing in various parts of Great Britain with each other and with a central society in the Metropolis. If the Civil and Mechanical Engineers' Society should decide to abstain from the scheme of union now before the members, the work of unification to which I now allude is one that would deserve serious consideration. But it could be attempted with greater prospects of success by the proposed Society of Engineers (Incorporated).

Assuming the foundation of that organisation, I think there should be no serious difficulty in the way of linking up all unattached provincial associations as societies allied with the Society of Engineers (Incorporated).

At the present time there are probably more than thirty local bodies of the kind, among the more important being the Liverpool Engineering Society, the Manchester Society of Engineers, the Midland Counties' Institute of Engineers, the North-East Coast Institute of Engineers, the Bristol Society of Engineers, the South Wales Institute of Engineers, the Institute of Engineers and Shipbuilders in Scotland. Adding to these the engineering societies attached to universities and colleges, we have ample material for the creation of a combination of several thousands of members, associates, and students. If these various organisations were once allied one with another, and at the same time with the proposed incorporated Society of Engineers, a great step would have been taken towards the consolidation of the engineering profession. The commanding position of a society embodying a large portion of the engineers of Great Britain should facilitate the ultimate alliance of the institutions representing special branches of engineering practice, and lead at last to the organisation of our profession on a scale worthy of the importance which it has justly acquired.

Finally, I take this opportunity of thanking you most sincerely for the high compliment implied by my election for the third year as president of this Society, and of expressing the hope that the scheme jointly prepared by your Council and that of the Society of Engineers may prove to be only the commencement of more extended efforts towards the union of engineering societies and institutions.

FIRE PREVENTION.

AT the City Court, Dr. Waldo concluded an inquiry into the circumstances attending the fire which occurred early on the morning of September 17 at 14 London Wall, E.C., on premises in the occupation of Messrs. Shortt & Kilpin, Ltd., wholesale milliners.

The building was one of six floors, and, according to the evidence adduced at the first hearing, the fire broke out in the lift, in which some warm ashes had been left. There were traces of a second fire having occurred in a cupboard in the showroom, and the inquiry had been adjourned to allow of a further inspection, in order to ascertain whether there was any connection between the two fires.

Miss Elizabeth Laws, employed by the firm, stated that she was positive that everything was safe when she left the building on the night previous to the fire. It was never necessary to strike a match in the showroom, and no one smoked on the premises.

Miss Gertrude Kilpin, managing director of the company, confirmed Miss Laws' evidence, and said that she believed that Mr. Shortt lit his pipe before he left. Until she was told about the warm ashes being found in the lift the fire was inexplicable to her. The value of the stock destroyed was about 700*l*. or 800*l*. Witness first became aware of the fire when she arrived at business in the morning. Many of the articles used in the manufacture of ladies' hats were highly inflammable, some containing celluloid.

Thomas Shortt, of Friern Lane, Friern Barnet, N., a partner and director of the firm, said they would lose several hundreds of pounds by the fire. He stated that some buckles and hatpins used in the business were highly inflammable, being composed of celluloid. The lining material of hats was also highly inflammable. The building was hopelessly damaged by fire, smoke, and water. He could not account for the outbreak.

Mr. C. W. Surrey, district surveyor for the western division of the City of London, said he had made a survey of the burnt premises. Instead of paying him for the work, the L.C.C. owed him the money, and he added that he supposed he would have to sue them in the county court. The Council rarely paid his fees.

The coroner said he had a similar experience when he was appointed coroner for Southwark, and was unable to get any money until he appealed to the Home Office, who, after considerable delay, adjudged him payment at the rate of 6*s*. 8*d*. per inquest, whilst other London coroners received 30*s*. per inquest from the L.C.C.

Mr. Surrey stated that the building was composed of highly inflammable materials, matchboarding entering largely into the construction. He made an investigation to ascertain whether a spark could have run from the lift behind the matchboarding of the showroom cupboard, and came to the conclusion that this had not happened.

As to the origin of the outbreak, Divisional Officer Dyer, London Fire Brigade, said he was satisfied that the fire in the showroom cupboard was a separate outbreak, but it might have originated from a spark.

Colonel Fox was of opinion that the fire in the showroom cupboard was distinct from the fire in the lift. The same building was destroyed by fire on November 17, 1901, when other tenants were in possession.

In summing up, the coroner said he frequently found that fires in the City of London were due to gross negligence, and the law might, if strengthened, prevent a lot of unnecessary fires. At present it was no offence to throw down a light. Culpable carelessness—short of intentional firing or arson—should be made a punishable offence. He would report any recommendation by the jury to the Home Office and to the Lord Mayor.

Answering questions put by the coroner, the jury found that the fire started in the lift, that there was no evidence to show how the cupboard fire occurred, and that there was absolutely no evidence of incendiarism.

THE RATING AND TESTING OF BOILERS FOR HEATING INSTALLATIONS.*

(*Continued from last week.*)

Possibilities of Accurately Rating Boilers.—The crucial question is this, Is it possible to rate boilers according to a standard which is scientific, practical and accurate? Is it possible by codifying, tabulating and analysing the results of a large number of careful experiments to arrive at such a formula as will give what may be called a figure of merit of any boiler, so that one would be enabled to say of two boilers of different types, from measurements alone, that the power of the one is to the power of the other, in the same situation and provided with the same fuel, as 1 is to 1.34, suppose? Will the two boilers always bear the same ratio to one another if they are fixed in identical situations? Has 1 square foot of direct heating surface—i.e. in contact with flame—always the same power, however it is disposed with regard to the hot gases passing over it? If it has not, then unless one can calculate as many factors as there are different possible dispositions of heating surface, it is impossible by any conceivable system of calculation from the measurements only to arrive at a close approximation of the power of the boiler, and the actual heating surface, however accurately given, is not an accurate indication of the power of the boiler.

Now it is quite certain that different portions of the direct fire surface of the same boiler do in fact possess widely different values as heating surface. Surfaces over which the water is moving rapidly will take up a great deal more heat from the furnace than those portions of the surface over which the flow of water is slow. Similarly those portions of the fire surface on which the hot gases impinge directly will take up from the hot gases a great deal more heat than those portions over which the gases move tangentially and slowly. If, then, you compare two equal small surfaces of direct fire surface in the same boiler, over one of which the water and the hot gases are both moving rapidly, the flow of gas being direct impingement, that portion of surface must be not only more, but very much more, efficient than an equal surface of the same firebox over which the movement of water and hot gas is tangential and slow. This being so, it appears to be proved that it is quite possible to have two boilers of different types, each having, let us say, 30 square feet of direct fire surface, and 60 square feet of indirect, and say 70 square feet of secondary surface, whose heating powers may be widely different. If this is so, then mere measurements of the

* Abstract of a paper by A. H. Barker, read before the Institution of Heating and Ventilating Engineers at Manchester.

Digitized by Google

surface, however carefully made, are no reliable indication of the power of a boiler, and one maker's tests will be of very little use to any other maker of a different type of boiler.

My own opinion is that the only method of ascertaining accurately the power of any boiler is to make a prolonged and careful test on a boiler of similar design, and I do not think that measurements of different types of boilers can be expected to give more than a very rough indication of their relative powers. It is practicable so to test boilers as to obtain a result which can be reproduced at any future time, and no test is of any value unless it is made in such a way that the same result can be reproduced at any future time if required. I believe, too, that if tests are made of several boilers of a series, all being of similar design, a formula can be evolved which will give a very close approximation to the actual power of any boiler of that design if tested in the same way as the other, and this in my view represents the limit of possibility in evolving formulæ for boiler rating, and if anything more than this is attempted—that is, if an attempt is made to rate boilers of different design from the same formulæ—it will, I believe, be a failure.

There can be no doubt that the actual power of any boiler, that is the number of B.T.U. which can be obtained from it, varies very much according to circumstances. It is often possible by altering the conditions under which a boiler is working even to double the maximum power which can be obtained from it.

It appears, therefore, manifest at first sight that to lay down any hard and fast rule as to the power of a boiler is absurd, except as a rough approximation for ordinary conditions. I have frequently contended at these meetings for a more general recognition of the principle that any hard and fast statement of power of any apparatus is inaccurate or meaningless, unless accompanied by a specification of all the attendant conditions on which that value depends, and that a full specification of those conditions is not a mere piece of scientific pedantry, but a necessary and inevitable corollary of the statement itself. In the case of a boiler, these attendant conditions are curiously complicated. Great results may be obtained from any boiler by observing what may be called freak or laboratory conditions, such as the provision of particular kinds of fuel, the maintaining of a certain thickness of fire, and constant attention in the way of stoking and cleaning, regulation of draught, cooling of firebars, and so on; but if in order to obtain these results conditions must be observed which are impossible to maintain in practical use, it is entirely useless for our purpose either to investigate or to specify them. What we require is the power of the boiler when properly erected, and worked under such conditions as an ordinary intelligent caretaker can observe without an inordinate expenditure of time, trouble and attention, and without the danger of burning the firebars. It is these practical considerations which make the matter so extremely difficult. There would not be much difficulty in defining the conditions necessary for obtaining the best result, but how can one specify exactly the conditions which must be observed by a caretaker, especially as the whole result depends very largely on the conditions which are actually observed? There are many practical questions of primary importance which must be considered in connection with this matter. Boilers differ very materially in the ease with which the flues and the firegrate can be kept clean from soot, dust and clinker. If then there are two boilers of equal power when perfectly clean, other things being equal, the boiler which can be most easily and thoroughly cleaned will in practice give better results than the other. How is it possible to take any account of this difference in any system of rating which can be devised? Then again of two boilers one might be of appreciably greater power with one kind of fuel, while with another kind of fuel the second one might be just as much in excess. Similar differences might arise owing to the greater liability of one boiler to lose efficiency owing to furring and other causes.

Quality of fuel.—This question is one of primary importance. By the quality of fuel I do not mean merely the number of B.T.U. which can be obtained by the combustion of one pound of the fuel. There are many other important qualities, such as quickness of burning, closeness of texture, caking, smoke and soot producing, clinkering, and other qualities, character and quantity of ash produced, and so forth, all of which are of great importance. The boiler must of course be suitable for the fuel to be used with it if the best results are to be obtained.

Also an important question is in regard to the length of time one charge of fuel is intended to last. There are some fuels, such as anthracite nuts, which contain a much greater number of B.T.U. per cubic foot than other fuels such as coke. A charge of the former will therefore last a greater time than a charge of the latter. Again, some fuels are quite unsuitable for boilers with a particular kind of grate bars. Wide grate bars with large air spaces are wholly unsuitable for fuels which are already in or are liable to disintegration by heat into small pieces. Other fuels produce clinker or clinging ashes of such quality and quantity as will speedily clog up the air spaces of the grate if these are too narrow and produce much resistance to flow of air. Other fuels which are liable to give off gas are very dangerous to use with certain kinds of boilers and grate bars. I had one case under my charge where a vertical cylindrical brick-set boiler with cylindrical flues and narrow air spaces between the grate bars was used with a certain kind of fuel which periodically produced violent explosions in the flues—of sufficient violence to blow out the brickwork setting. The trouble was obviated by providing a different kind of grate bars, as the particular kind of fuel used was very cheap in the district, and could not have been changed without considerable extra expense in upkeep.

Elementary Facts.—Before proceeding to suggest methods of testing boilers, it will be well to emphasize the essential facts of the problem. To begin with, every pound of ordinary fuel used in a heating boiler gives off on complete combustion from 12,000 to 15,000 B.T.U. according to the quality of the fuel used. The proportion of this which can be utilised or transferred to the heating medium depends on the amount of arrangement of heating surface provided in the boiler. There is a certain minimum quantity of air required to bring about the complete combustion of the fuel, and every cubic foot of air which is passed through the incandescent fuel in excess of the minimum reduces the temperature of the products of combustion. The higher the temperature of the products of combustion after leaving the incandescent fuel, the greater is the rate of transmission of heat to the water, and the greater the proportion of the heat generated which can be utilised. On the other hand, if the quantity of air is unduly limited, especially with a thick fire, the complete combustion of the fuel is impeded, resulting in the production of the gaseous fuel known to chemists as carbon monoxide, and its escape unconsumed into the air.

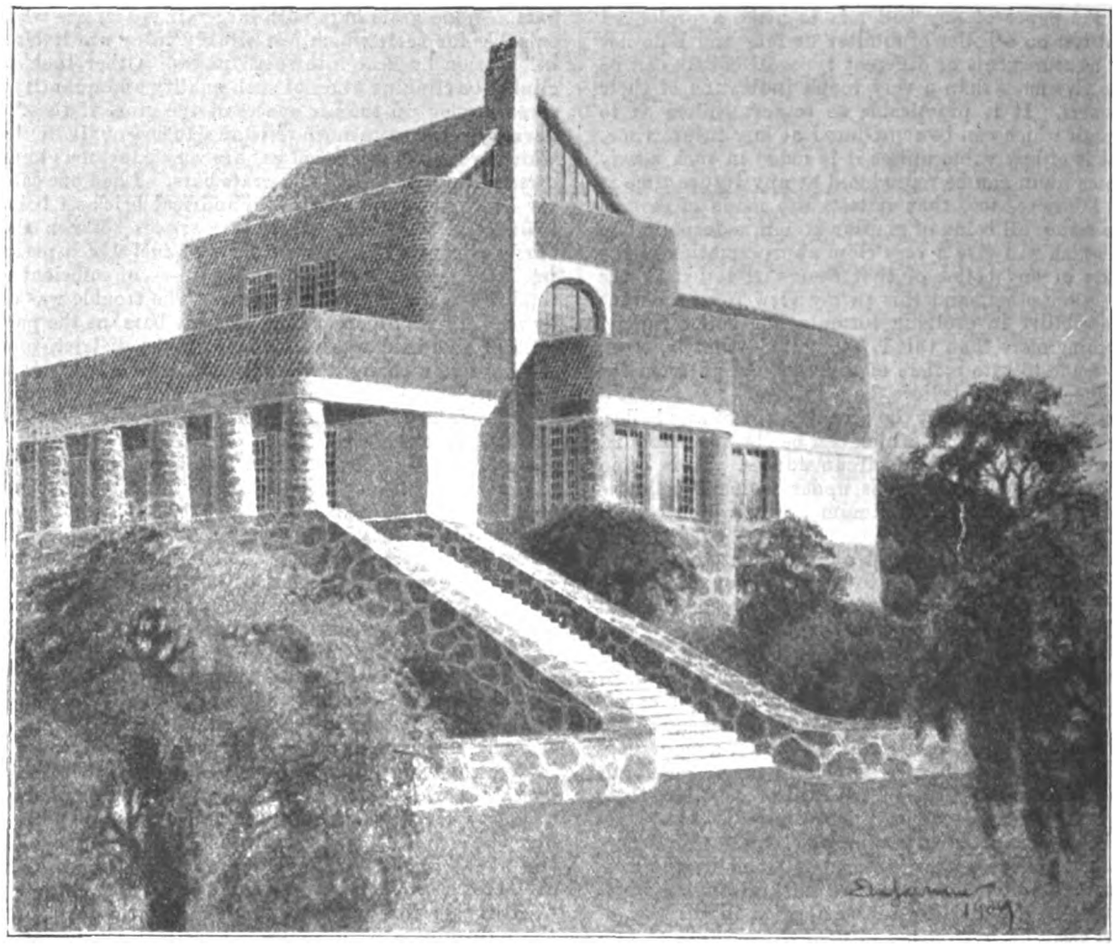
It is therefore evident that all combustion is in practice in the nature of a compromise. Practical considerations preclude us from utilising the whole of the heat derived from the fuel, or even from producing by combustion carbon dioxide only, free from admixture of surplus oxygen which reduces the temperature on the one hand, and of carbon monoxide which wastes the fuel on the other.

(*To be concluded.*)

NOTES ON BOOKS.

"An Architectural Handbook of Glastonbury Abbey." By Frederick Bligh Bond, F.R.I.B.A. (Bristol: Edward Everard. 2*s.* net.)

ANY work that Mr. Bond undertakes in the description of ancient architecture may be expected to be thorough, and this little architectural handbook does not disappoint the expectation. The exceeding antiquity of Christian worship and a Christian church at Glastonbury, with the evidence that is available, whether positive or circumstantial, is fully explained, and its character as British or Keltic brought out. The great abbey which, after the old church or churches and associated buildings had been destroyed by fire in 1184, was the glory of western England and the remains of which we see to-day is described in a full history or chronicle. The design of the abbey, necessarily in large part conjectural, is discussed and a detailed account or architectural survey of the ruins as they now exist is given at length. Thus we have an admirable manual invaluable to all who wish to visit Glastonbury with the intention of understanding not only what still remains, but what has existed in the past and made the fame of this interesting national monument.



"Stained-Glass Tours in England." By Charles Hitchcock Sherrill. (London: John Lane. 7*s.* 6*d.*)

The idea of arranging for the study of some of the most important examples of English stained-glass in a series of tours each devoted to one particular period of mediæval architecture is piquant and novel, but scarcely economical of time or of travel, and, as arranged by the author, practically only possible by motor-car. For example, Early English stained-glass is supposed to be studied by visits to Salisbury, Canterbury, Lincoln, and York. Going by road from Salisbury to

Digitized by Google

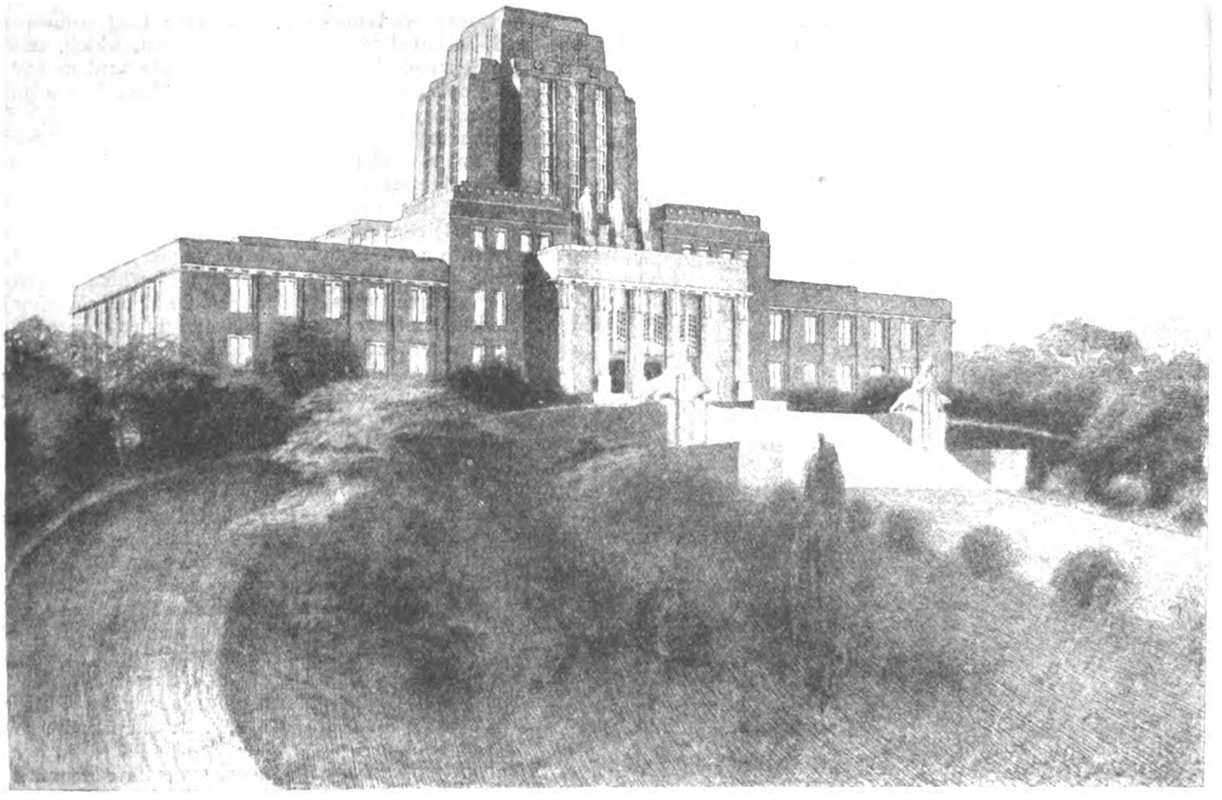
A SUMMER RESIDENCE ON THE LADOGASEE.
Eliel Saarinen, of Helsingfors, Architect. (From *Moderne Bauformen.*)

Canterbury one would or could without materially increasing the mileage pass through Winchester, Guildford, Gatton, and Knole, but all these the author omits from his Early English tour, and includes in the Perpendicular or the Renaissance trip. Then, in going from Canterbury to Lincoln, Cambridge is omitted, although on the direct road, because the glass that is to be studied there is Renaissance. By-the-bye our motor-car on this tour has to cross the Thames at Tilbury. Having arrived at York, we are permitted to start from there on our tour in search of Decorated glass because there is some at York, but we must not study the Perpendicular examples there. These we must leave to be afterwards seen in the course of another tour. The scheme of the tours then is, from a practical student's point of view, spoilt by the arbitrary pedantry of restricting the subject of study for each to one period, and indeed is of little value to anyone except those who are in need of an excuse for arranging motor-car trips. It is but fair to admit that in his description of the glass seen on any particular tour, the author does not scruple to include some of that belonging to an epoch not the main purpose of the tour. The description of the various examples of glass noticed is of the chatty and vague order, interspersed with tales and references that have nothing to do with the subject, hence of no value to the serious student, but interesting to the dilettante motorist who is only playing at the study of stained-glass and treating it, as we have already said, as a plausible excuse for the direction of his tours. The book does not possess the merits even of a good guide-book, for there is very little attempt to explain the subjects represented, still less at anything like serious criticism.



"Sketches and Studies of David Bles." (London: Alexander Moring, Ltd. The De La More Press. 3*s.* 6*d.*)

Ten years ago David Bles died at the ripe age of seventy-eight. For nearly half a century he enjoyed unfailing public favour in Holland as a painter. Yet his name is almost unknown outside that country, and is apparently in some danger of sinking into obscurity even there. The cause of this would seem to be that he never experienced the need of self-advertisement and, like the good-natured man that his photograph shows him to be, was content with a more or less local reputation. In addition his pictures were nearly always inspired by Dutch sources, and dealt with the middle of the eighteenth century. The present book with its introduction by one of his children has for its object to spread the reputation of Bles beyond the narrow boundaries of Holland. This is achieved to a certain extent by the introduction with its personal touches which arouse curiosity as to achievements of the genial artist. But that curiosity is only indifferently gratified by the forty-eight full-page sketches and studies. These are nothing more than working drawings, and are insufficient material for enabling the imagination to conjure up any idea of the completed picture. It is certainly true that they give an insight into "the way in which Bles set to work, of the care and thought he bestowed on his compositions, and of his powers of expressing the various characteristics of his manifold creations." But as it is admitted that his pictures are quite unfamiliar outside Holland, it might have occurred to the compiler that some reproductions of his finished work would have been acceptable among these often disconnected "notes." The sketches have, of course, technical interest, and suggest the high capabilities of David Bles. Indeed the effect is tantalising. The pictures, we are told, are mostly hidden in private collections. This being so, there is still greater reason to publish photographs of them.

The School of Architecture at University College, London, began work on Wednesday last. Professor F. M. Simpsnn attended on October 4 and 5 for the purpose of advisiog students as to their courses.

PARLIAMENT HOUSE, HELSINGFORS.
ELIEL SAARINEN, of Helsingfors, Architect. (From *Moderne Bauformen.*)

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *American Architect* has a description with several illustrations of the Luzerne County Court House, Wilkes-Barre, Pa., which is especially remarkable for the beauty of its internal treatment and for the painted mural decorations which are incorporated with its architectural features. A central area, surmounted by a dome, and with four courts radiating therefrom, produces a Greek cross plan. The exterior was designed by Mr. F. J. Oesterling, supervised by Messrs. McCormick & French, who are also responsible for the interior.

La Construction Moderne describes and illustrates the exhibition at Nancy, which is quite "new art" in a somewhat extravagant form. There is also an article on Old Paris, *apropos* in particular of the churches of St. Julien-le-Pauvre and St. Séverin.

The *Architectural Review* (Boston, U.S.A.) has in recent numbers dealt with the subject of modern gardens in an article by Mr. Thomas H. Mawson, illustrating which are views of Mr. W. H. Lever's garden at "The Hill," Hampstead; Mr. Ochs's house at Walmer Place; Mr. Robert Mawson's house at Windermere; "Fouracre," at Winchfield, of which Mr. Ernest Newton was the architect; Kearsney Court, near Dover; "Frithcote," Northwood. By comparison are given views of Mr. Platt's garden at Cornish, N.H., and plan of the gardens of the Luxembourg, Paris. Another number gives illustrations of an open-air exhibition of American sculpture held last year in Chicago, of designs submitted in the Boston College competition and of a stately mansion at Brooklyn, N.Y., for H. L. Pratt, Esq.

Berliner Architekturwelt has a rather miscellaneous collection of subjects, including the three premiated designs for church and parochial buildings for the community of St. Jacob, at Brunswick; a country house on the Kleinen Wannsee, the design of which is based on the version of eighteenth century English architecture known in the States as "Colonial," and several illustrations of architecture, painting and sculpture from the Berlin Art Exhibition of 1909.

Deutsche Bauzeitung continues the article on Frankish architecture, by Professor F. Ehemann, and gives a fine illustration of the interior of the monastic church of Ebrach, near Bamberg; also views of the picturesque Schloss Mespelbrunn, the old Rathaus, the Sandhof and the Marien Kapelle at Würzburg, and the portal of the parish church of Kitzingen. There is also a description with illustration of a rather striking small house at Pullach, near Munich.

Il Monitore Tecnico compares the international competition for the National Museum of Wales with that for a town school for the commune of Alessandria, being surprised with our method of awarding the job of carrying out the work for a building costing a quarter of a million sterling to the winner of the competition, although he may occupy no position of eminence in his profession. The school for Alessandria is to cost 400,000 liras, and all that the competitors are offered is one premium of 3,000 liras, and two of 1,000 liras. The Italian architects are fighting for an adoption of the English system, and our contemporary makes capital of the Welsh museum competition as an argument.

Construction (Toronto) has an interesting article on "The Missions of San Antonio," the eighteenth century Franciscan settlement in Mexico, with some pretty sketches of remains of the particular version of the Spanish Renaissance that formed the "mission-style" of California and Mexico.

The Budget and Private Enclosed Gardens.

SIR,—Though apparently the Government has withdrawn its proposals to tax enclosed private gardens, it still seems advisable that the attention of the public should be drawn to the dangers it has so narrowly escaped from such ill-considered propaganda.

Digitized by Google

MODERN EUROPEAN ARCHITECTURE.

FINLAND.

DETAIL FROM PARLIAMENT HOUSE, HELSINGFORS.
Eliel Saarinen, Architect.
(From *Moderne Bauformen.*)

The Budget proposed to doubly tax private enclosed grounds attached to "squares," "gardens," "crescents," and similar collections of houses. It claimed the right to do so, because these sanitary health-giving local lungs were withheld from the greedy speculations of the speculative jerry builder, and that these quiet, peaceful, picturesque areas are not available to the public.

Unfortunately, till quite recently town planning was neglected by our short-sighted municipal authorities. Indeed, throughout the United Kingdom the intelligent enterprise of far-seeing private individuals alone prevented local over-crowding and over-building by the costly creation—at their own expense—of numerous private enclosed gardens, managed and supported by local residents, paying enhanced rates and taxes because of the privilege of having sole access to these grounds.

Hence, to again tax these houses a second time by taxing their private enclosed gardens would be unjustifiable. It comes to this, that it has been suggested to put an additional tax on picturesque town-planning, tree-planting, hedges, grass, lawns, shrubs and flowers because these embellishments have been provided by private enterprise.

If the taxation of private garden enclosures were granted, then would it not follow that the taxation of houses bordering upon lakes, rivers, and the sea would also be retaxed, because of their adjoining aquatic air-spaces? Such taxes on air-spaces would be even more injurious to public health than the old tax on windows, which were guilty of admitting sunlight, warmth, and air.

To avoid noise and vibration created by "tubes," trams, trains, traffic, and motor-cars, I have long resided in a sheltered, secluded "square" in Brighton, which, in addition to extensive, elegant, enclosed private gardens and sea-terraces sloping down to the beach below, has a unique financial history that has hitherto escaped publicity. These Sussex Square Gardens, constituting the Kemp Town Enclosures, are a model miniature marine garden city, being Brighton's chiefest adornment.

Early in the nineteenth century Thomas Read Kemp (1781 to 1844) converted his Black Rock Farm and adjacent property into a magnificent estate, named after him, Kemp Town, the attraction and adornment of which are the enclosed picturesque "Sussex Square" Gardens, covering some ten acres, with their sea-terraces and grass-covered slopes, extending to upwards of half a mile along the beach.

The park was planned by Sir Joseph Paxton, including beneath the main road or sea front, a tunnel connecting the gardens with the marine terraces below. Under the highway on each side of the tunnel is a cleverly concealed cottage—like a cave dwelling—its roof being underneath the public foot-path above. The top of the "square" is nearly 120 feet above the sea's level. Sheltered from northerly winds by an ivy-clad wall some 35 feet high, the upper and lower marine terraces contain a dozen capacious arches providing excellent shelter and summer houses. This domain is only accessible to the residents in the 103 houses constituting this enclosed estate, the quiet and privacy of which pleased the King in 1908, when staying at the Duke of Fife's residence at the corner of "Sussex Square." By 1837 Kemp's magnificent town-planning punished him with a loss exceeding 500,000*l*. He died in comparative poverty in Paris in 1844.

For nearly a century these enclosures have been, and are, maintained by subscriptions from 103 owners and occupiers of houses on the estate. Their residents have paid extra local rates and taxes for access to the grounds, which yield neither income nor financial profit. Of course, this site can never be developed for building purposes, and to treat and tax it as land withheld from the market with a view to increase rent, is absurd. Indeed, already upwards of 40,000*l*. for wages and materials have been distributed for the upkeep of this park by the owners and occupiers of houses upon this estate, where empty untenanted houses also pay annual subscriptions for the maintenance of the gardens.

J. Lawrence-Hamilton, M.R.C.S.
30 Sussex Square, Brighton.

COMPETITIONS.

We have received from the Secretary of the R.I.B.A. the following announcement:—The Competitions Committee of the Royal Institute of British Architects are corresponding with the Warrington authorities with a view to the amendment of the conditions in this competition.

The Metropolitan Borough Council of Deptford recently organised a competition for a branch library at New Cross, S.E., and limited it to architects practising in the city and county of London. The first premium of fifty guineas has been awarded to Messrs. Castle & Warren, Talbot House, Arundel Street, Strand, W.C.; the second of twenty-five guineas to Messrs. H. W. Horsley & W. F. Young, 12 Norfolk Street, Strand, W.C., and the third of ten guineas to Messrs. Wills & Anderson, 24 Bloomsbury Square, W.C. The assessor was Mr. J. S. Gibson, V.-P.R.I.B.A. The drawings will remain on view until Saturday next.

The academy committee of Hamilton Burgh School Board, N.B., recommend the adoption of the design of Messrs. Cullen, Lochhead & Brown, architects, Hamilton and Motherwell, for the new academy which is to be built at Auchincampbell, Hamilton. There were thirty sets of plans from architects in Lanarkshire (including Glasgow), to which area the competition was confined. Mr. Bell, president of Glasgow and West of Scotland Institute of Architects, was the assessor. This design shows a building costing approximately 35,000*l*.

FORTHCOMING EVENTS.

Tuesday, October 19.

British School at Athens: Annual Meeting. Professor Gilbert Murray in the chair.

University of London: Carpenters' Company University Lectures on Architecture. Public inaugural lecture of this course by Mr. Halsey Ricardo, F.R.I.B.A.

Wednesday, October 20.

Royal Academy: Professor Arthur Thomson begins a course of twelve lectures on "Anatomy."

Friday, October 22.

Architectural Association: Paper on the "Architectural Association's Excursion to Cheltenham and District, 1909," by Mr. F. Dare Clapham, F.R.I.B.A.

Monday, November 1.

Royal Institute of British Architects: President's Opening Address. Presentation of the Royal Gold Medal to Dr. Arthur Evans, F.R.S. Address by Dr. Evans on "Recent Discoveries in Crete."

COMPETITION DRAWINGS FOR DEPTFORD LIBRARY.

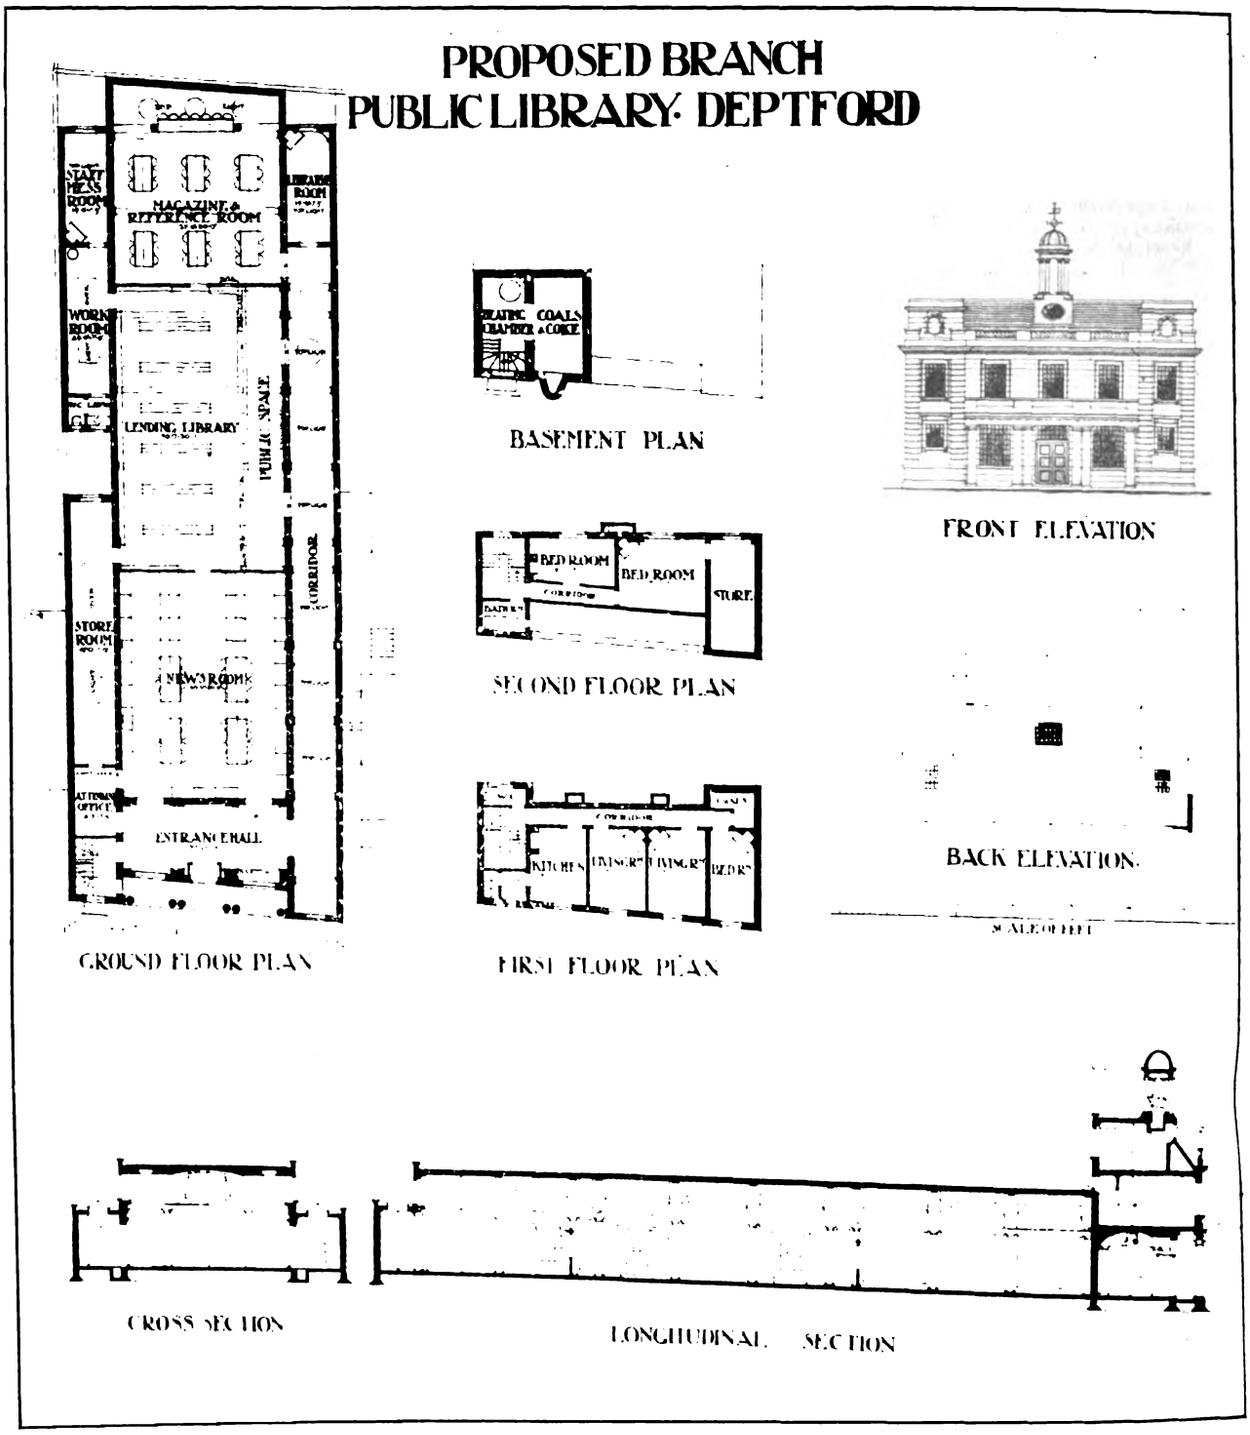
THE competition for a new branch library for the metropolitan borough of Deptford is interesting, not so much from the importance of the work as from the introduction, as far as we can remember for the first time, into the Metropolis of the principle of limitation that has now become very general in the provinces, particularly in Lancashire, limitation by geographical area of the architects permitted to compete.

In this instance only architects practising in London were allowed to send in designs for a building to be erected at the expense of London ratepayers, and although the sum to be expended, 4,500*l.*, is not a large one, the metropolitan borough of Deptford has reason for satisfaction at the response to its invitation. Sixty designs were submitted, and although, as in all small competitions and some large ones, there are a number of drawings evidently the work of tyros, who would be employing their time more advantageously in making designs under the supervision of a master in a school or studio, there are very many excellent schemes and drawings which must have rendered the work of the assessor, Mr. J. S. GIBSON, particularly difficult in selecting the best.

The nature of the problem did not admit of many solutions of a satisfactory character that should depart from the fairly obvious type adopted by the winners, and accordingly most of the meritorious designs follow this treatment more or less closely. Indeed, this was so obvious and simple that several competitors seem to have thought it too easy, and endeavoured to depart therefrom by introducing various quips and cranks that have shown their ingenuity but ruined their chance of success.

On a narrow parallel-sided site of 50 feet frontage and about 150 feet depth, with front and back lines not rectangular with the sides, had to be accommodated the usual requirements of a branch library, news-room, lending library on the "indicator system," reference and magazine rooms, with the customary librarian's room, work room, store, staff accommodation, and caretaker's apartments. Light being obtainable only at front and back of the site, and the existence of some ancient lights that had to be respected, plainly necessitated a large portion of the library being top-lighted.

Desire for architectural effect has led some competitors to adopt a central entrance, but the narrowness of the site rendered it imperative for a decent plan to have the public entrance at the side. This is the disposition adopted by the winners, Messrs. CASTLE & WARREN, of Talbot House, Arundel Street, Strand. They have balanced this entrance with that for the caretaker, which is not only right as regards appearance, but enables the caretaker and his wife, as they should do, to reach their apartments without carrying their cabbages through the public rooms, as one or two competitors arrange.



The proper place for the news-room is as near as possible to the public entrance, and both the first and second premiated designs have it in the front part of the building. Then next in necessity for ready access comes the lending library, which must occupy the centre of the site, and the rear is left for the magazine and reference rooms, which thus have the advantage of the quietude that they require.

In Messrs. CASTLE & WARREN'S design the news-room is L shaped, with dimensions of 26 feet 6 inches by 37 feet 6 inches for the main portion, and an annexe 20 feet by 10 feet 9 inches. This form is not only more pleasing than a plain rectangle, but lends itself to more efficient supervision from the staff portion of the lending library, the size of which is 26 feet 6 inches by 45 feet, cleverly arranged so that it overlooks and serves all public rooms—news-room, magazine and reference rooms. The magazine-room in the first premiated design is 31 feet by 20 feet 6 inches, and the reference-room 23 feet by 16 feet. The main corridor is a good feature in the successful plan, being 10 feet wide and comparatively short, the borrowers' space being arranged as a broadening out of the corridor. Thus a very excellent and simple plan results, and there is no question as to its suitability or superiority to others, although, as we have already indicated, there are not a few other designs which, following a similar disposition, run the accepted one very closely for pre-eminence.

Messrs. CASTLE & WARREN submit an alternative plan, of which the chief feature is a variation in the position of the librarian's room. In the primary design this is placed in a quiet and secluded position at the rear of the building; in the alternative it has a more central location. There are differences of opinion among librarians and among assessors on this point, and hence Messrs. CASTLE & WARREN were wise in proferring the alternative; but most modern librarians regard themselves as the organisers and business heads of their establishments rather than as supervisors, and hence prefer a room in which they can work quietly and with the minimum of interruption to one in which they can overlook the maximum number of departments.

The store room, work room, and staff mess room are in the first premiated design placed in the basement, whilst the caretaker's apartments, very amply and almost luxuriously planned, occupy the first floor over the front part of the building, and so help to make the elevation to the street. The treatment of the elevation is suitable and simple, in brick and stone, free from extravagance but sufficiently decorative to avoid meanness.

THIRD PREMIATED DESIGN.—DEPTFORD BRANCH LIBRARY COMPETITION.
Messrs. Wills & Anderson, Architects.

In the case of the first premiated design, although the conditions of the competition lay down that the attendant's office is to have oversight over entrance hall and news-room, this attendant's office is placed about 45 feet back from the entrance hall, and where the attendant could not give any supervision whatever. Also the librarian's w.c. and lavatory is not in conformity with the Public Health Act, inasmuch as it is toplighted, does not abut upon any yard, garden, &c., and has no window as laid down in the bye-laws. These points have been recognised and dealt with in the second premiated design.

The second premiated design, by Mr. H. W. Horsley and Mr. W. F. Young, of Norfolk Street, Strand, closely follows that of the winners in general arrangement, and is only slightly inferior in a few points. The main corridor is 9 feet wide instead of 10 feet; the supervision from the lending library of the other rooms is slightly less complete. The attendant is placed where he commands the front door rather than the borrowers' space, where at busy times he is, we think, more useful, for with the indicator system the staff behind the counter of the lending library is rather cut off from the borrowers. The elevation of this design is superior to that of the first premiated, but it is also more costly, being wholly in stone and with a range of Ionic pilasters, and at the present day it behoves borough councillors to avoid any possible charge of extravagance in architecture, particularly when, as at Deptford, they have built a town hall that, to say the least, does not suffer from parsimony of decorative treatment.

Messrs. Wills & Anderson, of Bloomsbury Square, have once again had the bad luck to obtain the third premium instead of the first prize. Their plan, as in the first and second, has the news-room nearest the entrance, lending library in the middle, and magazine and reference room at the rear. It has also the merit of providing the staff mess room, the work room, and the greater part of the store-

Digitized by Google

room on the ground floor instead of in the basement as in the designs placed first and second; but this involves a greater length of public corridor, an unremunerative part of the plan which is aggravated by a totally unnecessary entrance hall, introduced partly no doubt for the sake of a central main entrance and partly to get over the awkward skew line of the frontage. Their more fortunate competitors, by the way, have evaded this difficulty by sacrificing a small portion of the site. The elevation accompanying Messrs. Wills & Anderson's design is wholly in stone, dignified and severe to the point of austerity, with a colonnade between projecting end pavilions forming a portico entrance to the building. When one has only 4,500*l.* to spend there is little room for architectural luxury in a public library, and if unnecessary features either in plan or detail are introduced something else has to be cut down to pay for them.

Altogether we may regard this competition as satisfactory and a convincing proof that the public authorities of London can with advantage adopt the principle of limiting open competitions for their public buildings to architects practising in the Metropolis. We feel sure that no better designs adequately dealing with the conditions of the problem would have been received in this competition had it been made international instead of local.

We illustrate this week all three premiated designs.

NOTES AND COMMENTS.

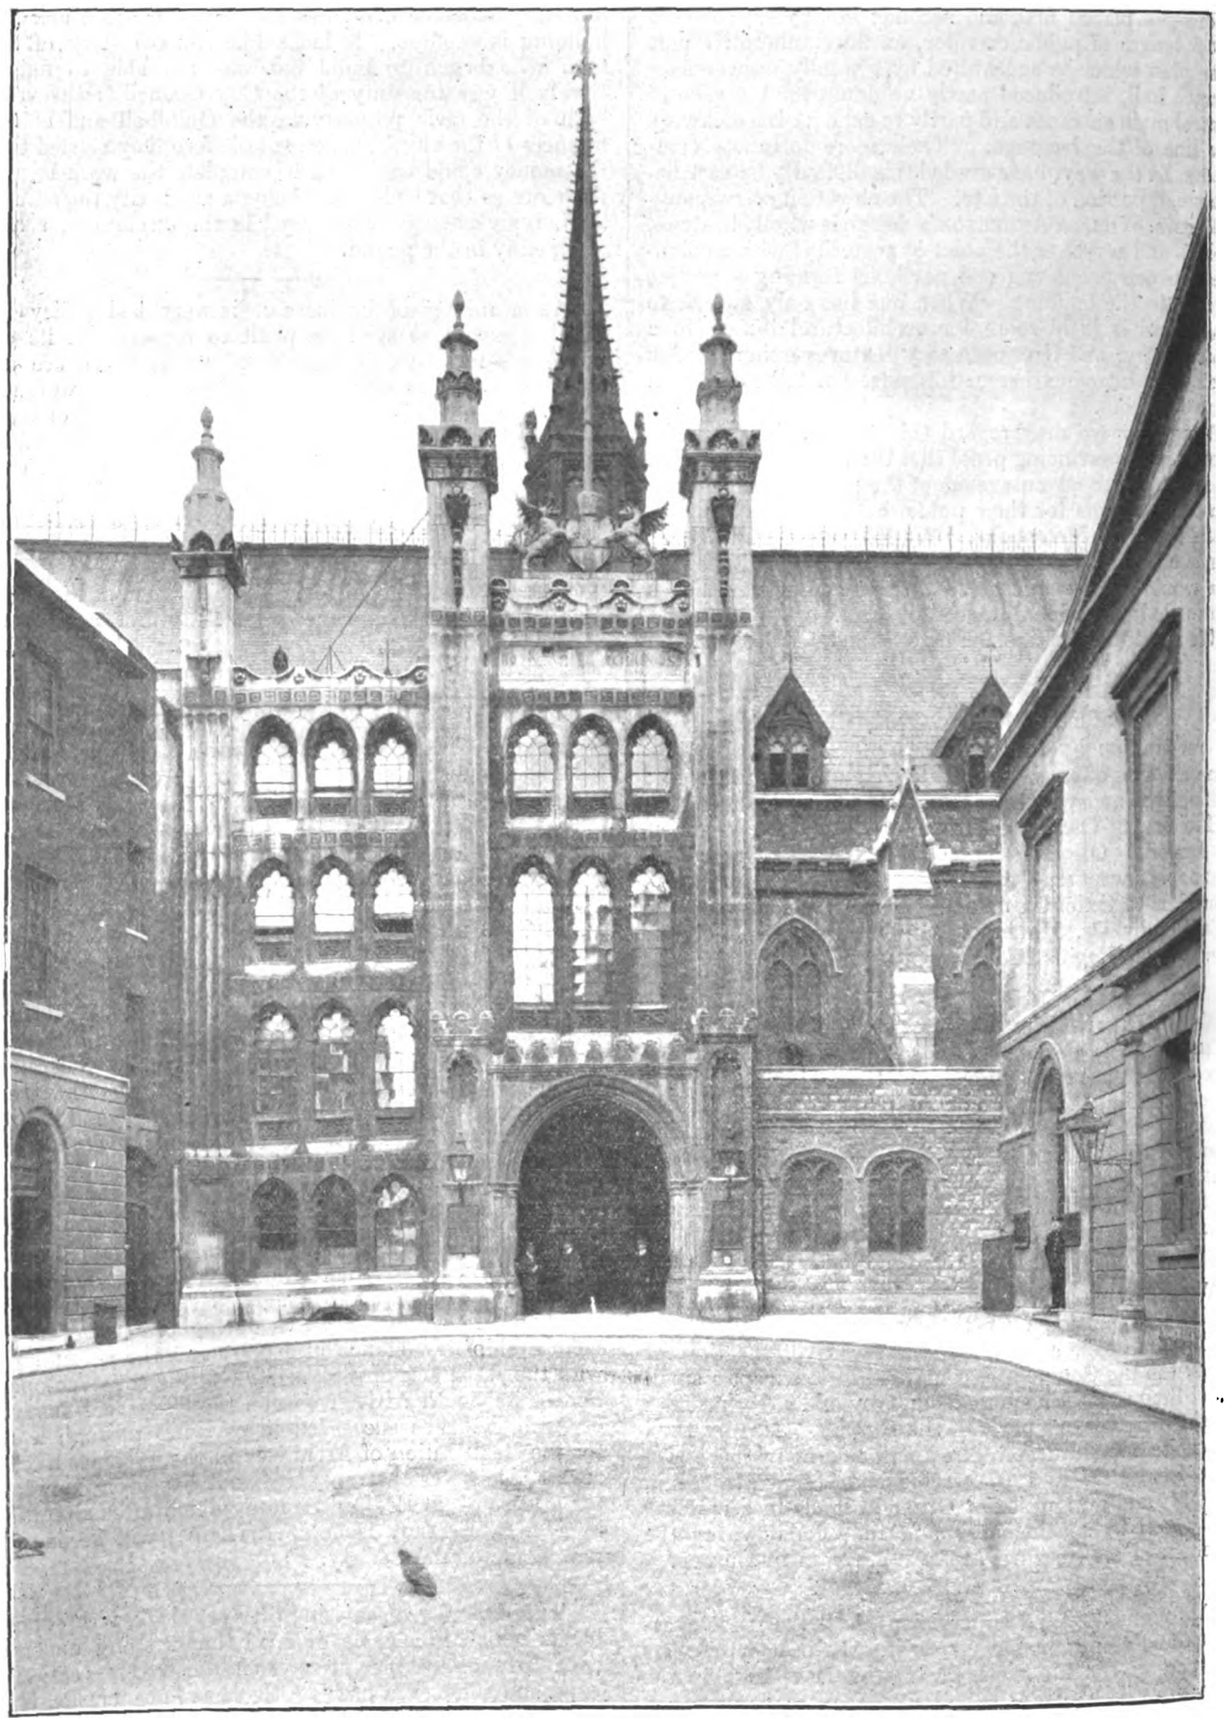
The recognition by the laity or non-professional public of the abilities of an architect is always to us a source of gratification, and we are pleased, therefore, to note that his Excellency Osman Hamdy Bey, Director-General of the Imperial Ottoman Museum of Antiquities, Constantinople, was on October 7 presented to the Vice-Chancellor of Oxford University for the honorary degree of D.C.L. by Dr. Holdsworth, Fellow of St. John's, acting for the Regius Professor of Civil Law.

Osman Hamdy Bey is an artist who, beginning life as an architect, developed into a painter whose works have constantly been exhibited at the Paris Salon, and twice, including the present year, at our own Royal Academy. He has made his mark as the organiser of the Service of Antiquities in the Ottoman Empire and the creator of a first-rate museum of Mohammedan art opposite the beautiful Chinly Kiosk within the Old Seraglio grounds of the Ottoman capital.

When, some thirty years ago, Hamdy Bey was appointed to preside over the Constantinople Museum, the Chinly Kiosk, a work of Persian art of the time of Mohammed the Conqueror, contained little except a small part of Schliemann's spoils from Troy and a few marbles brought from various parts of the Empire. Hamdy Bey, the architect and museum director, has now in successive stages from 1887 to 1907 erected and stored a museum of the art and antiquities of Ottoman lands in a building equal, both in spaciousness and in suitability for the exhibition of art treasures, to any museum in Europe.

The promotion and supervision of all the great excavations undertaken in Turkey during the past decade has been part of the life work of Hamdy Bey, notably the German, British, French, and American explorations in Mesopotamia and Babylonia, the German excavations in Cappadocia, the British at Ephesus and in Syria, and the French at Aphrodisias.

Undoubtedly in these times of general depression and shrinkage of incomes, the burden of "the rates" is becoming intolerable, but we cannot help regretting that the Chichester City Council has resolved, although by a bare majority of one, not to spend a further sum of 200*l.* in completing the restoration, or rather reparation, of the ancient Guildhall. The opponents of the expenditure seem to have committed the city to a peculiarly ridiculous *impasse*, for some 625*l.* has already been spent and the building is roofless. It looks like the old story of the man who began to build but was not able to finish. Surely it was the duty of the City Council, as trustees both of the civic property in the Guildhall and of the finances of the city, to make sure before they started that the money could be spared to complete the work begun, the more so that Chichester being a small city the sum of 200*l.* represents, as was stated in the discussion, a rate of a penny in the pound.



As a matter of business it is very bad policy for Chichester not to strain a point to preserve all its old buildings, for, save in Goodwood week, there are not many who visit Chichester except lovers of the works of antiquity; and Chichester, from a business point of view, ought to lay itself out to attract visiting tourists in default of other sources of income. The members of the Chichester City Council should spend their next holiday at Blackpool and study the municipal methods of that enterprising town.

The Liverpool Architectural Society, one of the oldest in the country, commenced its sixty-first session on Monday last, October 11, when a presidential address was given by Mr. T. E. Eccles, F.R.I.B.A. The Society appears from the report of the Council to be satisfactorily maintaining its position, as the number of its members has increased during the past year, and the balance-sheet shows an increase in the quite respectable balance of assets over liabilities, a balance considerably exceeding the whole of a year's expenditure. During the coming session papers will be read on "The Elements of Design in Internal Decoration," by T. R. Spence; "Reinforced Concrete and Steel Frame Buildings," by F. E. G. Badger, deputy city building surveyor of Liverpool; "The Development of Suburban Building Estates," by C. H. B. Quennell, F.R.I.B.A.; "Some Lessons from America," by Professor C. H. Reilly, M.A., A.R.I.B.A.; "The City Beautiful; or, Liverpool Compared with Cities Old and Modern," by Edmund Rathbone; "Architecture in Ireland," by Frederick Batchelor, A.R.H.A., F.R.I.B.A., President of the Royal Institute of Architects of Ireland; "Town Planning and Architecture," by Professor S. D. Adshead, F.R.I.B.A.

The twenty-fifth annual report of the Council of the Society of Architects makes note of two points on which the Society is entitled to congratulation—the first, that by an addition of twenty-five during the past year the membership now stands at 1,000; and the second, that with the assistance of the Society and the active co-operation of its South African branch the Transvaal Institute of Architects has succeeded in carrying through a Bill for the Registration of Architects in the Transvaal. The report also notes that an agreement has been completed for a lease of 28 Bedford Square, which after alterations by Mr. C. Fitzroy Doll, F.R.I.B.A., will become the new home of the Society.

The difficulty of devising a turret clock with exposed hands which is capable of good time-keeping under all conditions of weather, free from the adverse action of wind and snow, is a problem that has long puzzled horologists, who to effect a solution have for many years past applied themselves to the devising of some scheme by which, if possible, the time-keeping function of the clock may be separated from the hand-driving mechanism. An electrical turret system has now been invented by Messrs. Gent & Co., of Leicester, by which an entire dissociation of the time-keeping and hand-driving functions is effected. A full description of the mechanism of this system is given in the *Journal of the Society of Arts* for September 17. An installation of the system, known as the B.P. Patent Time Transmitter, has been made at the Merchant Venturers' Technical College at Bristol.

FRONT OF GUILDHALL, LONDON, AS AT PRESENT

PROPOSED IMPROVEMENT OF THE GUILDHALL, LONDON.

THE recent discovery of two fifteenth century windows in the Guildhall—concerning which an illustrated article appeared in our issue of September 24—acted as a reminder of the many vicissitudes through which the official palace of the Corporation of London has passed since its erection in 1411. The Great Hall, as it now stands, embodies the efforts of successive generations towards the maintenance and worthy improvement of this all-important part of the City's headquarters. The lower portions of the walls date back five centuries, as was shown by the windows mentioned above; while the open timber roof is just forty years old. This gathering together of

Digitized by Google

FRONT OF GUILDHALL, LONDON, AS PROPOSED.

many different periods is still further exemplified by the façade that terminates King Street and which forms so familiar a landmark. The porch which gives access to the Great Hall is part of the original structure. Superimposed on it and to the west of it is the front designed by George Dance the Younger in 1785, which completely masks the Hall behind. The portion to the east of the entrance is altogether unlike that on the west, and was one of the many changes carried out by the late Sir Horace Jones in 1868. As will be seen from our photograph, the presence of the Great Hall is revealed on this side by something more than the ridge of a high roof behind, for there are exposed the buttresses, windows, and dormers.

The incompetence of some masters in one style of architecture to understand the details of another is most

Digitized by Google

strikingly revealed by this maimed front. George Dance presumably believed he was producing something thoroughly in keeping with a Gothic structure.

Another instance of the same weakness that occurs to the mind is the west front of Westminster Abbey. It may here be mentioned that Wren left his mark on the Guildhall porch also, though with even less success than at the Abbey, for his Classic curved pediment on the original front makes no attempt to harmonise with the rest. The oriental character of Dance's original design was slightly subdued by the substitution of the present finials for what have every appearance of being stone palm branches. But whatever Dance did or did not do, he cannot be accused of initiating a front which concealed the fine Hall behind it. That fault was, for some unaccountable reason, perpetrated by the original designers, who, like so many of the English mediæval architects, seem to have given no thought to the dignity gained by a building when set down in an open space which would allow the eye to see it as a whole instead of in fragments. The present approach from Cheapside is altogether unworthy of a building in which are centred the powerful guilds of the City of London. Contemporary architects on the Continent had far more exalted notions of the fine opportunity offered by their trade halls. Yet even the present approach, poor as it is, was not provided until 250 years later, when the Great Fire prompted the authorities to improve upon the work of their predecessors by cutting through the mean houses that stood between the entrance and Cheapside.

Sir Horace Jones indelibly connected his name with the structure when he designed the existing noble open timber roof. But, seemingly, he wanted to leave his mark on the exterior likewise. Beyond doubt, he was quite capable of producing a front that was of better Gothic than that contributed by Dance. What he actually did was to pull down the eastern portion and leave the other two-thirds standing as they are to be seen to-day. An entire lack of balance at once resulted. If he believed that he was bringing to light the original structure he was mistaken, for excepting detached pieces of stonework in the buttresses, it is all new compared with the date of the Hall's erection. It is difficult to understand the motive of his action. Dance's front is obviously bad Gothic; but it was, at any rate, in harmony with itself, and after sixty years had become part of the history of the building.

It is now proposed to undo Jones's work and revert to Dance's design. The scheme does not arise out of any sentimental desire to impress the beholder. It is merely a practical solution to the ever-increasing difficulty of providing necessary accommodation for the Guildhall officials. Mr. Sydney Perks, F.S.A., the City surveyor, has prepared plans for the erection of three storeys over the library corridor and carrying them for a short distance between the Art Gallery vestibule and the Great Hall. The design for the façade is similar to and completes the main entrance as put up by Dance. Apart from the æsthetic effect, it is extremely desirable that such extra space should be provided.

Among the improvements that Mr. Perks has effected since he came into office there is not one more important than his clearance of the crypt, which is now one of the most interesting parts of the whole Guildhall. Nevertheless, it is still encumbered with iron machinery ranged round part of the walls. At first sight these may be taken for mediæval torturing appliances wherewith reluctant citizens were induced to contribute to the City's welfare. However, they prove on examination to be merely mechanical aids to the preparation of the banquets served overhead. Under their real character of ovens, sinks, and grills they are incongruous in the crypt, and would be far better hidden away in the proposed additions. Their place would be taken by the overflow from the adjacent museum, including the Roman masonry that is now stacked in a dark corner outside. The museum leads directly into the crypt, and the visitor would pass from the museum through the crypt and up the staircase into the Great Hall above.

Thus the scheme now proposed is to be commended both from the point of view of practical convenience and from artistic considerations. It is no small advantage to the dignity of the Guildhall of the City of London that its most interesting crypt should be rescued from the ignominy of serving as a lumber-room for kitchen utensils and fill the far better purpose of providing a suitable home for memorials of Roman and Mediæval London. It would also be a great gain to the approach to the Guildhall that the present lop-sided arrangement should replaced by the restoration of the symmetry of Dance's design, even though some purists for Mediæval architecture may—and we admit justly—criticise the detail which that architect introduced. George Dance was one of the architects of the past of whom the City of London may justly be proud, and it is but fair that now Newgate has gone, one at least of his works shall be again brought back to the form in which he left it.

THE ARCHITECTURAL ASSOCIATION.

THE opening meeting of the Session 1909-10 of the Association was held on Friday evening last in the premises of the Royal Architectural Museum, Tufton Street, Westminster, Mr. Henry Tanner, F.R.I.B.A., president, in the chair.

The Hon. Secretary announced a meeting of the Debating Society on October 15, at 7 p.m., when Mr. E. Greenop would contribute a paper on "Competition—Open v. Limited." He also gave notice of an exhibition of sketches in connection with the Camera and Sketching Club, to be held on October 21, at 8 p.m.

Messrs. R. V. T. Sewell, S. M. P. Sheppard, H. C. Hunt and E. C. Francis were elected members of the Association.

On the motion of the President a vote of thanks was passed to Mr. James Williams for presenting a water-colour drawing by Girtin.

The President then distributed the prizes and medals gained by students in the examinations.

Prize List.

A. A. Travelling studentship, value 25*l.*, and medal, G. G. Wornum. Second prize A. A. travelling studentship, value 5*l.*, C. G. Boutcher. A. A. Essay prize, value 10*l.* 10*s.*, and silver medal, H. F. Murrell. Banister Fletcher bursary, value 26*l.* 5*s.*, and silver medal; book prize for first place, advanced physics, W. J. Durnford. Architectural Union Company's prize, value 20*l.*, L. M. Gotch. Hon. mention, Architectural Union Company, and special prize, value 5*l.* 5*s.*; book prize, fourth year evening school, B. F. Matthews. Special prize, Saxon Snell studentship, value 10*l.*, R. Cromie. Elementary class of design prize, value 3*l.* 3*s.*, and bronze medal, W. D. Cathcart. Advanced class of design prize, value 5*l.* 5*s.*, and bronze medal, Alan Snow. First year day school, book prize for first place in history test paper; book prize for first place in construction test paper; prize for first place in perspective drawing test, E. L. Apperly. First year day school, book prize for first place in construction test paper; studio prize for best portfolio of drawings during session, R. C. Stevenson. First year day school, book prize for first place in geometry, T. F. Ford. First year day school, book prize for first place in physics, C. Rowntree. First year day school, volume of A. A. Sketch Book for first place in freehand drawing test; special studio prize, A. E. Maxwell. Second year day school travelling studentship, value 15*l.*; book prize for first place in intermediate physics, F. A. Crouch. Second year day school, first place in "End of session test," H. B. Chisholm. Second year evening school, scholarship, value 15*l.* 15*s.*; book prize for first place in preparatory physics, D. J. S. Dawson. Second year evening school, book prize, H. D. Kidd. Second year evening school, master's prize, H. V. C. Curtis. Third year, evening school studentship, value 15*l.*, P. D. Hepworth. Third year evening school, book prize, H. E. Moss. Third year evening school, master's prize, H. A. Gold. Fourth year evening school, travelling studentship, value 15*l.*, C. A. Farey. Fourth year evening school, master's prize, R. M. Pigott. Book prize for first place in elementary construction, Norman Keep. Book prize for first place in geometry, G. H. Inman Book prize for first place in Greek and Roman

Digitized by Google

architecture, G. M. Eaton. Book prize for first place in Greek and Roman architecture; book prize for first place in Renaissance architecture, R. N. Jackson. Book prize for first place in Early Christian and Gothic architecture, C. W. Rogers. Book prize for first place in English architecture; book prize for first place in materials, P. J. Adams. Book prize for first place in drainage, H. A. Thomerson. Book prize for first place in ventilation; book prize for first place in iron and steel construction; book prize for first place in advanced construction; book prize for first place in architectural features; book prize for first place in professional practice, G. Flint Clarkson.

The following students have been recommended by the Visitor, Mr. Ernest Newton, for the Board of Architectural Education Certificate, which entitles them to exemption from the R.I.B.A. intermediate examination:—R. W. Cable, G. F. Clarkson, C. A. Farey, A. V. Sutherland Graeme, G. W. Home, G. D. Gordon Hake, L. Keir Hett, T. A. Lodge, B. F. Matthews, C. E. Fellowes Prynne, I. M. Pritchard, R. M. Pigott, A. D. Robinson, F. H. Swindells, and E. J. Tanner.

The following students have been awarded the Association two years' course certificate:—E. S. A. Baynes, A. G. Butler, J. A. Cheston, H. B. Chisholm, F. A. Crouch, B. P. Gaymer, J. O. B. Hitch, L. D. Martyn, E. W. Mountford, C. W. Rogers, S. E. Shurmur, R. Talvalker.

President's Address.

Gentlemen,—In addressing you to-night, as is the custom for your President at the first meeting of the session, I am deeply sensible both of the honour you have done me and the responsibility which you have laid upon my shoulders—a responsibility which, without the help of many kind friends interested in the Architectural Association, I should not feel capable of undertaking. Knowing the loyal support which I shall receive from everyone, I am sustained by the hope that I may satisfactorily discharge the duties which naturally devolve upon such a position as this, which I am indeed proud to hold.

I feel great diffidence in addressing a body of men from the bulk of whom, at any rate, I should be only too glad to learn; but I venture to aspire to at least one qualification, and that is my desire, or rather my determination, to do my utmost to advance the Architectural Association's interests in every way that lies in my power, and any work in this direction will be a great pleasure to me, as it always has been in the past, particularly to all my predecessors in this chair.

My task is made no lighter by having to follow in the footsteps of our late President, Mr. Walter Cave, who filled the office with such success and general satisfaction that he has made it very difficult for his successor to approach the standard he has set, to say nothing of acting up to it, far less surpassing it.

My only claim to be in the position in which I find myself to-night is that for some years past I have been intimately connected with the administration of this large and important institution, and, generally speaking, have some knowledge of the workings of the Architectural Association, from which experience I am able to locate our weak points, which I am happy to say I consider to be few, and also to appreciate our many good and beneficial ones, which to me seem to exceed by far the former. I do not say this with any wish to flatter the Association, but I am giving my opinion for what it is worth, an opinion gained partly by experience, and partly by the appreciation and criticism of others which I have been privileged to hear—criticism which has been directed impartially and with a desire to assist us, and not to decry our efforts.

One of the first thoughts that occurs, I imagine, to the President of a society like ours is, "What sort of a Council have I to work with?" and in my case, I am glad to say, the consideration of this point is encouraging. The Council which you have elected, gentlemen, is one which compares favourably with any of those with which I have been acquainted during my years of office in other capacities. I am sorry to say we lose a few old friends—Messrs. Louis Ambler, A. Needham Wilson, W. Curtis Green, and W. Wonnacott, all of whom retired owing to our new legislation which limits tenure of office, the idea being to change more frequently the personnel of the Council, and to introduce new blood—a procedure, however, which I feel may not always be to our advantage when valuable members are thereby removed; I trust, however, that the new members of Council will not think by my saying this that I would for one moment desire their exclusion, for, on the contrary, I most heartily welcome them all—Messrs. R. Frank Atkinson, G. Leonard Elkington, Horace Field, Gerald C. Horsley, and H. A. Hall—and trust that they will find the work here as interesting and engrossing as the rest of us.

In Messrs. F. Dare Clapham and C. Wontner Smith I am endowed with two right hands, and in further adding to my support Messrs. Maurice E. Webb and Edwin Gunn as hon. secretaries the fickle goddess has dealt very kindly with me; for with these men and the rest of our very able Council at my back I am certainly well equipped (as far as the help of others can be desired) to deal with any knotty problems that may claim our attention during the session. The permanent staff, headed by Mr. Driver, whom I may refer to almost as an Architectural Association institution, has during my experience of it served us consistently well, and will, I have no doubt, continue to do so, although the increase and the importance of the work which has to be done must be felt by them as much as by the officers and Council whom you annually elect.

The duties of all honorary officers must have been very heavy before we had such a well-organised staff, and I often wonder how the duties of the Architectural Association's President of forty or fifty years ago varied from those which have now to be undertaken; I suppose the educational branch is the largest item, apart from the fact that the number of members is nearly doubled and the necessary incidental work thereby entailed greatly increased. We have, I am glad to say, two very early Presidents still with us—Mr. T. M. Rickman and Mr. R. Phenè Spiers—both of whom I am proud to call my friends, and I only wish we could have them with us here to-night and hear their views on the changes which have occurred in the Architectural Association since they held the reins of office. Speaking of forty or fifty years ago, I should like to remind you all that it is exactly forty years ago—some years before a goodly number of us here to-night were born—that the annual excursions were started, and as a proof of the keenness of the older members, I would like to tell you that one member, Mr. John Johnson, has not failed once to attend and work as hard or harder than any of us—a very remarkable record, and I trust he will be with us many years longer to set up an even more remarkable one, though I think it is already almost unbreakable, the only men likely to get near it being Messrs. Searles-Wood, Talbot Brown, Hennings, and Clapham.

The annual excursion is not supported nearly as well as I should like; it affords a unique opportunity of visiting private houses and many other types of building under particularly favourable circumstances, and I think all who have attended will agree that the week is one full of pleasure and instruction. This rather indifferent attendance is all the more regrettable when we recollect that only a few years ago, when a particularly interesting excursion was on the "tapis," there was a clamour that places were primarily allotted to those who usually attended, which, personally, I think quite right, as consistent support should always be recognised in a matter of this sort, and one cannot help noticing that the agitators at the time mentioned have been supporters neither before nor since.

On considering the general condition of the Association, we cannot, I am afraid, be altogether satisfied at present, for although we have wiped off the building debt, our annual balance has been decreasing rapidly, and what is worse, consistently; and, indeed, so serious do we consider the position that we are proposing during this session to thoroughly investigate the finance of all our departments, and put each section as far as possible on a more remunerative basis.

Our total membership this year shows a slight decrease, as we have had 132 resignations and losses, as against eighty-four new members, and I am very sorry to say we have lost by death several old and very valued members—Mr. Gruning, who was so universally respected, probably his name appeared in the bulk of cases during the last few years as arbitrator or third surveyor; Mr. J. W. Penfold and Mr. Cole Adams, former Presidents; and Professor Hulme, who for a long time was a valued member of our lecturing staff, are only a few of those whose loss we have to deplore.

This decline in our membership I attribute to the very long period of depression through which we are at present passing, and which is affecting so very adversely the most important trades in this country, among others the building trade; of course, architecture suffers at the same time. However, the historians will tell you that history repeats itself, and we know of similar periods of depression through which we have passed which have been succeeded by a flowing tide of prosperity, which I trust will be the fortune of our country—and incidentally ourselves—in the near future.

Digitized by Google

I am afraid that, like most professions, ours is overcrowded; but, as in other walks of life, there is always room at the top, so that we must not despair, but each of us make the top our goal, and be content with nothing short of that.

I regret that I must say that there is a certain slackness creeping in among some of the men who have done with classes and lectures, the men to whom to look to support the older institutions of the Architectural Association, the students' branches being as full of life and vigour as could possibly be desired. Every session sees the creation of some new club or section, rising, I was about to say "phœnix-like" from the ashes of its parent, but I must retract, for the parent Architectural Association is not in ashes but just a little inclined to be soporific. The most important case in point, to my mind, is that of the attendance and discussion, or lack of them, at general meetings, which ought to be far better attended. The papers for the coming session, I feel sure you will agree, are full of interest to every one of us, and I sincerely trust that the gentlemen who spend their valuable time in writing for us will have extended to them at least the courtesy of a good attendance. I have often wished that the Debating Society's meetings could be combined with the general ones, as the members of the former are undoubtedly very proficient at debate, and it would certainly be for the good of the Architectural Association generally that they should give us the benefit of their assistance.

The "Sketch Book" is not at all well supported. It does not even pay its way, and I feel sure that all here would be sorry to see the end of it, but that is what must happen unless a wider circulation is obtained. The illustrations are always good and well worth the guinea subscription. I should like to take this opportunity of thanking Mr. W. G. B. Lewis for the many years of strenuous work that he has devoted to the production of this valuable volume, and to express a hope that under the new régime recently organised it may once more recover the sound financial status that it once attained to under his care.

(To be concluded.)

THE CITY BEAUTIFUL.

ON Thursday of last week Sir Aston Webb, C.B., R.A., at Sutton Coldfield, as president of the Vesey Club, gave an address under the title of "The City Beautiful."

In his opening remarks he alluded to the dire results that have followed the uncontrolled extension of cities and towns in this country. England was behind most other countries in respect of systematic town-planning, in spite of the well-directed efforts to be seen at Bournville, Port Sunlight, Letchworth, and Hampstead. In most old cities there was a centre round which the principal buildings were grouped—the Greeks had their Agora, the Romans their Forum, the mediæval towns their market or cathedral place. Even London had fine centres at Trafalgar Square and the Mansion House, though they were not large enough to dominate the city as they should. Birmingham nearly had a very fine one, though unfortunately some recent public buildings had been scattered instead of being grouped round the Council House, and the church opposite had been removed. It was suggested that it would be better that a fine site for the Birmingham Cathedral should be acquired by one generation and the building left to the next rather than that both should be done inadequately in one.

Sir Aston Webb acknowledged the difficulty, if not the actual impossibility, of creating a new city in an old country like ours. But he pictured what might happen if a city swept away by fire were revisited fifty years later when it had been rebuilt under the guidance of a Commission of leading citizens and artists. The visitor would see something of this sort. The centre, he said, is on an eminence facing south. Round it are grouped the municipal buildings, the law courts, and the art gallery, also a municipal theatre and concert room and public gymnasium. The centre is laid out in terraces and flower gardens with fountains with plenty of water, the buildings have statues of famous citizens forming part of their architectural decoration. Trees are planted round, but regulated as to size. On the interior of the municipal hall, free to all, are emblazoned the names of local heroes who have devoted their lives to the city, as well as those distinguished in the service of the State. Above are portraits of leading citizens and frescoes by local artists of local history. From an archway in the centre of the south side of the square a great avenue some 200 feet wide starts. The centre has a double tram track with trees on either side, beyond on both sides a roadway and footways, and then a wide margin of grass. Down this avenue sites for further important semi-public buildings are found. The great avenue forms also a park-like promenade for the citizens and binds the whole city together as a unit. Outside this avenue lie the professional and commercial centres. The streets running east and west of this avenue are the shop streets with tramways down the centre. Further south is a belt of park land with a drive round the city in which are theatres and refreshment rooms, playgrounds, boating, and bathing. Beyond the residential quarter, with more shop streets running east and west, are the residential streets running north and south, so that the houses may get all the sun, for in "the city beautiful" the inhabitants believe "where the sun does not enter the doctor does." The residential portion is small in proportion, for with increased locomotion facilities more people live away; and for the same reason no huge barracks of dwellings for the working classes are required, and the factories themselves are less crowded into the towns. Two railway stations off the centre Mall, with large places in front, stop important vistas; the stations for heavy goods are in the manufacturing districts. Near the stations are the markets, one of the prettiest sights in the city. The tramcars pass through the centre of them. Churches and other places of worship are all given important positions, ending vistas or marking the junction of important roads. The design of these buildings, like all others, has to go before a commission of leading citizens and artists to ensure the general scheme of the city beautiful being retained. The schools are also on the tram routes. The manufactories are all to the north of the town, so that the prevailing south-west wind removes the smoke from the city, and the beautiful local stone remains clean and bright. To the north, in a beautiful garden, is the crematorium. In the residential quarter there is a total absence of front walls and railings, but instead grass margins to footways, and hedges mark the boundaries. Clear, bright water is sent down the road channels several times a day. No advertisements are allowed except on special places appointed for them, and even shop names and signs have to be submitted to the commission, as do all lamp posts, letter boxes, and other designs.

Such a city as that described, said Sir Aston Webb, could probably never be erected in England, but the extension of our towns could be regulated to their great advantage if strong local committees were formed in each town to rouse public opinion and to suggest to municipalities the lines on which improvements should take place.

LIVING ARCHITECTS.—NO. 18, MR. CHARLES HENRY HEATHCOTE, F.R.I.B.A.

MR. HEATHCOTE is a member of the firm of Chas. Heathcote & Sons, of Manchester, which occupies a prominent position amongst the architects of that city. The works carried out by the firm embrace a large number of manufactories, warehouses, insurance offices, banks, hospitals, and business premises, and are not confined to Manchester and its neighbourhood, but extend to Russia and Siberia. Mr. Heathcote's work embracing a large amount of engineering, he has studied his clients' interests by designing his own steelwork instead of letting the contracting engineers do it for him.

NO. 19, PROFESSOR F. M. SIMPSON, F.R.I.B.A.

PROFESSOR SIMPSON was the first holder of the Roscoe Professorship of Art to organise the now flourishing School of Architecture at Liverpool University. He now occupies the position of Professor of Architecture at University College, London, and is renowned for the excellent character of his writings as much as for his ability in teaching. He has established at University College a day school for architects.

ST. ALBANS CATHEDRAL.

UNDER the title of "Saints, Benedictines, Goths and Vandals," a lecture was given on the 7th inst. before the Royal Photographic Society at the New Gallery, Regent Street, W., by Mr. E. W. Harvey Piper, Hon.M.S.A. The address was illustrated by over one hundred lantern slides, many from recent amateur photographs and others made from drawings and engravings.

The topic of the discourse was the cathedral and abbey church of St. Albans, past and present. The story of the beheading of the British proto-martyr on the hillside ledge opposite the Roman city of Verulamium was rapidly sketched, and it was pointed out that while a little church rudely constructed of wattle and mud was soon afterwards erected on the site of Alban's death, no monastery was established until 490 years later, when Offa the Second of Mercia founded a Benedictine house as an act of expiation. Thanks to the prestige accruing from the custody of the saint's bones, the abbey became one of the most prosperous and wealthy communities in the Order; its abbot was mitred, and obtained, after tussles with Westminster and with Bury St. Edmunds, precedence over every other monastic establishment in England. The monks, drawn largely from the moneyed classes, numbered one hundred against the seventy usually housed at Westminster and the sixty at Ely, Gloucester, Norwich, or Winchester. The abbey church, built largely at first of Roman bricks quarried from the adjacent and deserted Roman city, benefited by the prosperity of the monks, and while ever restricted to its original narrow dimensions, was so added to eastwards that it became one of the longest in England. The builders were always more ambitious than funds justified, and every scheme for the improvement and decoration of the abbey church was starved in execution, and left half-completed. Forty abbots in turn reigned in splendour at St. Albans from 793 until December 1539, when Richard Boreham, of Stevenage, surrendered the abbey to Henry VIII., and was, together with his monks, pensioned off. The monastery buildings, with the exception of the steward's residence or Great Gate House, and the Water Gate, now the Fighting Cocks Inn, were granted by the king to Sir Richard Lee, who utilised them as cheap materials for other houses. The church, which in 1553 had been sold to the townsfolk for 400*l*, proved far too large for their requirements or power of upkeep, and only the central portion between the rood-screen and reredos was utilised for worship. The lady chapel was converted into a grammar school, and was shut off by a public passage-way cloven through the retrochoir, walled off, and providing a short cut for townsfolk from north to south. The western part of the nave, being disused and very poorly lighted, soon fell out of repair. Three centuries of neglect brought the great abbey church into a sad state of ruinous dilapidation, from which it was rescued by three successive generations of restorers, whose zeal often outran their knowledge and discretion. Lewis Cottingham in the forties of the nineteenth century displayed the typical ignorance of his day. Sir Gilbert Scott, during the twenty years ending with his death in 1878, evidenced great constructional ability in underpinning the central tower and pushing back into place the long bulging walls of the nave clerestory, not always combined with a tender regard for priceless fragments of old work. Then followed the tempestuous reign of Sir E. Beckett, afterwards Lord Grimthorpe, who, with an absolute disregard for the feelings of others, expended 140,000*l*. out of his own pocket in strengthening the fabric, in reconstructing the façades to nave and north and south transepts according to his own devices, and in re-edifying the lady chapel. Grimthorpe's drastic works at St. Albans twenty years ago evoked the most bitter storm of condemnation, abuse, and recrimination that ever raged about an architectural undertaking. The impression which some people had derived from the severe comments on his rebuildings that the church no longer contained old features of the first importance was, however, quite unjustified.

Two salient features characterise the laying-out—firstly, the great regularity, the only break of importance being the sixteenth-century Chapel of the Transfiguration, on the south-west side of the lady chapel, and, secondly, the extreme narrowness in proportion to length. The miserable and threatening condition of the bepatched west front of Wheathampstead was illustrated, and Beckett's crude design, prepared in 1877, was shown from his autograph drawing. That this was afterwards modified by an anonymous ghost, well paid to remain in obscurity, to the more presentable form in which it was carried out was obvious from the great disparity between the authorised version and the extended work, and from the fact that Beckett was so satisfied with this crude holograph design as the best he could produce that, thirty-four months after he drew it, he submitted it to the restoration committee for their approval without alteration or amendment. As for the west front as we now saw it, it was a passable example of the class of design adopted for a prosperous Nonconformist chapel in the closing years of the nineteenth century. The conception was well thought out, the buttresses to the central gable and its three doorways being boldly advanced, and the arcaded flanking wings over the aisles, reminiscent, to some extent, of the treatment of Salisbury's west front, being set back. The great nine-light window, with its wheel head, was cleverly recessed. The hexagonal flanking turrets were kept in the same plane of projection as the main façade and ended in bold spires, which, while providing the break so much needed to the flat sky-line of St. Albans, were tactfully kept lower than the apex of the central gable. Embedded in the central portal were considerable remains of John de Cella's work of 1214. Beckett pierced the western bays with entirely new windows, to the vast improvement of the internal illumination of that portion of the nave. The aisle walls at this end were unbroken by windows till within the last five-and-twenty years, for on the south side the abbot's lodge and hall (succeeded by a caretaker's cottage) abutted upon the church, and on the north side the outlying church of St. Andrew, built for the parishioners' use in the thirteenth century, opened out of the nave by an arcade of four bays. When this adjunct was destroyed in Elizabeth's time the space of the arcade was filled with a blank wall. A further stage in the restoration was the removal of the brick aisle parapets and their reroofing—with lead—by Scott at the five western bays on the south side and on the other portions with brown tiles by Beckett. A striking illustration of Beckett's wanton iconoclasm was his treatment of the beautiful late fourteenth-century cloister arcading on the south aisle wall. When these cloisters were rebuilt—1396-1401—by Abbot De la Mere in the then fashionable 'Early Perpendicular style, the spacing of triforium and clerestory bays behind the north walls were disregarded. The pulling down of the cloisters by Sir Richard Lee in the days of Edward VI. left the arcading against the walls exposed, and the failure of these arches to synchronise with the windows above was evident. Beckett found it necessary to strengthen this aisle wall owing to the poor foundation, and constructed against it between each bay a bold, uncompromising flat buttress of flint and freestone, which disdained to accord with the old work around, and cut through the charming cloister arcading. At Gloucester in 1318 Abbot Thokey overcame a similar difficulty by the use of pierced buttresses—an expedient now being adopted at Winchester by Mr. T. G. Jackson—and it was suggested that a still better effect would have been produced by the use of more pronounced flying buttresses. It was strange that while the walls were being strengthened no attempt was made to take out and replace with rough masonry the Post-Reformation patches of red brickwork which here and there still disfigure the aisle walls. Probably if this were done many interesting fragments of carved stonework would be brought to light. It was a matter for gratitude that Sir Gilbert Scott left untouched the three easternmost lights on the south side. These openings, which illuminated the ritual choir, were shorter and smaller than the others, and were separated by broad, flat Norman pilasters built up, like most of the work of that date, of reused Roman bricks. The three clerestory windows in the western wall of the south transept are of similar early Norman character. On the other hand, Beckett enclosed the fine abbot's state doorway built by De la Mere about 1370 in a flat, projecting porch, in a style which he imagined to be Norman. But the portal was a trifling matter compared with the new façade to the south transept, with its grotesquely stiff angle buttresses with square pseudo-Norman pointed finials, and five long lancets, graduated without and uniformly stopped within the building at the ceiling level. Lord Grimthorpe, it was averred, carried the transept roof up to an unnecessarily high pitch so as to be able to boast that he had provided the longest lancets in England. Before the restoration was undertaken the eastern limb of the abbey was confessedly in a state as precarious as picturesque, while the degradation to which the fabric was subjected spoke eloquently of disregard and neglect not only of the stability but of the sanctity of the edifice. Turning to the repaired building, the sky-line was now absolutely changed. The brick battlements had disappeared alike from presbytery and transept parapets; spiky, bristly pinnacles of aggressive mien, and presumably in Grimthorpe's judgment of thirteenth century type, replaced the softened and varied outlines of the

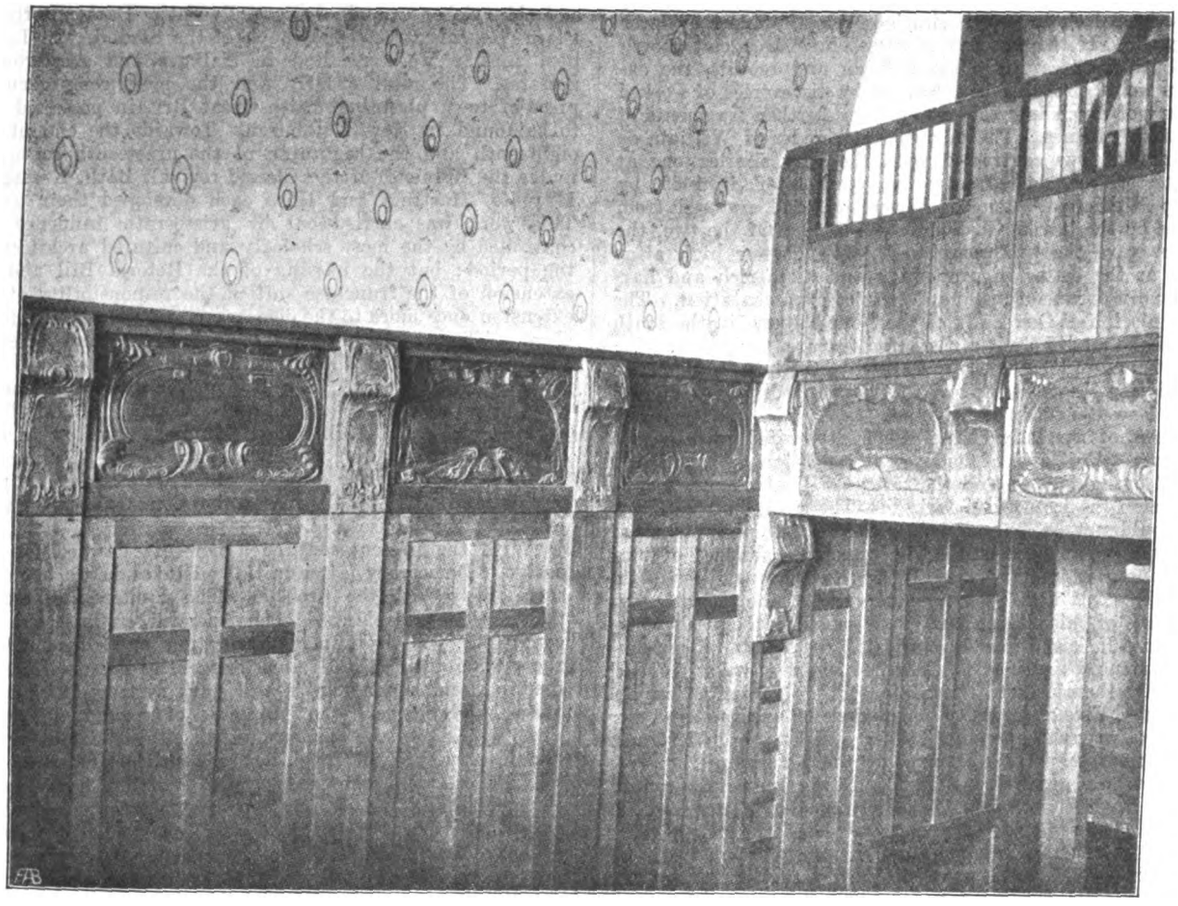
Ludwig Bernoully, Architect. [From *Der Profanbau.*



retrochoir; windows displayed new tracery borrowed from familiar textbook plates; while the north-eastern and south-eastern corners of the lady chapel were flanked by hard-featured buttresses, set at right angles like the revetments of a fortification. The walls of the little Transfiguration Chapel to the south of the main chapel had been lowered the better to clear the windows above, its east window was narrowed without obvious reason, and the chapel itself converted into a prosaic vestry. But the most startling change, apart from the transformation of the transept ends, was the new gable to the retrochoir, necessitated by the heightening of the external roof from the central tower eastwards. The additional gable at the east end contained a spherical window, cleverly adapted, it must be admitted, from those in the nave clerestory at Lichfield, but unique in its pattern. The three windows below this new light, which had long been blocked up as ruinous, were rebuilt and lengthened, and the end wall itself was prudently thickened. The lady chapel was vaulted in stone (in place of plaster), and a lead covering of unaltered pitch now replaced the mean slating. On the north side of the choir is a fine square-headed door of 1440, having shields in the haunch spandrels, in the one case charged with the three crowns of East Anglia, and in the other with the sword and key of St. Alban. In the north transept the pilgrims' portal, c. 1080, of re-utilised Roman brickwork, marks the route of pious visitors who, turning in from Church Street, bought their blessed candles there at the Waxhouse Gate, passed through the passage now misnamed the cloisters, and so by this doorway into the transept, and having viewed the shrines of Saint Alban and Amphibalus, and made their offerings, left by a doorway (now blocked up) in the south choir aisle. By working night and day, Sundays included, workmen under Chapple, by underpinning and grouting, prevented the imminent collapse of the central tower, the grandest and noblest feature of the abbey. At that time, 1870, Sir Gilbert Scott found that the mortar and filling of the tower piers had crumbled into dust, which was oozing through the cracks, and closer investigation showed that probably just after the Dissolution a deep hole had been cut in the south-eastern pier and filled with timber, now partly decayed, doubtless with the intention of lighting the wood and so felling the steeple. The tower was originally coated with plaster. This was renewed by Scott, but was afterwards scraped off the red brick surface.

The lecturer, discussing the general result of the restoration on which Grimthorpe expended like water the fortunes

DETAIL FROM HALL OF HOUSE AT SCHÖNBERG IN TAUNUS.
LUDWIG BERNOULLY, Architect. [From *Der Profanbau.*

he inherited, married, and made, held that they were indebted to the generous but self-opinionated and scantily-qualified benefactor for having soundly repaired the fabric, for putting in good foundations, and insisting upon sufficiently thick and well bonded walls and honest workmanship. It was improbable, had he not volunteered to the rescue, whether the funds for the absolutely essential structural works would have been forthcoming. Going into details, the lecturer held that the partial rebuilding of the lady chapel, its vaulting in stone, and its internal panelling and carving were admirable; the problem of the retrochoir was successfully treated; the west front was fair Late-Victorian work, but the cloister buttresses and Norman portals were blunders, and the rebuilding of the south wall of the transept with a novel, exotic, and uncongenial group of Brobdingnagian lancets, and the destruction of the character of the slype that abutted upon that wall were deplorable evidences of lack of judgment; while words could not be employed to express indignation at the inane, ignoble ignorance of the north transept "rose" window.

Examining from the entrance the north and south arcades by turn, the juxtaposition of Trumpington's Early English bays at the west end with Paul de Caen's heavy Norman piers and arches on the north, and with the elegant and enriched fourteenth-century ones of Eversdon and Mentmore on the south side, a rebuilding necessitated by the collapse of part of the southern arcade on October 10, 1323, was pointed out, and it was shown how closely those who reconstructed the work tried to assimilate it to that executed at the west end of the nave 120 years earlier by Trumpington. Turning westwards, the effect of Grimthorpe's end windows and new roof were admitted to be fairly satisfactory, while the greater stability and improved lighting of the aisles were very apparent. The unfinished pier bases put in by Trumpington at the west end showed his preparations for vaulting the nave, an undertaking which was happily abandoned, for the bad foundations and thin walls would certainly have resulted in the wrecking of the fabric had a stone vault been imposed upon them.

In the south nave aisle were seen the rich Late Decorated portal built by De la Mere in 1370 to serve as the abbot's state portal from the cloisters; the recessed tomb, c. 1455, marking the burial-place of the hermits Roger and Sigar, who flourished in the reign of Stephen. Proceeding into the south transept, Grimthorpe's alterations were only too evident; a passage-way in the west wall from the cloister has been converted into a cupboard, wherein is stored weekly the bread given to the poor under the will of Robert Stretton, 1628; the lockers in which the loaves are kept are small livery chests, the one hung on the north wall being of Elizabethan craftsmanship, the other on the west wall facing the doorway contemporary with the institution of the charity. The slype east and west entrances were also blocked up by Grimthorpe, and it has become a mere recess in the south wall of the transept; part of the original arcading is left on the south wall, while the other half-dozen intersecting arches are set up as an ornamental frieze on the south transept wall, below the "Five Sisters" lancets; the original western entrance to the slype, richly decorated Transitional work of 1140, now forms the central feature beneath these windows. The Saxon balusters in the triforia of the transepts seem to be relics of the earlier church built by Abbot Eadmer in the ninth century, and were probably incorporated into Paul de Caen's walling to demonstrate the historical continuity of the reconstructed church.

A series of three illustrations of the transepts looking to the north was successively thrown upon the screen to illustrate the changes effected during the past century. The first, an engraving by F. Nash, 1804, showed the crossing and transepts, encumbered with ramshackle, inartistic fittings. The second view was a photograph taken in 1870, when all the cumbrous Georgian furniture had been cleared away, and the whole area was left as a barren wilderness. The third, from a recent photograph, showed the present aspect of the transepts, relevelled, repaved, and receiled, the broad space broken up to some extent by open seats in the crossing. Looking from the ritual choir over the crossing eastward the chantries of Ramrygge and Wheathampstead were seen in

Digitized by Google

detail, illustrating the advance in style during the sixty years which intervened between their erection, and also the very fine brass of De la Mere, now secured on the altar slab of Wheathampstead's tomb. Here, as at Rochester Cathedral, the structural choir area is shut off from the aisles by later solid walls. If the masonry in these blank arcades to north and south were carefully taken down and rebuilt, the explorers would probably be rewarded by discoveries of worked masonry of much interest—possibly by further fragments of the saints' shrines. The magnificent reredos of William de Wallingford was contrasted with the very similar one at Winchester, constructed some five years later, in 1485, by Bishop William Patten, of Waynflete, and restored from designs by the late J. D. Sedding in 1890. Of the two, the lecturer gave the preference to the Winchester high altar screen as the better in proportion and more rich and harmonious in arrangement and details of ornamentation. The triple piscina of Our Lady of the Four Tapers, in the south wall of the retrochoir is a charming feature, and the carving in its tympanum evidently suggested to the late G. E. Street a motif for the treatment of the tympana of the great hall of the Law Courts in the Strand.

Views of the lady chapel when desecrated by use as a grammar school and of its present condition as practically rebuilt brought to an end the series of illustrations, and in conclusion the lecturer remarked:—The study had not been, and could not be, exhaustive. St. Albans presents many problems yet to be solved. The numerous changes of plan and construction have not all, by any means, been satisfactorily explained. Then, on the site of the monastery to the south of this church, and imprisoned in the walls of the abbey itself, are probably concealed fragments of masonry and carving which may possibly be of intense value. Much remains, therefore, to stimulate further investigation and thought. Five-and-twenty generations of workers and worshippers wrought upon the fabric, and have each left upon it their own impress. Inspired by the memory of the protomartyrs, and utilising afresh building materials contemporary with those saints, Benedictines, Goths, and even the Vandals of our own time contributed to render this edifice a very storehouse and treasury, a veritable handbook and encyclopædia of architecture of every period from the Saxon kingship to the present day.

CIVIC DESIGN.

IN the Arts Theatre of Liverpool University, Professor S. D. Adshead on Friday last delivered his public inaugural lecture upon appointment as Associate-Professor of Town Planning and Civic Design to the University. The title of his lecture was "Civic Design," and it was illustrated with lantern slides. The lecture was open to the public without fee. A large attendance resulted.

Professor Adshead, in his opening remarks, said the present generation were too apt to associate existence with gaunt and ugly buildings, flaring advertisements, entanglements of electrified wires, collections of chimney-pots, crowded slums, jostling and noisy traffic, squalor and dirt. Instead of tacitly accepting all this a city should rather be considered as a chosen place wherein to dwell, as a rendezvous of daily entertainment, as a vast expression of the sympathies of the human race, as the greatest and noblest of works of art. The characteristics of a city expressed in its colour, its texture and its form reflect on the citizen himself. Its design, the grouping of its buildings and its outward expression are matters of vital importance to his well-being. That these should have been left in the past to blind chance to develop shows a lack of appreciation amongst those responsible for city building difficult to comprehend.

The establishment of a Chair of Civic Design in Liverpool marked a step in democratic organisation. If planned to a preconceived system, cities were the expression of a strong administration, whereas built up unit by unit they were the presentment of individual taste. The claim that in unfettered and unrestrained growth alone could be found the city of true expression was true only if the city were regarded as the expression merely of the individual, disregarding altogether the efforts of the citizen as a class. In a well-organised city the immediate requirements of the individual should be subordinate to the permanent requirements of the mass.

The first example of civic design in England was the formal planning by Inigo Jones of the Covent Garden Piazza and Lincoln's Inn Fields; it was followed by the efforts of Sir Christopher Wren. But London lost its chance through discarding the great scheme by Wren. In the eighteenth century a system of rectangular streets and spacious squares were spread out between Oxford Street and Marylebone, and we got Regent's Park, Portland Place, Regent Street, and much of the Strand. In Liverpool similar work resulted in Falkner and Abercromby Squares. The most orderly and the most comprehensive piece of town planning which Great Britain possessed was to be found in New Edinburgh. Towards the end of the eighteenth and the beginning of the nineteenth centuries, under the influence of the Classic revival, Bath, Ramsgate, Margate, Hastings and Hove each developed their towns. This work was carried out by aristocratic influence and controlled by the most scholarly and cultured architects of the period; but the passing of the Reform Bill and the extension of the franchise shifted the responsibility of city extension once more to the democracy and successful middle-class. They were practically uneducated, and extended their cities, erected their monuments, and laid out their streets without regard to association, æsthetic relation, or any other sort of cohesion. The Council of Edinburgh actually presented a Bill in Parliament to allow them to acquire and build over the open space on the south side of Princes Street—public grounds which were to-day the pride of Scotland. That Bill passed the Commons, but was rejected by the House of Lords.

With the present century a new era dawned for civic design. Democracy, after initial mistakes, began to grapple successfully with the problem. The fundamental requirements of a well-planned city depended on its sociological conditions. With proper distribution and communication the city simplified itself into residential districts, business districts and commercial zones, park systems and pleasure places. These were the essentials of communal existence over which, in the well-organised city, the municipality should have entire control. It was on the proper provision of these essentials that the physical health of a city entirely depended, and unless ample provision was made for their reception, moral force and intellect would undoubtedly suffer. Most of our larger cities, which have grown by leaps and bounds during the period of industrial prosperity that prevailed during the latter half of last century, require pulling down, Haussmannising, and re-erecting on intelligent lines. This was the work which the municipal authorities and the town planners of the future will be called upon to undertake.

THE ASSOCIATION OF ENGINEERS-IN-CHARGE.*

GENTLEMEN,—I fully appreciate the honour you have done me in selecting me as your President for the ensuing year, and shall do my best to maintain the high ideals which have been set before you by my predecessors in the chair. Although I am not new to the presidential chair of engineering societies, this Association is unique in its membership. Other societies contain engineers of all kinds: some who are good talkers—commercial engineers; some who are good schemers—who can get up a limited liability company to float their projects; some who are good designers—who can prepare plans for any work for which money is forthcoming; some who are specialists—who devote their time to carrying out one class of work; but you, gentlemen, are the engineers who have to maintain the work originated by others, who have to make it a practical success, who have to make good the shortcomings of the theoretical men, to remedy the defects of their designs, and to maintain everything in working order and in the highest state of efficiency. This is responsible work, but it is very interesting, and I have no doubt that you all feel a pardonable pride in the position you occupy.

I claim to have been an engineer-in-charge long before I joined your Association. From 1865 to 1877 I was assistant manager and afterwards manager of the outdoor department of Sir William Armstrong's firm, and was in charge of the erection of dock gates, bridges, hoists, cranes, hydraulic machinery of all kinds, and the fitting out of ironclads with guns. At the time of the construction of the Millwall Docks I was responsible for the daily work of fourteen foremen and 400 men, and these are my credentials for associating myself with you to-night.

In casting round for subjects upon which to address you,

* Inaugural address of the President, Mr. Henry Adams, M.Inst.C.E., M.I.Mech.E., F.S.I., F.R.San.I., &c., October 13.

it seemed to me that "Standardisation" was the keynote of the present age, and that a few remarks upon it might be useful. The earliest standard was probably the unit of length, but down to 1824 the only legal measure of length was "three barleycorns round and dry make one inch, twelve inches one foot, and three feet one yard." The first standard worthy of the name was a yard length marked on a brass rod by a mechanician named Graham, employed by the Royal Society in 1742. Two copies of Graham's yard, made by Bird in 1790, were legalised by Act of Parliament in 1824. Ten years after this the standards were destroyed by a fire which burnt down the Houses of Parliament; but the Royal Astronomical Society had an accurate copy, and at least one other was also in existence. From these, four Parliamentary copies were made and deposited respectively in the Royal Mint, with the Royal Society, in the Royal Observatory at Greenwich, and the Houses of Parliament. In form they are all bronze bars 1 inch square, each being 38 inches long. Near the ends of each bar there are two holes, in which are inserted gold plugs with fine lines engraved upon their surfaces, which lines are exactly one yard apart at a certain stated temperature. The Act legalising these standards was passed in 1855. The accuracy of the measurement adopted may be inferred from the fact that a change of temperature of only one-hundredth of a degree Fahrenheit was found to produce a sensible effect in the length, and this yard is now the British standard of length.

Approximate standard measures for public use will be found on the north terrace inside the balustrade of Trafalgar Square, where the Westminster engineers check their surveying chains before and after use; and also in the Guildhall of the City of London, which surveyors in the City find more convenient. A 100-foot steel tape may generally be found to be within $\frac{1}{8}$ inch of accuracy, a steel chain from $\frac{1}{2}$ inch to $1\frac{1}{2}$ inches, according to age and condition; while a corrected 66-feet Chesterman wired tape, after being used on wet grass and wound up again, was found two days' later to be 65 feet 4 inches long; and three weeks later, when tested again before use, was found to be 65 feet 9 inches long, or still contracted 3 inches owing to getting wet.

The method of estimating length by lines engraved across a bar is known as "line measure," and comparison in the case of the standard bars was effected by means of two micrometer microscopes reading to one twenty-thousandth part of an inch. Sir Joseph Whitworth, however, showed that the principle of "end measurement" was more accurate, and that the sense of touch, aided by mechanical means, was so much more reliable than that of sight, that he was able to detect by his measuring machine a difference of length of one-millionth of an inch. This remarkable feat was rendered possible by the means then available for producing true planes, which enabled apparatus to be constructed with almost absolute precision.

In 1840 Sir Joseph Whitworth introduced the method of scraping surface plates, instead of grinding them, to produce a true plane. He showed that to originate a surface plate it was necessary to obtain exact agreement between any two in a set of three, two only not being sufficient, as they might be respectively concave and convex, and be parts of a true sphere.

I have not found any record of the first introduction of plate and wire gauges, but fifty years ago there were in existence the Birmingham wire gauge, the Birmingham plate gauge, the Lancashire gauge, the music-wire gauge, the needle-wire gauge, and the Whitworth decimal gauge. The latter is the only one upon a rational basis, and as each number represents so many mils, or thousandths of an inch, it could have been made of universal application. The Birmingham wire gauge (B.W.G.) was the best known; but this gave way on March 1, 1884, to the Imperial standard wire gauge (S.W.G.). This and the standard sheet and hoop iron gauge, which came into use at the same date, are merely fixed sizes corresponding to certain dimensions, but proceeding by irregular intervals. For galvanised iron roofing the old B.W.G. is still largely in use, but for sheet zinc there is a special gauge which bears no relation to anything else. For sheet lead the weight in lbs. per foot super gives the designation, e.g., 5 lb. lead, which is simple and satisfactory.

The first notable and practically successful effort at standardisation, as we now understand it, occurred when Sir Joseph Whitworth introduced his standard screw threads for bolts and nuts (1841-57). When I was an apprentice it was a very common thing to find that the bolts and nuts by different makers were not interchangeable, and a broken stud in a cylinder-end meant not only drilling out, but tapping a larger hole, because there were no dies to make the same thread as before. Only a few of the best shops were at that time supplied with Whitworth stocks and dies and screw taps; now, as you all know, they are universal—in Great Britain, at least. The Whitworth standard is, however, not the only one we have in use at the present time for screw threads. That was for mechanical engineers, and may be called the "bolt" standard. In addition we have the Whitworth gas threads adopted by the tube trade generally, and the British Association gauge for apparatus screws, which is adopted by the Post Office Telegraph Department and most large electrical firms.

Mr. H. F. Donaldson, in a recent lecture to the graduates of the Institution of Mechanical Engineers on "Interchangeability and Methods of Securing it in Screw-Threads," said:—"It is impossible to overstate the value, not only to this country but to the world at large, of the work of Sir Joseph Whitworth. By his means standard length pieces, and machines of great precision for measuring and comparing them, were brought into practical use, and within the reach of anyone desiring to improve the quality of his work. He not only put these, but he put also upon the market plug-and-ring gauges nominally of true dimension, and, I believe, he also actually produced the equivalent of limit gauges, though he did not press this method of working upon the public view, perhaps because the general methods of engineering at that time were not sufficiently advanced, and did not seem to require it." In case there should be any present who are not acquainted with the object and use of limit-gauges, I may explain that the system consists of having, for every true dimension required, two gauges called "go" and "not-go" gauges, so made that one is larger by a defined amount than the desired dimension of the piece of work, and the other smaller also by a defined amount. There are two important terms used in connection with these gauges—"allowance" and "tolerance." "Allowance" is the intended difference in measurement between the diameter of a shaft and its bearing, or a bolt and its hole; and "tolerance" is the difference that may be tolerated in good work between the dimension desired and that achieved.

The economical advantages of standardisation must have occurred to every manufacturing firm very early in its career, although it may not have got beyond the elementary stage where the parts could be cast from the same pattern, and marked off from the same templates. The firm of Willans & Robinson may occur to you as one that carried this principle to its extreme limit of usefulness, where every part of an engine was gauged to the thousandth of an inch to be perfectly interchangeable at any time; and many of you probably know that our friend, Capt. Riall Sankey, was largely responsible for this happy state of things. While I was working as an improver in a piecework gang I was very fond of introducing marking-off gauges, self-adjusting lathe carriers, and other standardising and labour-saving appliances, leaving me with spare time which, I am afraid, was spent in "larking about"; at any rate, it led to my being reported by the ganger, who said he and the other members of the gang were "keeping me." This led to an investigation, when it was found that I had earned more than any others in the gang, and then they turned face and said I was "bringing down the prices." It did not, however, prevent me from endeavouring always to find the shortest road to efficient completion.

One of the most hotly discussed questions of standardisation was known as "the battle of the gauges." It referred to the gauge of the rails for railway traffic, and ended in the permanent adoption by Act of Parliament (1846) of the standard of 4 feet $8\frac{1}{2}$ inches between the rails for Great Britain, and 5 feet 3 inches for Ireland. The 4 feet $8\frac{1}{2}$ inches was called "narrow gauge," to distinguish it from the "broad gauge" of 7 feet adopted on the Great Western Railway, but discarded in May, 1892. A similar battle was fought over a gauge for the railways in India, where we have the broad gauge of 5 feet 6 inches and the narrow gauge 1 m. = 3 feet $3\frac{3}{8}$ inches, and now the battle ground has shifted to Australia, where there are about 7,000 miles of $3\frac{1}{2}$ feet gauge, somewhat less of 5 feet 3 inches gauge scattered over several divisions, and 3,472 miles of 4 feet $8\frac{1}{2}$ inches gauge in New South Wales. Besides this, there are eighty-two miles of $2\frac{1}{2}$ feet gauge, and twenty-three miles of 2 feet. Standardisation has been proposed, but no action has yet been taken. It has been generally stated that the 4 feet $8\frac{1}{2}$ inches gauge was originally adopted because it agreed with certain existing colliery tram lines; but my idea is that no one would fix upon such an irregular measurement, and that it is more likely derived from a 5 feet over-all measurement of the rails.

The formation of the Engineering Standards Committee by the Institution of Civil Engineers, at the suggestion of Sir John Wolfe Barry in 1901, was the first combined effort at standardisation, and the success of that body has been very marked. The main committee was reinforced by representatives of the Institution of Mechanical Engineers, the Iron and Steel Institute, the Institution of Naval Architects, and the Institution of Electrical Engineers; but besides the main committee, twelve sectional committees and twenty-four sub-committees have up to the present been formed to carry on the work. Some 280 engineers and others representing the cream of the experts in each branch have given their services freely to the work. They turned their attention first to rolled joists, and produced a very good list; up to that time the sizes and proportions of the various sections depended upon individual judgment, and there was no sort of agreement between the various makers. Besides rolled joists, all the common forms of section, angles, tees, zeds, channels, &c., were included, and later on, tables of their properties were given, viz., areas, weights, moments of inertia, section moduli, radii of gyration, &c. All this very much simplifies the work of designing, and has proved a great advantage to manufacturers. Those of you who may be acquainted with Skelton & Co.'s broad-flanged beams may have wondered at their exclusion from the standard list, seeing that their undoubted economy for many purposes is beyond all question. The reason given is that they can only be manufactured in a "Grey" mill under licence from the patentee, and that they are, therefore, at present not suitable subjects to include under a public standard, but there is nothing to prevent them from being adopted in suitable cases.

The British Standard Specification for Portland cement, which is No. 12 of the Reports, has been of very-far-reaching importance, and has done more than anything else to raise the quality of Portland cement. Formerly every architect and engineer had his own ideas, or borrowed some, with regard to the tests and other details mentioned in his specification, frequently providing the manufacturers with difficulties, but, perhaps, quite as often giving them a loophole for escape. If the standard specification had not appeared just when it did, the spread of reinforced concrete building construction would have been attended with much greater risk, and probably failures also.

The standard specification for structural steel for ship-building, boilers, and bridges, and the forms of standard tensile test pieces, have all been extremely useful. Then we have the specifications for tramway rails and fishplates, bull-headed and flat-bottomed railway rails, tubular tramway poles, pipe flanges and pipe threads, and various electrical matters. Stoneware pipes are not, perhaps, of such importance as many subjects that have already received attention; but there is a general consensus of opinion that they should be standardised, and it is probable that they will shortly receive the attention of the Engineering Standards Committee.

The *Engineering Record* points out that the standardisation of sections of iron and steel or the quality of cement is by no means all that has been desired in Great Britain, for there has been a certain degree of pressure brought to bear to standardise machinery. Early in the committee's work it was recognised that when the movement was extended to the form of structures or machines, there was risk of encroaching upon the domain of original thought and design. It was at first decided that only materials and sections should be dealt with, leaving to the engineer the decision as to how the standards should best be applied to solve the problems which he might have under consideration. In a rather strange way, however, a departure from this general decision was made quite soon. The Secretary of State for India requested the committee to prepare standard types for locomotives for the Indian railways. The consulting engineers of the Indian Government and the chief locomotive builders were accordingly associated with the proper sub-committees, and eventually a number of standard types of engines were designed, which have proved very satisfactory. This instance of the standardisation of complete machines, while not absolutely unique in the work of the committee, is nevertheless still looked upon as open to question as a regular policy, and no action has yet been taken on the request to standardise dynamos and prime movers. The danger of adherence to a standard after it is no longer serviceable has been recognised from the outset of the work of the British committee, like that of the American Society for Testing Materials, and consequently provisions are made for the reconsideration of every standard section or specification when the time is ripe for such action. Care has been taken, however, to safeguard this work of revision; for standards which are revised every year or so are hardly standards at all. It is believed that by having each of them prepared by a sub-committee composed of men representing engineers, purchasers, and manufacturers, all engaged in their daily work with the subjects in which they are dealing, the standards will be so well drawn originally that the necessity for their revision will not arise quickly.

(To be concluded.)

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *American Architect* illustrates three houses of various sizes from the Garden City on Long Island, New York, all of which are examples of the bungalow type of summer residence with the upper storeys in the roofs. Verandahs are naturally a great feature of the designs, whilst the interior finishings, though simple, are anything but lacking in style. An interesting and suggestive article is given on the lighting of churches.

La Construction Moderne gives us a description, with plans, details and views of a box built for Mr. W. K. Vanderbilt in connection with his racing stables at Saint Louis-de-Poissy from the designs of M. Henri Guillaume, who has adopted for his *motif* the French country house architecture of the period of Louis XIII. Our contemporary has an amusing short article on the use of lifts by the Romans on the authority of Commendatore Boni. On the subject of Old Paris there are notes of the Roman baths and the Hôtel de Cluny.

Deutsche Bauzeitung continues Professor Ehemann's story of Frankish architecture, dealing now with the period 1245-90, which the Professor styles the Free-Gothic; that from 1290 to 1400 the "flowering-time" or fruition of Gothic; and the later Gothic 1400-1530. There are some excellent illustrations, but these are mainly of the "barock" period of German Renaissance, notably the Schloss Weissenstein, near Pommersfelden, and some further examples from Würzburg.

Architekten und Baumeister Zeitung illustrates a competition design for the extension of the War Office building at Vienna by Hugo Jos. Teffer.

A Construcçao Moderna illustrates modern houses at Lisbon and Coimbra, besides some details of joinery of the maddest "new-art" type.

Het Huis devotes itself to two subjects in the current issue, the decorative furnishing of the interior of passenger ships and child-life amongst the ancient Greeks. The former is treated with simplicity and refinement without the expensive ostentation that is to be found in English and German trans-Atlantic liners. The latter subject is worked out from illustrations on Greek vases and monuments, with one or two examples from Roman work.

The *Architectural Record* commences a series of articles on "The Architecture of American Colleges" with an illustrated description of Harvard University, whose succession of buildings is a historical record of the progress of American architecture in college design. "The Work of Lewis P. Hobart" is an appreciation, fully illustrated, of one of the most prominent of the architects of San Francisco, whose work is remarkable for its quality.

The *Architectural Review* (Boston, U.S.A.) illustrates a charming little town house, the residence of Bertram G. Goodhue, a member of the firm of architects, Cram, Goodhue & Ferguson; also with great completeness of detail a town mansion, No. 844 Fifth Avenue, New York City, of which Mr. Charles A. Platt is the architect.

The *Engineering Record* gives an account of a particularly remarkable example of the typically American constructional feat of moving an entire building, in this instance the public library of Brookline, Massachusetts, which was shifted bodily to a new site without interference with its use by the public. A description is given of the new type of concrete pile in use on the Continent of Europe formed by the method known as the "Compressol" system. This has been largely employed in Paris, and is now being utilised for the foundations of the new wing of the Palais de Justice on the bank of the Seine.

At a Meeting of representative citizens and Guild Brethren held in Edinburgh last week, it was unanimously resolved to nominate Mr. J. Macintyre Henry, architect, 7 South Charlotte Street, Edinburgh, for the office of Lord Dean of Guild. Mr. Henry has been a member of the Dean of Guild Court continuously since November 1904 and of the Guildry since 1890.

FIRST PREMIATED DESIGN.—LAYING OUT LANDS AT THORNLIEBANK, GLASGOW, FOR THE HUTCHESONS' TRUST.
Messrs. J. Boyd & Co., Architects.

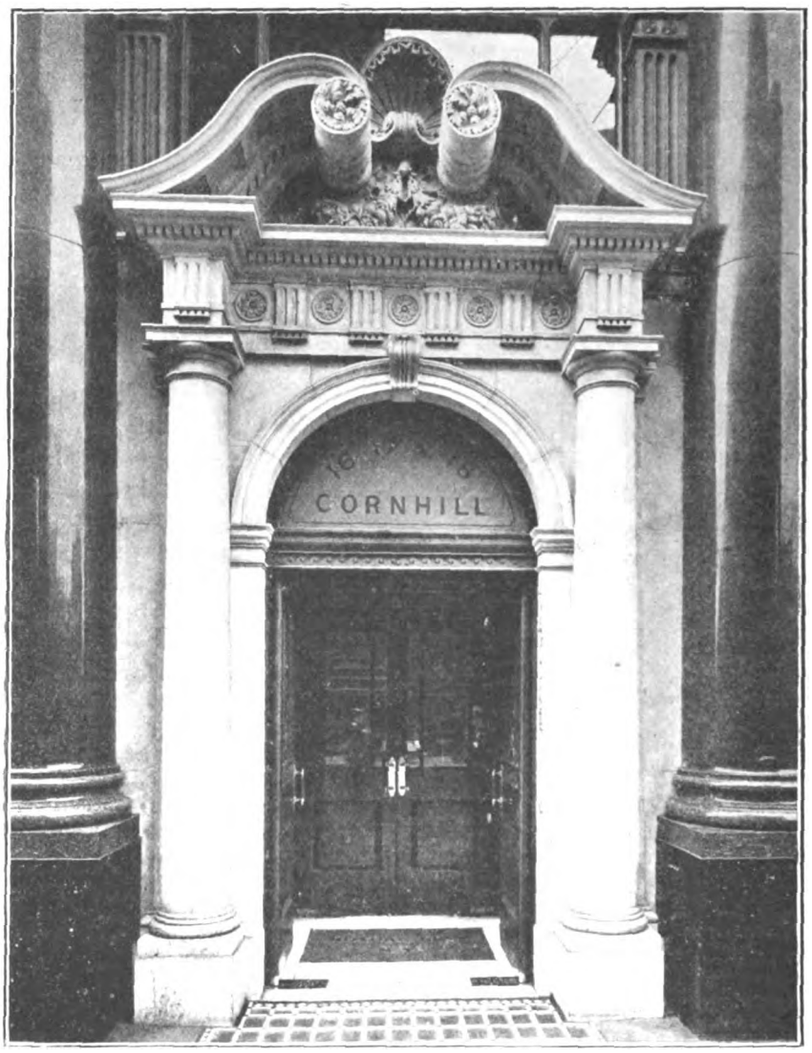
COMPETITIONS.

IT will be remembered that the assessor's award of the third premium in the Grimsby Town Hall competition was not accepted by the finance committee on the ground that the architects' estimate was considerably above the limit stipulated, and the assessor, Sir W. Alfred Gelder, F.R.I.B.A., was asked for an explanation. This came before the finance committee last week, and being considered satisfactory, the third premium of 100*l.* goes to Messrs. Rigby, Oliver & Phipps, of 92 Market Street, Manchester, for design No. 47.

The Hamilton Burgh School, N.B., have adopted the plans submitted in competition by Messrs. Alex. Cullen, Lochhead & Brown, architects, Hamilton, for the erection of a new academy at an estimated cost of 35,000*l.* The second place has been awarded to Messrs. H. & D. Barclay, 245 St. Vincent Street, Glasgow; the third to Messrs. Salmon, Son & Gillespie, 53 Bothwell Street, Glasgow; and the fourth to Mr. Gavin Paterson, Hamilton. The competition was limited to architects practising in Lanarkshire, and Mr. G. Bell, F.R.I.B.A., Glasgow, acted as assessor.

The awards in the Hutchesons' hospital feuing design competition were made at a general meeting of the patrons held on the 6th inst., at Glasgow, and the following are the names and addresses of the authors of the designs adjudicated first, second, third and fourth in order of merit, viz.:—First, Messrs. Josh. Boyd & Co., architects, 49 Bath Street, Glasgow (100*l.*); second, Mr. Daniel McInnes, C.E., 3 Kennyhill Square, Dennistoun, Glasgow (75*l.*); third, Mr. J. Gilchrist Bennett, C.E., 12 High Street, Paisley (50*l.*); and fourth, Messrs. W. R. Copland & Sons, C.E., 146 West Regent Street, Glasgow (25*l.*).

The successful design is shown above.



Correspondence

[The Editor will not be responsible for the opinions expressed by Correspondents.]

Herculaneum.

Sir,—A short time ago there was some talk of the Italian Government seriously undertaking the excavation of Herculaneum, the richest mine of art treasures in Europe. However, it is to be sincerely hoped that this scheme will be persevered in, and not be shelved as so many important schemes have been ("vita nostra brevis est, et Ars longa est"). This fine city has been buried for centuries under a stream of liquid lava. The sudden disaster prevented the removal of these art treasures, which have been preserved for hundreds of years, being cast out by a warm stream of lava, and must be in the same state as it was when the terrible disaster overwhelmed the city. Pompeii, its neighbour, was destroyed by a continued shower of ashes, but the inhabitants had time

Digitized by Google

DOORWAY, MUTUAL LIFE ASSURANCE COMPANY OF NEW YORK, CORNHILL.

to save most of their valued possessions before the city was buried. I believe one of the villas on the outskirts of Herculaneum has been excavated, when valuable manuscripts and art treasures were found in a perfect state of preservation. As most of us are aware, the Greeks introduced coloured architecture into Italy, and examples of their best work are buried in Herculaneum. When we come to consider the finely preserved work laid bare in Pompeii, how much better preserved must be the work cast out in lava in Herculaneum? The grand work Gell's "Pompeii," published some years ago, is a most valuable work of reference for every decorative architect, showing what a state of perfection decorative art had arrived at. After all said and done, we of the present day cannot improve upon it. Every true art lover must sincerely wish that the above scheme may be realised, and thus give to the world the treasures buried for so many centuries.—Yours obediently,

Henry H. B. Sang,
Architecte-Decorateur.

Texture.

Sir,—We notice in your issue of the 8th inst., in your leading article under the heading "Texture," a reference to Pentelikon marble, from which it would appear that some few doubts as to the durability of this material still linger in the mind of the writer.

In so influential a journal as *The Architect*, we do not think such a suggestion should be allowed to pass unnoticed, and therefore send you herewith a photograph of the doorway of the Mutual Life Assurance Company of New York, 16, 17 and 18 Cornhill. This was erected from the specification of J. Macvicar Anderson, Esq., F.R.I.B.A., now over ten years ago, in Pentelikon marble, and has been quite exposed to the ravages of the London atmosphere.

A glance at the carved details will satisfy the most critical that no sign of decay whatever is apparent, and a careful examination of the original will thoroughly confirm our statement that this beautiful material is thoroughly durable.

Another instance of the unsuitability for exterior use of white marble in London has been cited in the caps of the granite columns at the Sun Life Office, corner of Vere Street, Oxford Street. These have been fixed even longer than the porch above referred to, and have, we believe, never been touched. London dirt lies thick upon them, but the material itself is as sound and the arrises as sharp as the day on which they were erected.

We do not and never have claimed that Pentelikon marble will remain white, without attention, in London. One of its greatest merits is that it can be washed, and we therefore assert that if architects can persuade their clients to allot a small sum yearly for cleaning, then in Pentelikon marble they have a material that will maintain its own, and add to the beauty of London as no other building medium is capable of doing.—Yours faithfully,

Marmor, Ltd.

18 Finsbury Square, London, E.C.: October 12, 1909.

GENERAL.

The Directors of the London and Lancashire Fire Insurance Company have declared an interim dividend of 6s. per share (being at the same rate as the last interim dividend), payable on November 1, 1909.

The Glasgow Corporation will next week consider the following motion:—"That, in order that the purchase or acceptance of pictures and art objects for the Corporation collections may be put on a more satisfactory footing, it be resolved that a number of gentlemen of recognised taste and experience be invited to form an advisory committee to co-operate with the galleries sub-committee in the matter."

The Preliminary Work for the re-erection of Crosby Hall at Chelsea is now in progress. The houses in Danvers Street have been demolished, and the contractors have already excavated 20 feet of the foundations for the new hall. The actual putting up the building is expected to commence shortly, and the new stonework to take the place of the rubble walls is being prepared.

SCHOOLS FOR ARCHITECTS.—III.

LIVERPOOL UNIVERSITY.

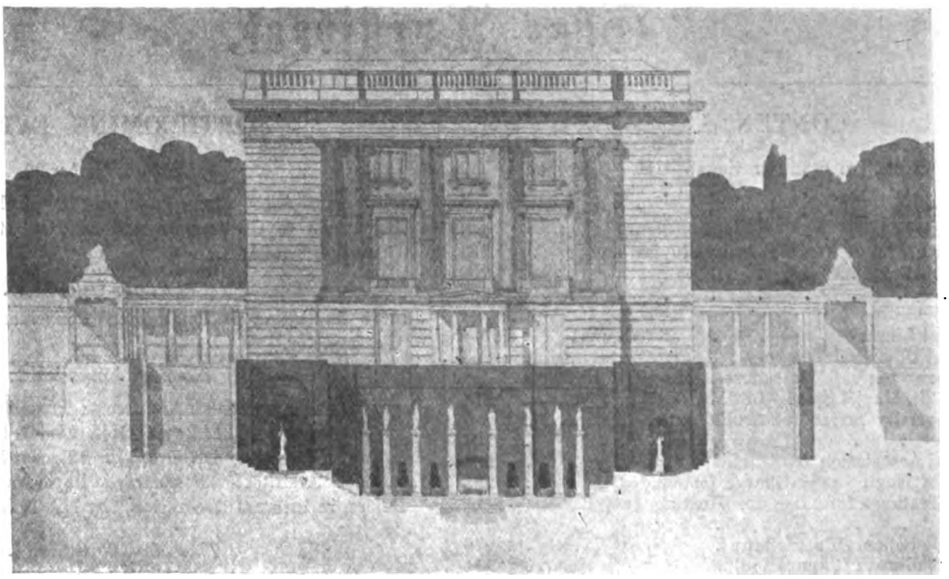
THE School of Architecture at the University of Liverpool is remarkable for the recognition of architecture as worthy of a degree on its own merits, and not as an offshoot or honours subject in a presumably superior department of knowledge. The young architect who obtains his early training at Liverpool University can obtain the degree of Bachelor of Architecture, not merely a degree of B.A.(Arch.).

To obtain the degree of Bachelor of Architecture five years' study and three examinations have to be passed. The first step, of course, as in all universities, is matriculation, by the passing either of the Matriculation examination of this University or of other approved and equivalent examination.

Having matriculated, the student starts work for the Intermediate examination, the subjects of which are (1) History of Architecture; (2) either Ancient History or Modern History; (3) either Pure Mathematics, Applied Mathematics, Physics, or Chemistry; (4) two subjects, one at least being a modern language, selected from Greek, Latin, French, German, Italian, Spanish, English Literature, Logic, Pure or Applied Mathematics, Physics or Chemistry (not, of course, duplicating the subject taken in section (3)). Thus the first year in the University course aims at extending the range of the student's general knowledge acquired at matriculation, with special reference to the study of architecture. During the time the first-year student is not attending lectures on these subjects of the Intermediate examination he is expected to attend the architectural studio.

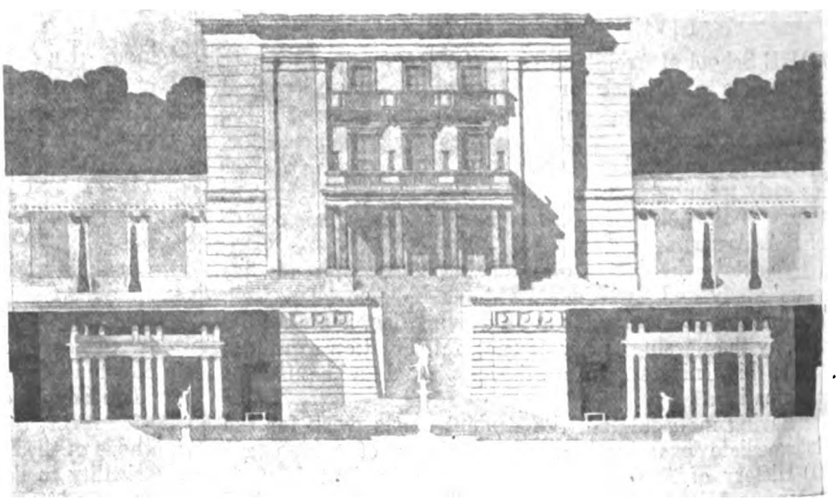
During his second and third years the degree student devotes his attention to more particularly architectural work and prepares for an examination in (1) History of Architecture, with special study of an approved period; (2) Architectural Design; (3) Building Construction; (4) Mechanics of Structures; (5) a subject in the Fine Arts other than Architecture. Designs made during the course of study and measured drawings of a building approved by the Professor of Architecture have to be presented and are taken into account by the examiners.

An excellent point in the scheme for the Liverpool University degree of Bachelor of Architecture is that after the second examination has been passed the student is required to spend two years in the office of a practising architect, or in such other form of practical work as may be recognised, as well as to attend during that time courses of instruction and to prepare certain designs and measured drawings. After this two years' course of practical experience comes the Final examination and the attainment of graduate rank.



As with other institutions, Liverpool University recognises that not all architectural students aspire to the honour of a degree, and it therefore offers as an alternative a diploma course, which chiefly differs from the degree course in the omission of matriculation and of the Intermediate examination—that is, of the subjects of more general education—whilst it retains the curriculum of the second, third, fourth and fifth years of the degree student, including the practical work in an architect's office.

Such is the general scheme of architectural education propounded at Liverpool University for the proper and systematic training of a young architect. We now come to a consideration of the methods by which this training is effected.



The School of Architecture at Liverpool University is the foremost, if not the only, exponent in England of the methods of the Ecole des Beaux-Arts at Paris. Academic classicality in design, the study of the grand manner, is commenced with the tyro's first attack on the "orders." These are drawn not, as is usually the case, as isolated and imperfectly understood examples of columns and entablatures, but as component parts of an architectural design, which itself is regarded as an incident in a composition with its natural surroundings. Thus a large view of architecture is impressed upon the young architect at an early stage of his career, and he comes to regard his art with enthusiasm as something with possibilities and worthy of his best efforts and most earnest devotion. This is surely an excellent groundwork for an architect's training.

In the teaching of design, following the French manner, subjects of an academic, if somewhat unpractical and impossible, character are set for second and third year students; but with the view of preventing the young architect from becoming a mere visionary these idealist exercises are alternated with subjects of a more practical and everyday character in which the construction on modern methods is an integral part of the work. It is interesting to notice that in these designs classical feeling is expressed and classical detail employed, so that we may regard the Liverpool School of Architecture as being essentially classical in its tendency. The Parisian methods of architectural study are so far followed as to embrace their particular form of draughtsmanship with its careful projection of shadows, as may be seen in the blocks we include with our text, and in an example of the work of one of the students, Mr. H. A. Dod, which we include amongst our illustrations in this issue. The examination designs, of which this is an instance, are by the way produced, as in the Ecole des Beaux-Arts, *en loge*, each student working in a separate room.

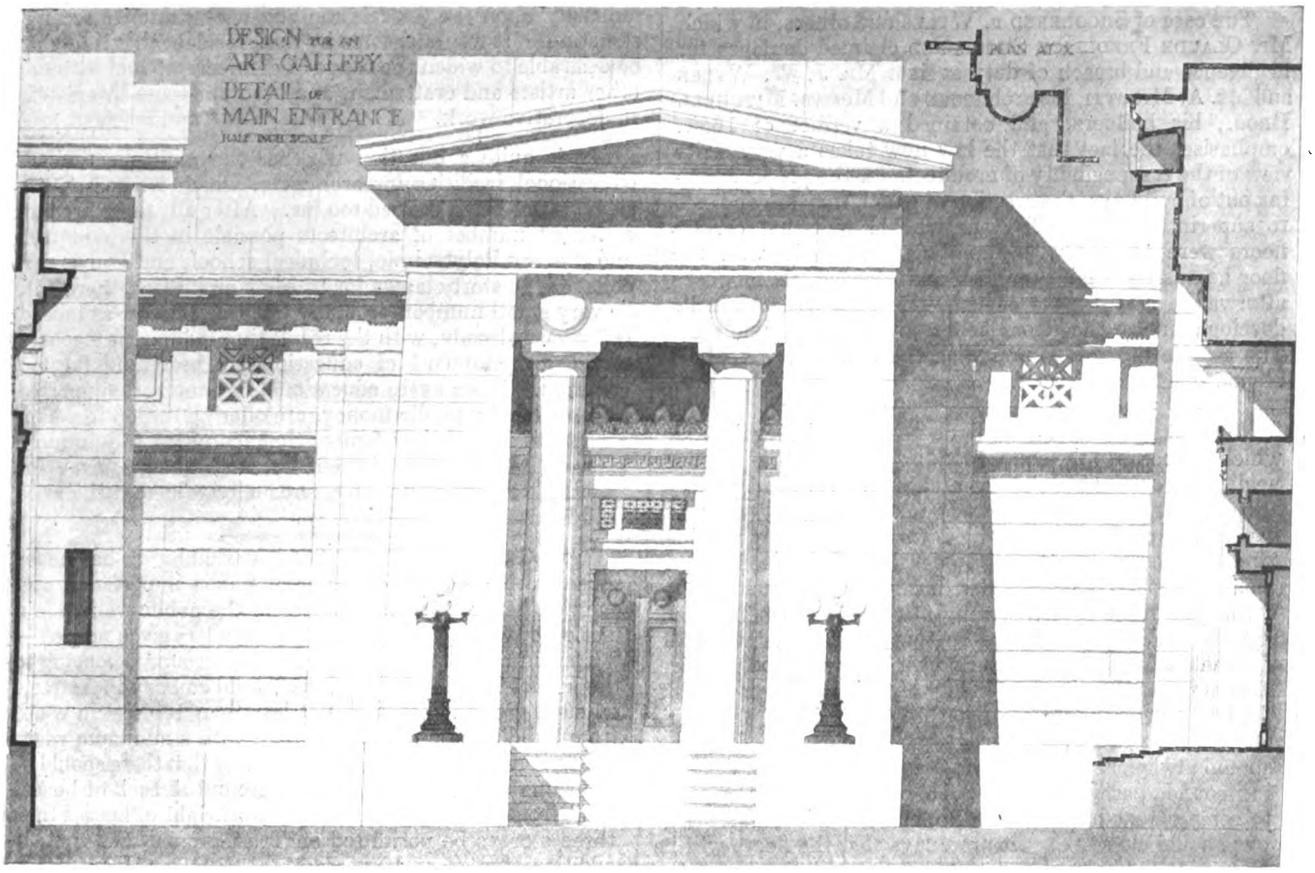
DESIGNS FOR A VILLA

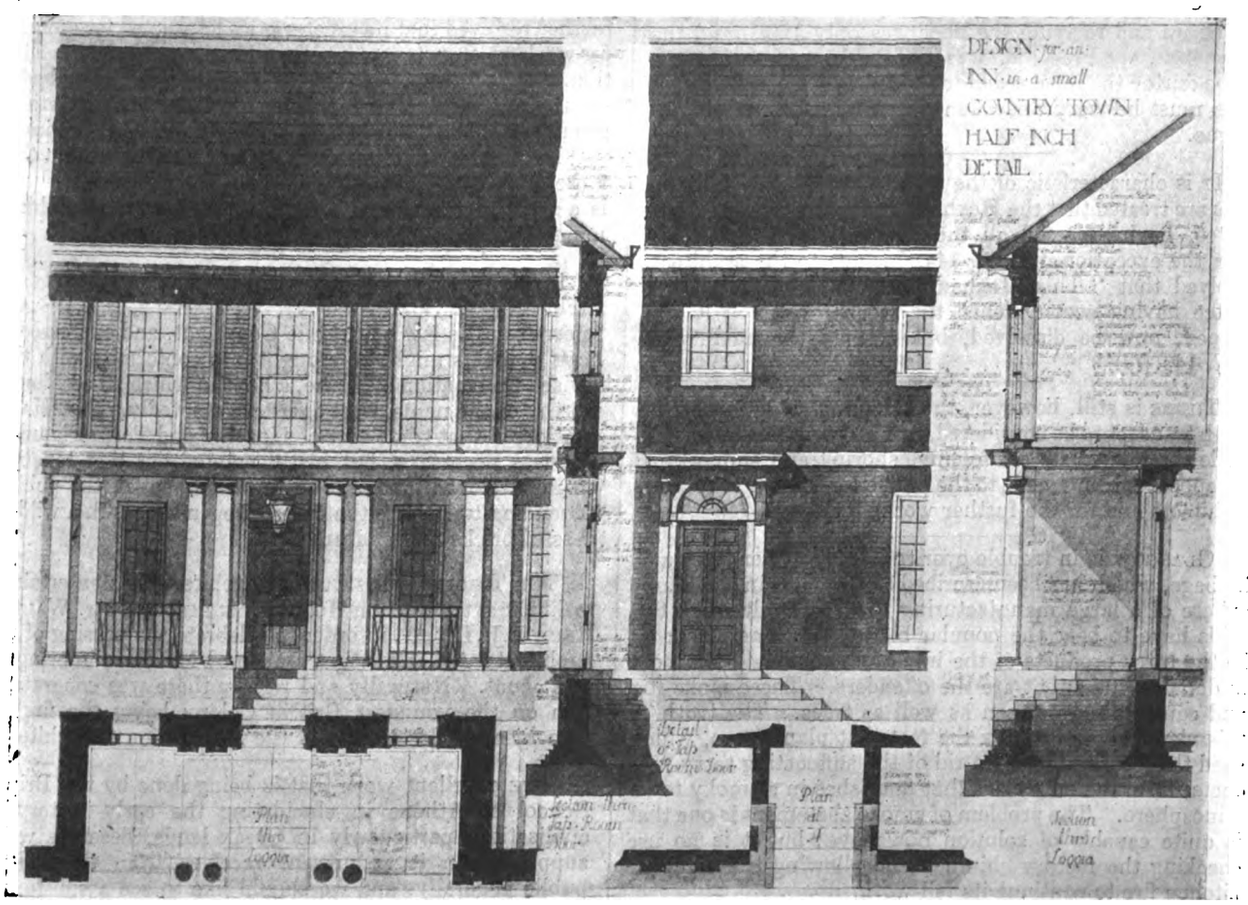
FOR A MAN

OF CLASSICAL TASTE.

Although, as is right, design occupies the first place in the training of an architectural student at Liverpool University, it must not be supposed that other necessary branches are forgotten. History, materials and construction, modelling, drawing, perspective and sciography, graphic statics, all form part of the work of the school, in addition to those subjects taken in common with students of the faculties of arts, science, and engineering.



The fee for the complete course is 30*l.* per annum whilst working entirely in the school, and 2*l.* per annum for the period that a student is working in an architect's office. The fees are also arranged sectionally, so that any student who does not desire the complete course can attend part only. This particularly applies to those who wish to join evening classes, but is applicable also to the day instruction.



The advantages of University life accrue to the architectural student at Liverpool. He comes in contact with students for other professions and callings in athletics and other spheres of social life. Thus not only is his mind broadened and his outlook of life enlarged, but he makes friendships that are of value in after life. He gains, in fact, many of the advantages of Oxford or Cambridge whilst pursuing studies more immediately connected with his future profession than are possible at the older seats of learning. Scholarships and prizes are open to students of the school, and it is satisfactory to note that in the annual competitions of the Royal Institute, students of the Liverpool School of Architecture have already made their mark.

A new development in education is this month started at Liverpool University as a branch of the School of Architecture in the department of Civic Design, of which Mr. S. D. Adshead, F.R.I.B.A., has been appointed Professor. This will provide a training for the class of professional advisers and designers undoubtedly necessary when the present Town-Planning Bill becomes law and in the present recognition of town planning as a subject of importance to the welfare of the community.

That civic design embraces far more than a haphazard laying out of building estates, with the one aim of providing the maximum of frontage for ground rents on any given piece of land, is evident from the curriculum deemed necessary at Liverpool University, and

Digitized by Google

from the staff engaged for the purpose of carrying out that curriculum.

Landscape design will be taught by Mr. T. H. Mawson, civic engineering by Professors J. A. Brodie and S. W. Perrott, civic hygiene by Professor Dr. E. W. Hope, civic law by Mr. H. Chaloner Dowdall.

The high-minded tone in which architecture is regarded at Liverpool University gives promise that the highest aspect of all architecture, civic design, will be adequately treated in the Liverpool School of Architecture.

NOTES AND COMMENTS.

The case of Shoolbred *v.* Wyles and others, in which Mr. Claude Frederick Shoolbred claimed damages for negligence and breach of duty against Mr. J. W. Wyles and Mr. A. Migotti, his architects, and Messrs. Mitchell Bros., his builders, and obtained a verdict of 165*l.*, emphasises the fact that the law now takes a very strict view of the responsibility of architects for the proper carrying out of buildings, the erection of which they are engaged to superintend. Briefly, the trouble was that certain floors were pugged with lime-pugging put in wet, the floor boards were laid, tongued and grooved, three weeks afterwards, and dry rot ensued, no doubt assisted in its development by the floors being covered with linoleum. The architects, in common with the builders, were held responsible for the dry rot.

Dry rot seems to be a regular bête noir to the legal mind, which has come to the conclusion that it necessarily implies negligence on the part of the architect. As nearly every scrap of fir timber that comes to this country may be expected to carry germs of the dry rot fungus only waiting for a favourable opportunity to develope, it is clear that if architects are to escape being mulcted they must see to it that the most thorough precautions are taken to avoid trouble. It is too much the custom to omit air-bricks for the ventilation of upper floors, but it is a very good practice always to put them in, and plenty of them. Never mind if the builder and his foreman do think one a bit of a faddist. Of course it was a mistake to use the pugging wet. Pugging should always be laid dry. It is more effective in deadening sound, permits a certain amount of ventilation, and to some extent hinders the development of dry rot. But one should always expect nowadays that the floors will be covered with linoleum and provide for ventilation below the floor boards and not through them. In this particular case the damages seem to us to be vindictive, as the cost of taking up and relaying the floor was only 120*l.*, and the other 45*l.*, we presume, was for the loss of use of the house during the repairs and for moral damage. So architects must be wary and shun dry rot as they would the plague.

It is characteristic of the way in which church architects are treated that the Hexham Abbey Completion Committee, having passed all the accounts, and paid them with the exception of 580*l.* 14*s.* 7*d.* due to the architect, resolved that "This Hexham Abbey Completion Committee having accomplished the work for which it was formed, now be dissolved, but accepts the liability of 580*l.* 14*s.* 7*d.*"

There is still, however, the alarming condition of the north transept to be considered, and preparations have been made for immediate scaffolding, shoring and supporting. An appeal is being made to the public for 3,200*l.* to pay the architects and for the further works required.

Glasgow is in trouble over the decay of her trees and herbage, which has been ascribed to the acids in the atmosphere of a large manufacturing town; but although the acids have to bear the popular blame, it seems rather to be the tarry products of the imperfect combustion of coal in domestic fires that are the offenders. These make fog and cause injury to men as well as trees. The truth of this view is borne out by the fact that plane trees, which shed their bark and so get rid of the suffocating tarry products, form the only class that flourishes in a smoky town atmosphere. The problem of smoke abatement is one that is quite capable of solution nowadays; but it is no use checking the factory chimney and allowing the domestic kitchen fire to continue its fell work.

At the annual general meeting of the Architectural Association of Ireland, held last week, the President, Mr. George Beckett, M.R.I.A.I., in his inaugural address alluded to some discouraging conditions affecting the Society. Not only is there a slightly diminished membership, but the foundation of a Chair of Architecture by the Senate of the University will, it is feared, operate prejudicially upon the Association and necessitate its reconstruction. It was suggested by the President that it might be desirable to widen the range of membership and include other artists and craftsmen, and even amateurs interested in decorative work.

It is quite a question whether the multiplication of educational facilities for architects, which we see on all sides, is not being carried too far. After all, there are but a limited number of architects possible in this country, and if every Polytechnic, technical school, and University college is to start classes for training architects, there will be very small numbers in many of those classes, as indeed is the case already, with the result that indifferent teachers and a low standard of education are becoming far too common. Then again educational institutions, supported more or less by public money, are offering tuition to young architects at such low figures that many try to join more classes than they can benefit by, and what is given for nothing, or next to nothing, is usually valued at the price paid for it.

The George Heriot's Trust in Edinburgh has under consideration a question of great public importance, and one that betokens a high regard for the public welfare in a motion of which Councillor Leishman has given notice:—"That in all future feus and sales of ground belonging to the Heriot Trust the conditions should embody that streets on such ground should be not less than 100 feet in width from building line to building line, with a minimum width of carriage and footway of 80 feet, and that there should be the same amount of unbuilt-on ground at back of houses as at front; further, that no greater height of houses than three storeys be permitted on Trust ground, and that, in addition, for every 10 acres feued there should be left in each particular district at least one acre for public ground to be used as a recreation ground for public use. It is further resolved that no greater price be exacted for ground for working-class tenements than for villas. It is, in addition, resolved that conditions of feu or sale should embody restrictions against subdividing houses and creating ground annuals." It is hardly likely that such a proposal will be accepted without much discussion, if at all; but the mere acceptance of the notice of motion shows that there is a feeling abroad that town planning means something more than mere money making.

In his presidential address to the Sheffield Society of Architects and Surveyors, Mr. W. J. Hale, F.R.I.B.A., referred to the law of Artistic Copyright, and expressed a hope that this might be brought into conformity with the revised Convention of Berne, a hope in which all architects worthy of the name must share unreservedly. Mr. Hale considered that some sort of Housing and Town Planning Act was necessary, but justly pointed out that taxation on undeveloped land was to the detriment of the public, as tending to remove the oases of open spaces in a wilderness of bricks and mortar.

The Transvaal Institute of Architects has entertained to dinner at the Carlton Hotel, Johannesburg, Mr. Walter Reid, F.R.I.B.A., in order to celebrate the passing of the Architects' Act and the part taken by Mr. Reid in bringing this about. Naturally and rightly there was congratulation on the youngest British Colony being the first to recognise the desirability of the registration of architects.

The excellent work that is being done by the British School at Athens in elucidating the early history of civilisation, particularly in Greek lands, deserves wider support than it at present receives from the British public generally, and we should like to see a substantial diminution of the excess of expenditure over receipts, amounting for the past year to 289*l.* 7*s.* 1*d.* In exploration work particularly it is impossible to always cut one's coat according to the cloth. Early expenditure in excavation may be entirely wasted by shutting down for the want of the last 100*l.* just as the investigators are reaching the fruition of their labours.

Digitized by Google

Curious finds often come before architects in dealing with old buildings, and in carrying out repairs at Tichborne Church, Hants., Mr. N. C. H. Nisbett, A.R.I.B.A., came across a copper disc about the size of a crown piece, with upon it a pointed shield enamelled with an heraldic device, *Or* or *gules* (the colour seems not quite certain), a lion rampant proper (?). Mr. Reginald Smith, of the British Museum, considers the disc to be the decoration of a coffin, probably of fourteenth-century date.

An interesting article appears in the *Antiquary* for the present month on the Romano-British buildings at Stroud, near Petersfield, Hants, by A. Moray Williams, B.A., which with other south country examples illustrates what, for want of a better name, is now known as the "farmhouse" type of Romano-British building, and is to be carefully distinguished from the "villa," under which it has been too usual in the past to include all remains of residential buildings not clearly military.

THE SOCIETY OF ARCHITECTS.

The annual general meeting of the Society was held on Thursday evening, the 14th inst., at Staple Inn Buildings, Mr. George E. Bond (President) in the chair.

The President announced that a students' social evening would be held on November 8 at St. Bride's Institute, together with an exhibition of students' sketches prepared during the year.

The following gentlemen were elected members:—Messrs. Charles W. Ball, H. W. Burton, W. Dingwall, B. E. Evans, O. B. Hatchard, C. H. Heathcote, and R. Morley.

Colonel F. S. Leslie, R.E. (Hon. Secretary), read the Twenty-fifth Annual Report of the Council.

The President said he had very great pleasure in proposing the adoption of the report, and he was sure the members would consider it satisfactory—possibly the most satisfactory the Society had ever had to present.

Mr. G. A. T. Middleton seconded the motion, and said the report was particularly favourable, insomuch as the Council were able to show an increased surplus in their balance sheet when there had been great depression in the architectural profession, and especially as one of the architectural bodies had had to face a continually decreasing balance due to the present bad times.

The report was unanimously adopted.

Mr. E. W. Harvey Piper read the Scrutineers' Report for the election of officers and members of Council for the year 1909-10.

The results were as follows:—

President.—George E. Bond, J.P., Rochester.

Vice-Presidents.—J. W. Dyson, Newcastle-upon-Tyne; Percy B. Tubbs, F.R.I.B.A., London.

Honorary Secretary.—Colonel F. S. Leslie, R.E. (Past Vice-President), Woolwich.

Honorary Treasurer. — Henry Adams, M.Inst.C.E., London.

Honorary Librarian.—C. H. Mead, M.R. San. Inst., London.

Council.—R. George Bare (Past Hon. Librarian), London; G. A. Birkenhead, Cardiff; B. D. Cancellor, Winchester; T. R. Clemence, Guildford; R. Cecil Davies, Chester; R. A. Jack, London; Cholton James, F.R.I.B.A. (Past Vice-President), Cardiff; E. M. Leest, J.P., Devonport; H. W. Matthews, Bath; G. A. T. Middleton, A.R.I.B.A. (Past Vice-President), London; E. C. P. Monson, F.R.I.B.A., London; A. J. Murgatroyd, Manchester; Thomas Overbury, Cheltenham; E. J. Partridge, F.S.I., Richmond; J. H. Pearson, London; E. J. Sadgrove, F.R.I.B.A., London; B. R. Tucker, M.R. San. Inst. (Past Hon. Treasurer), London; R. Willock, F.R.I.B.A., London.

The President returned thanks for his re-election to the chair and the continued confidence of the members.

Colonel Leslie, referring to his election to the hon. secretaryship, said it would be difficult to follow a man like Mr. Ellis Marsland, and he hoped that when the latter had had a year's rest they would be able to have him back again in office.

Votes of thanks were passed to the retiring members of Council, the scrutineers (Mr. E. W. Harvey Piper and Mr. Sidney Marsland), and to Mr. C. McArthur (the Secretary) and the members of his staff. The meeting then terminated.

PANELS IN THE CATHEDRAL OF TORCELLO.

In Italy, within churches whose exterior aspects are plain and unattractive, may be found exquisite work of the sculptor or painter. The exterior of the cathedral at Torcello does not give promise of the rich sculpture within, of which the two panels represented are remarkable examples. These panels form part of the west side of the low dividing wall of the choir portion of the church, and are, therefore, so placed as to be readily seen. They attract attention partly because they are ornamental, partly because of the subjects which they represent. They date from a period (1008 A.D.) when sculptors delighted in intricate patterns which led the observer to try and thread the maze of lines. Even what is representative, in a greater or less degree, of real things, and not mere pattern-making, is made to conform in some cases to decorative effect, as when beak-head forms are reiterated round an arch. In one of the panels (Fig. 1) the branches

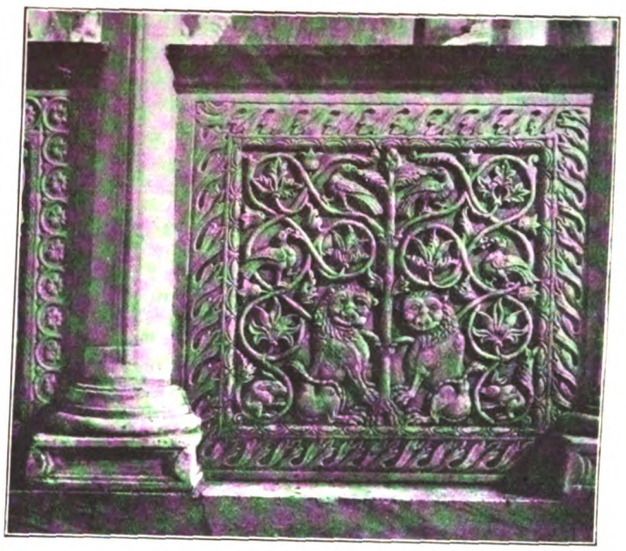

Fig. 1.—PANEL FROM SCREEN, TORCELLO CATHEDRAL.

of the trees assume forms which are too regular and too curvilinear to be realistic, and the tails of the lions are in pattern-form. The ornamentation on one side of the panel so nearly balances that on the other as to lead to the supposition that the variation in the expression of the two lions is a matter of chance. Their eyes, nostrils, and mouths are made by drill-holes, which are also a means towards attaining the rich effect in the foliage of the tree. The tree takes its root from the middle of the bottom of the square, and spreads over nearly the whole of the panel, forming openings for foliage, doves, and, in two cornices, for hares. Six of the smaller openings are filled by calices. The border is composed of a recurring foliage-pattern, the continuity being lost at each corner. It may be supposed that the lions were intended to be formidable and in contrast to the timid hares. Lions in pairs are frequently found at the entrances to churches in Italy, and they may in this position be generally taken to represent sentinels or guardians. It was said of the lion that he slept with open eyes, and Peter Valerian, amid the many meanings which he thinks may be assigned to the lion, includes that of vigilance and guardianship. He says of the lion, "Somni parcissimus est, oculosque habet inter dormiendum splendescentes ac quodammodo patefactos." In the sense of guardians are to be interpreted the lions of the gate of Mycenæ. The grouping, therefore, of two lions to represent guardianship goes back long before the Christian era. Although the position of the lions may be an imitation of representations in which the idea was of guardianship, such an idea is not very appropriate here, for although the panels are in the screen-wall of the choir, yet from Fig. 2 it will be seen that the peacock panel is nearer the entrance.

With Christianity many and varied symbolisms became attached to the lion, and in the absence of some indication from position and surroundings there is an "embarras de richesse" of possible meanings. It may be that in these panels the lions are symbolical of the Resurrection, and as the peacocks have the same symbolisation there is more possibility that they were both selected as representing the same idea, though for different reasons, the peacock because it renews its plumage, the lion because it was said to be born

Digitized by Google

dead and aroused to life after three days by the roaring and breathing of its male parent. It does not, however, appear by any means certain that sculptors of this period associated their different subjects in a very reasoned way. They may,

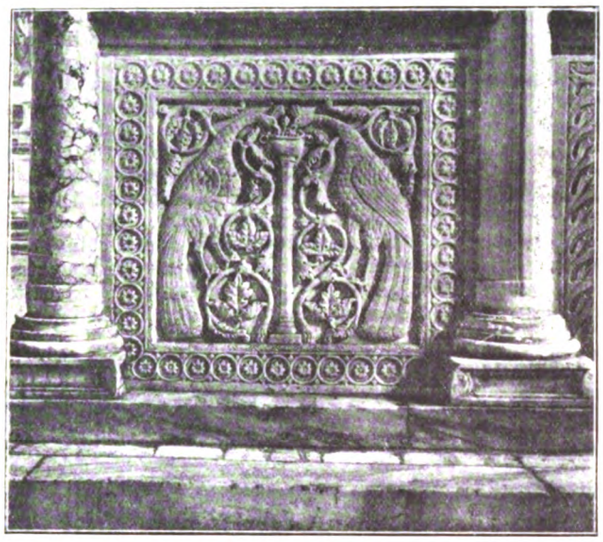

Fig. 2.—PANEL FROM SCREEN, TORCELLO CATHEDRAL.

in many cases, have regarded decorative effect first. At any rate, it is not easy to account for all subjects in the same way, as in the majority of cases lions at the portals of churches and peacocks on tombs may be explained. The sculptor of these panels has, in any case, produced remarkable works. Although marble was his material, he has known how to use his tools so as to produce magic effects of light and shade.

BRITISH SCHOOL AT ATHENS.

PROFESSOR GILBERT MURRAY presided on Tuesday over the annual meeting of subscribers to the British School at Athens, held at Burlington House.

The managing committee in their report state with regard to the excavations that the sanctuary of Artemis Orthia has now been finished, the Menelaëum has been excavated, and the more promising parts of the site of the ancient city examined by a series of trial-pits, with the result that it seems hardly likely that any site of importance remains for future excavation. A large trench was made in the theatre from the top of the auditorium to the orchestra, and it appears that the building is very much destroyed. In the lower parts the depth of earth is very great and houses have been built at a higher level, a process which has probably left very little of the theatre remaining.

Sanctuary of Artemis Orthia.—The additions made to our knowledge by this last year's campaign are best seen by comparing the latest plan with the plan published a year ago. The walls of the sacred enclosure at different periods have been found in great part, especially behind the temple and to the east of the altar. An investigation of the lower strata has shown that the archaic altar and primitive temple are later than the cobble pavement with which the hieron was paved, and the walls of the hieron at this early period have now been found. This gives an earlier stage of the sanctuary than had before been clearly made out. In this earliest stage the precinct was smaller than in subsequent periods and the centre of the cult nearer to the centre of the hollow in which the sanctuary stood. This is shown by the position occupied by the deposit of black sacrificial ashes. At this stage there seems to have been no temple, but there are remains of what was probably the altar. The first stage of all is represented by the ashes and geometric pottery found below the cobble pavement. In order to carry through this work a further small portion of the foundations of the Roman amphitheatre was removed.

In the first year of the work part of a large subterranean water-channel was discovered, and this has now been fully excavated. It dates probably from the fourth century B.C., and was broken into and largely destroyed by the building of the Roman amphitheatre. Solidly built of dressed stones and roofed with large slabs, it is a remarkable work, and very probably was constructed to carry off the water of a natural brook that in early times may have flowed down to the Eurotas through the hollow in which the sanctuary lay.

The archaic deposits proved to have been nearly exhausted in previous campaigns. Some important objects were, however found, notably an ivory plaque representing the winged Orthia with a bird and a snake. This absence of finds from the outlying parts of the site satisfactorily proves that the whole sanctuary has now been exhausted and the full harvest reaped. The final publication of the objects found has still to be undertaken.

The Menelaëum.—In May we were led to excavate the building which has been for long identified with the Menelaëum. This building stands on a hill overlooking the east bank of the Eurotas, with a commanding view of the site of Sparta. The result is a plan differing materially from the sketch plan published by M. Kastriotis, who had already excavated the site. The building now reveals itself as an oblong platform which may have supported a small temple or other monument. This platform stood upon another, from which it was reached by a ramp, the traces of which are preserved. To this structure a terrace was added later on two sides. The date may be the fifth century.

An interesting series of bronzes, notably an archaic figure of a woman, terra-cottas and lead figurines were found. The pottery was especially interesting as filling up a period (Laconian II.) which is not well represented in the series from the Orthia sanctuary. The majority of these finds were made on the slope below the building in a position which showed that they had been thrown out from it. Some of these certainly belonged to a period earlier than the present building, and some blocks were found which probably formed part of an antecedent structure.

Below all the other finds some undoubtedly Mycenaean sherds were discovered, and some Mycenaean houses, as yet only partially examined, were found a short distance away. This Mycenaean settlement will form the subject of future work.

N. Greece.—The subsidiary excavations carried on last year in N. Greece by Messrs. Wace, Droop and Thompson have been resumed.

These excavations are designed to throw light on the early civilisation of N. Greece. Two sites were selected for this season's work—Palaeomylos, near Lianokladi, in the Spercheios Valley; and Tzani Maghoula, near Sophades, in W. Thessaly. At Lianokladi the excavators were at once successful by sinking deep shafts across the mound to the level of the virgin soil. They found three well-marked strata, in the lowest of which were sherds of the "red and white" ware akin to, though of finer style than, that which has been found in Thessaly and Phocis.

In the stratum above this the pottery changes completely and is of the "black lustre" style similar to that found at Orchomenos by Dr. Furtwängler. The pottery of the third and topmost stratum was of a type hitherto unknown, a reddish-brown hand-made ware with black geometric patterning, which the excavators are disposed to regard as contemporaneous with late Minoan III.

At Tzani Maghoula, as at Zerelia last year, no less than eight successive settlements were excavated. The stratification here is particularly good and will make it possible to correlate this with the other prehistoric sites of N. Greece. Among the more important finds were two or three nearly complete "red on white" vases from Settlement VII., and a fine collection of bone pins.

Rhitsóna.—The excavations at Rhitsóna, in Boeotia, were continued by Professor Burrows from March 29 to April 17, with the help of a grant from the University of Manchester. His primary object was to obtain further light on certain problems raised by the first season's work, and he excavated with special attention to the bone remains. He was fortunate in receiving a visit from Mr. C. H. Hawes during the excavations, and in securing his services later for a detailed examination of the bones in the Thebes Museum. Of the twenty early graves excavated, a large number contained undoubtedly single interments, and thus support the view maintained by Professor Burrows and Mr. Ure in *B. S. A.* xiv., that this was the normal practice at Rhitsóna. Their theory as to the late date of what they have called the Boeotian Kylix style is also supported by a number of tombs now found that contain proto-Corinthian or good Corinthian, but no Boeotian kylikes. The number of vases excavated was, as before, very large. Among individual finds may be mentioned some Corinthian Black Figure or "Rottonige," the first found on the site, and an interesting stone sarcophagus, conveyed entire to the Museum at Thebes,

Digitized by Google

containing a complete skeleton, proto-Corinthian vases, and iron fibulæ.

Professor Gilbert Murray, in returning thanks for having been invited to occupy the chair, said he was particularly glad of the honour because it was a recognition of the essential unity of Greek studies when one who was almost entirely a literary scholar was invited to address archæologists. The time had passed when literary scholars could afford to speak slightingly of archæologists, and when archæologists were goaded into a reciprocal contempt for scholarship. It had come to be recognised that the whole of Greek life and thought was too vast a subject for one man to master, and also that every single department of it was dependent on every other. Professor Murray said in his own work he could hardly move a step without referring to archæologists.

If the work done for Greek studies by the School of Athens could be summed up in a single phrase, it would be that it made them real. It takes new men every year to the soil of Greece, it lets them handle the actual stones of the Parthenon and the Erechtheum, and study the actual marks of a fifth-century chisel, and learn much else that could never be found in a book. It had, apart from the positive discoveries, effected a change in the quality of our knowledge. The discovery of concrete objects at every turn has permeated the whole study of Greek and made that concrete also.

Much was to be said in favour of a classical education. It involved the study, first, of language (one of the richest and most educative subjects possible), and, secondly, of a particular period of human history. In the case of Greek that period was one in which life was not only extraordinarily interesting and progressive, but also to a great extent, compared with later times, undifferentiated. Whoever has studied well that one moment in the life of mankind will use more of his mind and have obtained an introduction into more phases of human thought than anyone beforehand would have thought possible. That classical education has in the past sometimes failed is chiefly owing to three causes, viz., lack of variety, lack of concreteness, and lack of progress and discovery. The remedy for this was to be found in the work of the British School.

The present condition of classical studies in England was encouraging, for the standard was never so high, and it was doubtful if there were ever so many individuals who knew Greek. This optimism was felt despite the loss of the educational monopoly. There were abundant signs that Greek was a flourishing and not a decaying study. At no time were the masterpieces of Greek art so well known as at present, and often not merely known by sight, but intelligently and lovingly studied. People in most unexpected callings and places seek advice as to learning the language. A company in New York is wanting to act Greek plays, not merely for edification but for commercial purposes. Certain semi-philanthropists who wish to act poetical plays in the slums have decided to commence with a Greek tragedy. In another case a railway servant and his wife wrote for advice about learning enough Greek to read Plato. They had already learnt sufficient to read the New Testament by means of a weekly newspaper which gives every week a bit of Greek grammar and a reading lesson. Such students as these two would be more valuable than twenty reluctant public schoolboys forced and cajoled through Pass Mods. The monopoly of classical education has certainly been lost through the abolition of compulsory Greek. But now a much larger possible field has been thrown open.

The whole of Hellenic study is organically inter-connected, and the man who collates MSS. of Homer, who sifts and analyses tons of Thessalian earth to collect and date a lot of broken pots and figurines—most of them ugly—who teaches a bit of Greek grammar so that it is understood and remembered, all alike and together are serving in the common task and helping to keep alive an ideal which the world must never be allowed to forget, the great complex of noble imagination, keen sensitiveness to beauty, of hard thinking and strenuous endeavour which bears the name of Hellenism.

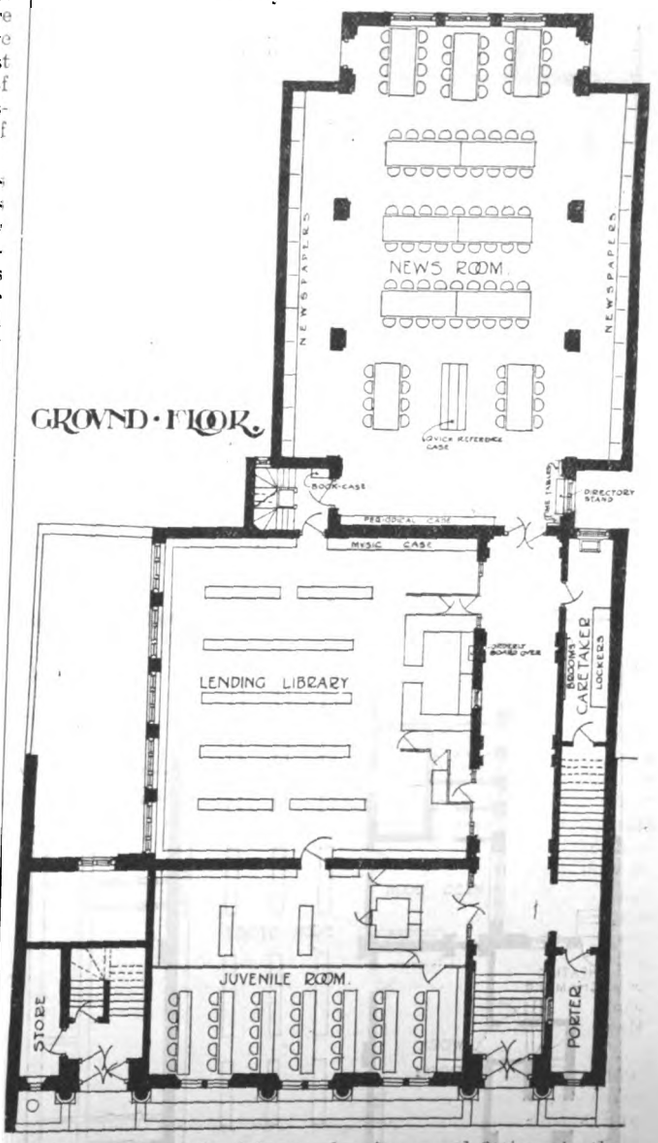
The proposal of Professor Murray to adopt the annual report was seconded by Mr. H. H. Statham, F.R.I.B.A.

Mr. R. M. Dawkins, the Director, then proceeded to give an account, illustrated with lantern views, of the various excavations carried out by the school during the past year.

Mr. Frank L. Pearson, F.R.I.B.A., has been appointed to advise the Maidstone Urban Council as to the best course to adopt for restoring the west front of the Old Palace.

COMPETITIONS.

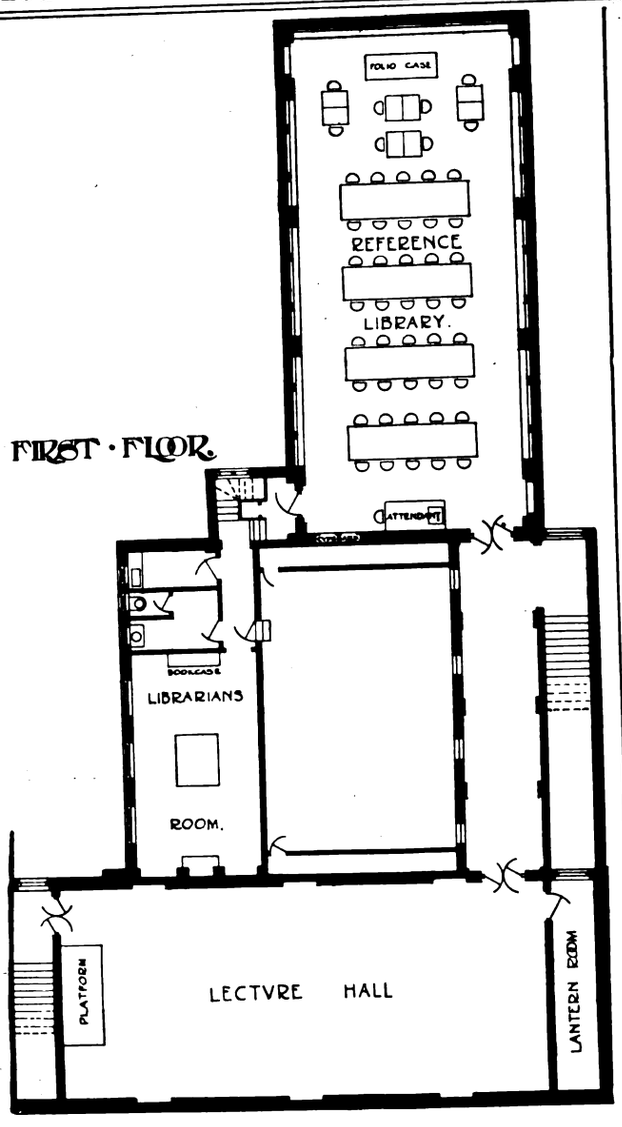
THE Secretary of the Royal Institute of British Architects desires us to announce for the information of architects proposing to take part in the competition for the Warrington elementary school that the R.I.B.A. competitions committee are corresponding with the promoters with a view to the amendment of the conditions of this competition.



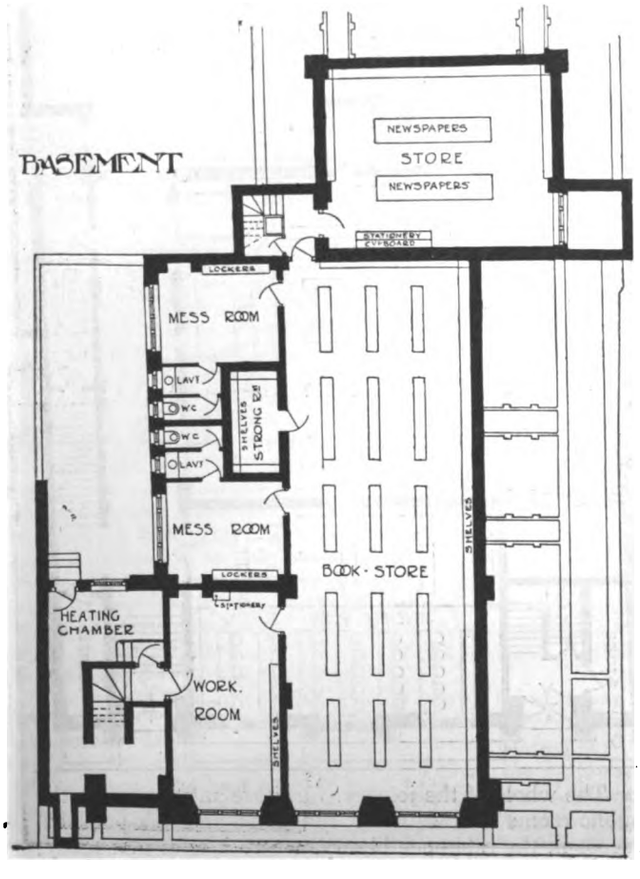
The probable result of this correspondence may be judged from the following:—

At the meeting of the Warrington education committee on Monday night the sites and buildings committee reported that communications had been received from the Royal Institute of British Architects and from architects in reference to the conditions of the architectural competition for the Evelyn Street Council school, but the committee could not see their way to make any alteration in the conditions beyond allowing the return of the deposits to those architects who return the conditions and planning rules.

ILLUSTRATIONS.



FULHAM CENTRAL LIBRARY.



THE site is a somewhat unusual one, being narrow in frontage and of considerable depth. This has necessitated the main entrance being at one side, the newsroom occupying the entire width of site in the rear, and being lighted from the end and by a clerestory along each side. The floors and staircases throughout are of fireproof construction. The front elevation is of small-sized red bricks with Portland stone dressings, and the roofs are covered with Precelly slates.

The whole of the joinery, furniture and fittings in the public rooms is of wainscot, fumigated and wax-polished, except in the reference library, where it is of mahogany,—

Digitized by Google

stained dark and French polished. The floors throughout are covered with linoleum. The heating is by low-pressure hot water, and all rooms are ventilated by an electric fan placed in a central position. Mr. Henry T. Hare, F.R.I.B.A., is the architect.

The general contractors were Messrs. F. & H. F. Higgs. The principal sub-contractors were:—Fireproof floors and steelwork, Messrs. Aston & Son; steel casements, Messrs. Pearse & Co.; heating and ventilation, Messrs. Jeffreys & Co.; electric lighting, Messrs. Higgins & Griffiths; scagliola, Messrs. Bellman, Ivey & Carter; ironmongery, Messrs. Ramsay & Co.; carving and modelled plaster, Mr. L. A. Turner; front railings, Mr. Nelson Dawson.

THE GARDENS AT CHELWOOD VETCHERY.

THIS drawing, which was exhibited in this year's Royal Academy, illustrates a yew-walk or bowling-green lying due north and south, and connecting the park shown in the distance with the gardens. This walk is also intended to divide the kitchen-garden from a proposed triangular scent-garden shown on the right of the drawing. The remainder of the gardens are terraces, croquet-lawn, lower terrace with lily-tanks and water-channel, tennis-lawn and a "bosquet," all of which lie in terraces in the order given to the south-west of the house, and are linked up on the south-east side by a wide grass path bordered with wide flower-borders. The yew-walk also connects with this grass path.

The garden has been cut entirely out of a wood, interesting as surrounding the site of a hunting-lodge of John of Gaunt. The soil was for the most part very fine sand over sandstone. The retaining walls and steps are of local stone built dry, with the exception of those near the house, which are built in mortar with balustrading, and gate piers of small sand-faced, cherry-red bricks, made locally by the contractor, Mr. Job Luxford, of Forest Row. At either end of the house are a sunk garden and a rose-garden, the latter having brick-paved paths and being screened by a high oak trellis between brick piers. The gardens were arranged by Mr. L. Rome Guthrie to surround a charming house designed by Mr. William Flockhart, F.R.I.B.A., in the Tudor style.

OXFORD COLLEGE SERIES, BRASENOSE.—SHOWING RATCLIFFE CAMERA AND ST. MARY'S SPIRE—LIBRARY.

IN our issue of October 1 we gave a descriptive account, by Mr. John Buchan, of Brasenose College, and in the preceding week we illustrated the college as seen from the High Street and the Chapel Quad.

LIVERPOOL UNIVERSITY SCHOOL OF ARCHITECTURE.—DESIGN FOR ART GALLERY.

THIS drawing is an example of the work done by students at the Liverpool University School of Architecture, and is referred to in our leading article.

The Original Drawings made by Mr. Louis Weirter for Archdeacon Sinclair's "Memorials of St. Paul's" have been purchased by the South Kensington Museum.

The Foundation-stone of St. Martin's Church, Worcester, was laid by the Countess Beauchamp on the 9th inst. The church, which is designed to accommodate 800 adults at a cost of about 10,000*l.*, will be of Worcestershire red stone rock-faced externally, and the interior facing will be of brick, with Box-ground stone dressings. Messrs. J. & A. Brazier, of Bromsgrove, are carrying out the work from the designs of Mr. Geo. H. Fellowes Prynne, F.R.I.B.A., architect, of Westminster.

Messrs. Walker & Ramsay, 123 Wellington Street, Glasgow, have been appointed as architects, and Messrs. Henry Herbertson & Co., 167 St. Vincent Street, Glasgow, as measurers for the Scottish Historical Exhibition, which is to be held next year in Kelvingrove Park. The guarantee fund of the Council is already 75,315*l.*

THE ARCHITECTURAL ASSOCIATION.*

(Concluded from last week.)

THE Water-colour Class, which must surely be a favourite subject with the majority of us, is languishing for lack of support, and is likely to die out like the Modelling Class a few years back. The Life Class, too, has to hunt for members, whereas the room should be really far too small to hold all the applicants; why it is not fully attended it is difficult to imagine. The younger members have their hands already full, but those who have done with the schools surely would do well to turn their attention and part of their spare time to this instructive and delightful branch of art—the study of the figure from life.

I trust, gentlemen, that you will forgive me for this little disquisition on our shortcomings, or what is more important, I hope you will consider it, and that the Architectural Association will profit by it. I do not think there is any value on an occasion like this in looking only on the bright side of things and disregarding those less satisfactory, or else those departments suffering under the shade of adversity would continue to do so while the more favoured, basking in the sunlight of the Architectural Association favour, would continue to flourish like a green bay-tree, whose spreading leaves would only add more to the obscurity in which the others languish.

A propos of the bad times from which most of us are suffering at present, I should like to tell you that the Council is always ready and anxious to help our men to the best of its power, and the desire of the members is to aid rather than harass, as regards paying subscriptions, &c., those who are found to be in straitened circumstances. The register of assistants, too, is now only open to members, and we have been able thereby to find work for more Architectural Association men than before, and I believe that there is a very material benefit derived from the alteration.

It has occurred to some of us that there is not enough social life in the Architectural Association; that we meet so almost entirely in working hours, and consequently so seldom in moments of leisure, that the men of various decades do not get to know one another, and we should like to see more of the men who no longer wish to come here to study, but I suppose that their absence must be ascribed to the natural reaction after the years of hard work. However that may be, we are thinking of flattering the Royal Institute in the sincerest form, *i.e.*, imitation, by copying—on a smaller scale, of course—the "At Homes" which have proved so successful with the senior body. I hope if this can be arranged that the members will give the Council their support, as it is only by the aid of mutual confidence and assistance that a body like the Architectural Association can hope to be successful, and we are now so numerically and geographically extended that it is only at such evenings as I suggest that a large number of our members could or would ever meet; we have in the Museum premises well suited for such entertainment, and this recalls the fact that we have still the Architectural Museum apart from the Architectural Association as an annual charge on us, though it was formerly supported entirely by subscription, and I hope that the public and all interested in architecture will not forget this, as we seem in danger of not being able to maintain our list of subscribers, new ones not coming forward to fill the gaps unfortunately caused by the loss of former members, in which connexion we have to deplore the death of such men as Lord Ripon and the Hon. Dudley Fortescue. The collection of casts which we possess will bear comparison with any in the country, and we have spent a large amount on the Royal Architectural Museum in order to get it properly housed and arranged, in the hope that it would prove more useful to all students of the many styles of work which are represented in it.

Of the many branches of the Architectural Association, the educational is, of course, the most important, in fact the whole organisation is being run more and more with this department in view as the main object. Since our school was started more have sprung up in every direction, and I see that one is now being started in Birmingham, and when there are enough schools to educate all those seeking an architectural training, which time rapidly approaches, I imagine there will be ample support to the proposition put forward in the papers a short time back, of a diploma course in architecture, and over which there was a great amount of discussion; the different schools naturally shape their studies on varying lines, quot homines, tot sententiæ, and I think it ill becomes any among them to lay down the law as to which is the best; the diploma course would attract the best men from each centre, and the various systems could be compared by results. The proof of the pudding is in the eating, and we, I am sure, have here a very good pudding, though there may be others of a different make more to the liking of the cooks who have had a hand in the mixing.

Our students' exhibition of work this year was a very good one, a general level of excellence being maintained which always speaks well for both masters and students. Mr. Maule, Mr. Varndell, and all the other masters work most conscientiously for the welfare of the students, who in turn must, I am sure, ably second their efforts to produce some of the work we have seen, and I am confident that in our two years of day school study and two of evening school, the students receive a very valuable and sound grounding in their work, which must be most useful to them in after life, and very different to the scrappy and haphazard fragments of architectural pabulum from which the students of even ten years ago extracted what education they could; but there is no doubt that our nourishment could with great advantage be followed up and amplified by the course of higher studies, which cannot be embraced in the short time at our disposal here.

The Camera and Sketching Club is another flourishing department of the Architectural Association, and I think that is largely owing to the energy and administrative power of Mr. Alan Potter, who has devoted a great deal of time and trouble in working up the club, backed up as he must be by a hard-working committee. Their excursions, particularly abroad, seem to me to be wonders of comprehensiveness, and of great value to the younger members, as they are, I believe, run on the cheapest methods and on bicycles. The latter method of locomotion does not perhaps recommend itself very strongly to some of us who prefer the comparatively luxurious and very complete methods of transport arranged on the Architectural Association annual excursion by our excellent Hon. Secretaries, Brown and Hennings. I do not intend to intimate that the excursion is run for the older men only; far from it, we welcome gladly new and young men, and I can guarantee this, and I feel sure those who have experienced it will agree with me, that no one is ever allowed to feel lonely or apart—all are friends, and our efforts are directed to making all enjoy themselves, which is none the less possible because we have a very full week and get through a lot of work.

The photographic work of the Camera Club is becoming increasingly useful to the Architectural Association; the collection of slides, now numbering 4,000, contains examples of almost every style of architecture, and is of the utmost value to lecturers and readers of papers, and I venture to think there are very few subjects connected with our profession which could not be illustrated, to some extent, from the collection.

Our Athletic Club numbers over 200 members, an increase of fifty during the last year, and I am very glad to see it in such a flourishing condition, as personally I take a great interest in athletics, and the club is one which exercises a powerful influence for good in every one of its members. Sport improves every man's character, and teaches him to lose well, as also to win well, and the title of a "good sportsman" is one that every Englishman covets, for it does not only refer to the athletics we indulge in, but to our efforts in the serious game of life; a healthy mind flourishes best in a well-developed body, and physical fitness is the best aid to good work, and the record of the athletic men in the schools here is no exception to the general rule.

The sports annual meeting is one which I should like to see better attended, and one which Mr. J. H. Squire even suggests might be made an official summer reception, and I hope next year we shall get a better attendance, although on the last occasion those who were present made up, as far as is possible, by their enthusiasm for the numerical failure. The rifle section, which supplies the largest contingent, encourages Imperialism in a practical form by supplying a good number of Territorials to our home defence, for which reason alone every one who is in a position to do so should subscribe to it. The Rugby football section is one of which we have reason to be proud, as the record for this year shows a very high percentage of wins; and if sufficient support is forthcoming—and I have already several names—I hope to start a golf section this winter, and as the game has now become so popular, I trust we shall have no difficulty in getting together as good a side as in all the other athletic branches.

It would not be possible to review the various subsections of the Architectural Association without mentioning the Musical Society and its worthy Hon. Secretary, Mr. P. W.

* President's address at the opening meeting of the Session on October 8 last.

Lovell; it is a body which caters largely and frequently for our entertainment, and incidentally I may say I should like to see more supporters of this deserving section. It is not necessary to be a musician to join—that is not within the power of many of us, but it seems very hard that men who work so well should also have to pay out over the play when the performance is given for the benefit of the community. The last play unfortunately did not pay its way, and the burden of the debt lies heavy upon us, so that any subscription towards the deficit would be very welcome, as it is only by this means that the debt can be wiped out.

I am afraid that you will all begin to think that my address to-night savours too much of a charity sermon, or even worse, for on such an occasion you would be asked to loosen your purse-strings for one object only, while I have asked for assistance for many; but remember it is the workers we want in all branches—art, science, and recreation—even more than the subscriptions, and if each of us were to devote some small portion of his time to one only of our various branches we should be in a very satisfactory position.

Among the happenings of general architectural interest during the last year, the Housing and Town Planning Bill is one of which we were led to expect a great deal of good, but the more recent legislation which is being framed with regard to land taxation would seem to have a malevolent influence on the maintenance of open spaces in towns, at any rate, by private people. However, it has been said that religion and politics are the Scylla and Charybdis of public speaking, so I must refrain from enlarging on this subject or I shall be drawn into the whirlpool, but I cannot help saying that it would have been much more satisfactory if the disinterested offer of help from the Institute had been received in better part by the authorities in charge of the Bill, for if there is one thing on which the heads of our profession should be consulted it is surely this, and a good architectural result might then be obtained quite compatible with sound engineering requirements and a satisfactory financial result.

The Patents Act has benefited us to some extent, owing to the factories which now have to be put up here by the foreign owners of patents registered in this country, but on the whole there is a decided tendency just now to leave building alone until some clear idea is obtained as to the final imposts which land will have to carry.

We are to have further legislation by the London County Council under this year's General Powers Bill in which the claims of steel as a reliable building material are properly recognised, and it allows the erection of steel-frame buildings throughout, *i.e.*, instead of the thick outer walls formerly required, we may now have thinner panelled walls with steel framing; but, on the other hand, the internal structure is now to be subjected to further supervision, this part of the building being rightly held to be an integral part of the outer shell, whereas with the brick outer shell such was not the case; but a heavy responsibility is being laid on the London County Council and the district surveyors, as they will be answerable for the stability of the new type of building, and I fear some amount of time must be lost in getting plans approved, and time is a factor on which our clients nowadays never fail to lay the greatest stress, and I must say I am inclined to think that taking the responsibility from the architect is a mistake; it means the work being done twice over and taking a large amount of interest out of our work, as the architect should be the author of the entire building, including the structure.

The strides made in ferro-concrete, which is recognised as a subject of future legislation in this Bill, have been prodigious, and though up till recently this type of construction has been utilised chiefly for engineering work, its influence is now being felt in our architecture, and this opens up a very wide question for consideration, for if this medium is going to be, as I think, the one utilised in our larger architectural works, we shall either have to take up the study of this form of construction with its attendant possibilities, or we shall find there will come into existence a ferro-concrete specialist who will take over the general construction of the building, and the architect will be relegated to the decoration of the interior and the design of the exterior.

This raises a point of supreme importance which we are sometimes inclined to overlook, we must design our work to suit modern conditions. It is impossible to insist on the acceptance by the public of the type of work which was suitable even twenty or thirty years ago; we have to face the problem and accept the present conditions and endeavour to treat them architecturally, instead of attempting to make modern requirements bend the knee to preconceived ideas of architectural treatment, and surely this can be the one way to evolve a style of architecture of our own, which can only be good if suitable to the conditions of the country and the requirements of the people.

I am referring here, of course, to the large commercial buildings in our cities, but in domestic work we have a freer hand, as the habits of life in the home can never change so thoroughly and so quickly as in the world of business. Why should not good architecture be produced with modern materials and to suit modern users? The steel column and beam are accepted facts—why hide them with an arch and a dummy pier? Why should not our construction be shown in our designs instead of being hidden or obscured as much as possible? There is no doubt that we shall have to evolve a new method of treatment for the modern types of construction, unless we are going to be content to let our architecture be a mere shell or screen of stone or whatever material we may elect to use, pegged or hung to the structural members, screening these from view without indicating their underlying form, as should surely be the case.

Architecture, we all know, constitutes an art and a science, and every year we live the latter component asserts itself more forcibly and will not be denied; it is becoming more closely interwoven with the artistic part of our work, and has a very material influence on the result, and we cannot shut our eyes to the fact and attempt to work only for the artistic. We can only produce an unsatisfactory result where we do not boldly tackle the problem with all the attendant difficulties; we cannot elect to deal with any question from the particular point of view which we desire, to the exclusion of the less interesting factors.

No one can fail to be struck by the general improvement in the attitude of the public towards town architecture of late years; planning of streets and open spaces has received so much more consideration, and the relation of individual buildings in connection with streets and adjoining work is not now so consistently disregarded. The average Britisher, to borrow a term from the other side, now takes a broader interest in architecture, and his horizon is not bounded by the particular buildings in which he lives or works; and as he educates himself the book opens, he knows the good from the bad, and begins to appreciate the former, and thereby creates a demand for that which we have to educate ourselves to supply.

With reference to domestic work, we have many men carrying on that high tradition in architecture for which England is justly famous, and I think we may congratulate ourselves in attaining a very high general standard at the present time; the public will not have the house which satisfied them a few years back, so even the speculating builder has to produce houses more consistent with the accepted canons of art than those he formerly flaunted in our architectural faces. In this connection I should advocate the assistance, but not the entire control, of the woman in architecture, for, in spite of the risk of bringing down on my head the wrath of the suffragettes, I feel sure that the wider architectural field is not one for which the woman is particularly adapted, but in domestic work she would be a very valuable ally. How can mere man expect to know the working of a house like a woman? Especially behind the scenes in the arrangement of the service and kitchen department; and very often in decoration we should many of us produce better work if we had the advantage of feminine assistance.

Another bone of contention which I feel bound to touch upon is that of registration. I myself am in favour of it; of course, no scheme of registration can elevate the art of architecture, but it seems to me that it certainly cannot do it any damage, and, incidentally, is sure to eliminate some of the undesirable, and might put us on a better recognised footing; but before we can be better we must be worse in such an all-embracing scheme as it must be to become law. Many self-styled architects must be included in the roll, but that is or should be the end of this class except so far as the public care to trust any unqualified man when they know that qualifications are essential. Before we can get satisfactory registration we must become a united body, and the advocates of the extreme views must moderate them; but one thing is quite certain, the movement cannot be rushed as one party at the moment seem to desire, as no Bill would stand a chance of becoming law if opposed by any considerable section of the same profession as the promoters; but I venture to think that the anti-registrationists are lessening in number, and I feel sure that they, being mostly in the forefront of the profession, will not stand in the way of a movement that so many think would improve our lot, although they themselves have succeeded in spite of the present position of affairs. There is, to my mind, one most essential factor, and that is loyalty to the central body—I

Digitized by Google

mean the Institute. If this point was now generally realised the advantages to the profession would be immense; until nearly, if not all, architects belong to the Institute, the Institute in turn cannot put forward its views as those of the profession at large, and those architects in favour of the movement who refrain from supporting the central body are only weakening the cause of registration, and not advancing it.

There are here to-night a good number of students, some successful in this instance, and some who are going to be. Those who have carried off the awards I congratulate sincerely, but I would urge the others, some non-competitors and unsuccessful ones, to press forward none the less energetically because they cannot just now see their way to the top; remember that you are only on the lower rung of the ladder. Try again, or start to try, if lack of confidence in your own abilities has restrained you hitherto; the competition for the prizes has not been numerically strong of late, and you may find that you can do better than you think, and obtain honours here, to be repeated in the more important competitions at the Institute and again later in the field of life, where you may gain the highest honour of all—the appreciation of your fellow-workers, which nothing but the very best you are capable of will ever obtain for you.

I have often wondered lately if the brilliant draughtsmanship of the day, unless carefully guarded against by the student himself, may not have a derogatory influence on design; a too fluent pen or pencil is liable to run away with the happy possessor, though at times I admit he is wont to rise to far higher flights of fancy than the man less gifted in this way; but the product of the literary man's pen is his finished work, while the drawings of an architect are only means to an end, a step towards the building itself, and what looks well on paper, when drawn as well as some of you can draw, is liable to be misleading and less satisfactory in actual execution; therefore I would say, do not be satisfied with designing on paper without knowing the value in actual concrete form of the lines you put down, and the only way to know this is to take every opportunity of observing in actual work the value of different treatments, groupings or mouldings, and imagine how you would represent them on paper. I feel sure that most of our ideas, in some shape or form, have been thought out before, and in all probability executed, and are waiting somewhere for our approval or the reverse, to give us the advantage of modifying our ideas by the experience of those who have gone before.

The power of observation, when highly cultivated, is of inestimable value to us; a friend of mine remarking on it in this room once said, "I wonder how many of the men here know the number of panels in their front door?" I was the first victim, and for a short time afterwards I went about counting door panels as an exercise. I wonder how many of you are as ignorant as I was?

I noticed recently in one of our periodicals a short article on London as seen from the trams, of which I believe there are about four hundred miles, in which the author remarked what a good knowledge of our city could be obtained in this way, and what a valuable asset that knowledge would be; how true this is, and how little most of us know of this big city in which we live, when you consider that you can now ride on 'bus or tram, from east to west or north to south, over the one hundred and seventeen square miles covered with buildings in the Administrative County; you can imagine what a panorama of architecture and building is spread before you, an open book seldom read through; but study every page, good, bad, and indifferent, sum up and analyse every example before you, find out why a building strikes you as good; is it mass, colour, detail, or some fresh note in composition which has been struck? Consider even the works which do not impress you favourably; there is something good in most of them, or you may, at any rate, learn to avoid some pitfall that has been the undoing of a former essay, and above all, I would say, criticise kindly, look for the good in all and not the bad, hesitate to say to yourself how much better you would have done it. You never know the limitations, the troubles, the laws, the by-laws, the client's requirements with which the man who was responsible was hampered, and whether under similar circumstances your own work would have compared so favourably with it as you are inclined to think.

The difficulties that beset the path in actual practice, especially in large towns, are legion, quite apart from the matter of design, but these special requirements are increasing every day, and they must all be known to us before we can give of our best, for they will probably affect our designs very considerably; but if we strive earnestly to do the best that we can in every case, even though others at first seem too far ahead, in the end the earnest worker always gets his reward. One form of genius has been described as "an infinite capacity for taking pains," and the man of that type is never far from the winning-post at the end of the race.

Mr. Walter Cave, in proposing a vote of thanks to the President for his address, congratulated him on the honour of his election to the chair, which was thoroughly deserved. Few members had been more intimately connected with the working of the Association than Mr. Tanner, and he felt sure that the interests of that body would be furthered and strengthened during his term of office. The address they had heard was a masterly one, but he was struck by the reference in it to the question of finance. They were accustomed to think that the Association was more than paying its way from the fact, perhaps, that they had been able to get into the present building and pay off their debts. It was suggested that serious retrenchments would have to be made in the working expenses and an overhauling of their finances undertaken. He hoped that whatever was done those who would have charge of the overhauling of the finances would not feel it necessary to reduce the salaries and appointments of the teaching staff. Their teaching staff, he urged, must be of the very best, and whatever else had to go towards the reduction of expenses he hoped they would always be able to keep the most proficient teachers for their students. They were interested to hear of the progress of the various branches of the Association, and of the success of the Register of Assistants. He was more or less responsible for the suggestion that the Association should keep the register for its own members, and he was glad to hear the rearrangement had borne fruit.

Sir Aston Webb, R.A., said he wished to associate himself with the congratulations which Mr. Cave had offered to the President. He entirely agreed that so long an experience with the work of the Association marked the President out as just the man to occupy the chair. The President was very well known to him, as he had had the honour and pleasure of having him in his office for some time, and he only left it to better himself and ultimately to practise independently. It was suggested in the address that some of the ancient presidents should look back and make comparisons between the Association of their time and the present. Sir Aston Webb said he could speak of thirty years ago, when he was honorary secretary, and he could say that they did better now than then. He was amazed at the number of prizes distributed that evening. In connection with the prizes, he congratulated his old friend, Mr. Flint Clarkson, on the phenomenal success of his son during the year. Another familiar name among the prize-winners was that of E. W. Mountford, another Fellowes Prynne. It was pleasant to find how many sons were succeeding to their fathers' practice, and it looked as if architecture was not such a bad thing as some would have them believe. They all lamented the decrease in the membership of the Association, and particularly so when that decrease was caused through death. In other ways he did not think a decrease was altogether to be regretted. The different schools throughout the country induced a number of men to enter the profession who would have little chance of success, and since there was a lack of employment it was well that the number of students should diminish. As to women architects, he was not at all in favour of them, nor was he in favour of registration, but the latter was a question of politics which he would not touch upon that evening. Referring to the schools of the Association, he said he had been greatly interested in them for many years. He remembered when Mr. Seth-Smith suggested that they should have a day school, and the astonishment when it was successfully started. He was not in a position to speak for the Royal Academy, but he could say that the Royal Academy was desirous of working with the Association in the matter of their schools, and everything that could be done to bring those schools into co-ordination would be welcomed. He had been through all the offices of the Association and the Institute and the Royal Academy, and he could see the relative position that each of those bodies should hold. The position of the Association was for the elementary education, that of the Royal Academy for the final finish, and the Royal Institute as the sister of both by the examinations and prizes offered. He thought there should be a closer connection between the Royal Academy schools and the Association, and towards that end some forward movement might be made by the Association. In alluding to the "At Homes" it was proposed to hold during the coming session, he reminded them the Associa-

Digitized by Google

tion was for young men, and he would be sorry if it became a second Institute; they had already imitated the senior body too much. Reference had been made in the address to steel-framed construction and the modern conditions of practice. The change was bound to come, and it was of the greatest importance, he said, that young men should face those facts and get in touch with the requirements as they arose.

Mr. W. H. Seth-Smith also alluded to modern scientific construction. In his opinion they would have to deal with the question in their schools, because far more science would have to be acquired by architects if they were to keep the work within their own professional ranks.

Mr. J. Osborne Smith supported the vote of thanks, which was passed by loud acclamation.

THE ASSOCIATION OF ENGINEERS-IN-CHARGE.*

(Concluded from last week.)

THOSE who have to carry out construction in brickwork know the difficulty that exists in bonding bricks of different quality, or from different sources, as although each group being made from the same size mould will not vary much, the different groups show considerable variation. A London brick averages 8⅞ inches by 4⅜ inches by 2⅝ inches, but a Midland or Northern brick will be approximately 9 inches by 4½ inches by 3 inches. The Royal Institute of British Architects, in consultation with the Brickmakers' Association and the Institution of Civil Engineers, framed conditions which came into force on May 1, 1904, fixing the average size of bricks and joints, which may be summed up as giving the standard size of the bricks as 9 inches by 4.375 inches by 2.6875 inches.

The use of co-ordinates in the production of curves is of extreme value in the case of any standard which consists of a series of values or dimensions. Numerals can only be grasped consecutively, but curves can be observed as a whole, and any irregularity is self-evident. So far back as 1860 I was using curves in this way, and have constantly adopted them for checking experiments and tests and tabulating proportions. The "uniformity of Nature" is a very definite fact, and there would be less irregularity in the records of tests if it were the general practice to plot them to curves.

Some years ago an elaborate series of experiments was made upon riveted joints, under the auspices of the Institution of Mechanical Engineers; but although I gave considerable time to their elucidation, I was not able to formulate them into any general standard for my own use. It is a subject that would well repay the trouble of casting into a popular form, so that given a material of standard quality one might know the best pitch and diameter of rivets for mere strength in girder and bridge work, and to resist fluid pressure in addition in boiler and tank work.

Eye-bars, or eyes for the ends of links, for bridges, roofs, cranes, &c., was another matter to which considerable attention was given some forty years ago, with the result that there were many suggested forms, but not one that could be called a general standard. We cannot say that mild steel represents finality in structural material, but it would be useful to have a standard form of eye-bar in this material.

Having been brought up as a mechanical engineer, I seem to drift generally to that aspect of any subject, but under the head of standardisation we have many branches to consider. I have only to mention the words "candle power" to call to your mind a standard that we have heard a very great deal about since the introduction of the electric light. The standard candle, or, as it is sometimes called, the British Parliamentary candle, is a sperm candle, six to the lb., ⅞ inch in diameter, and burning at the rate of 120 grains of spermaceti per hour. The "One-Candle Pentane Air-Gas Flame," invented by Dr. A. Vernon Harcourt, represents the true average value of the light of the legal standard sperm candle, but it is actually equivalent to 1.001 sperm candles. A similarly constructed ten-candle lamp was made permissible in 1898 for the official testing of London gas. The standard gas burner used for testing the illuminating power of all qualities of gas is the Sugg "London" (No. 1) argand burner, consuming gas at the rate of 5 cubic feet per hour, with a chimney 6 inches long and 1⅞ inches internal diameter. In France the standard illuminant is the Carcel lamp, burning 648 grains of pure oil per hour, and equal to about 7½ candles. The German (Hefner) standard candle-power is only 88 per cent. of the English standard; German lamps are, therefore, rated too high compared with English. The Hefner lamp was adopted in 1896 as the practical international unit measure of light.

Other countries besides our own have given much consideration to the question of a standard of light, and there are many difficulties still to be overcome: the latest information is from the Bureau of Standards in the United States. Mr. Nutting, of the Bureau, brings forward an entirely new standard in the light emitted by a body of glowing helium gas. Helium, it will be remembered, says the *Engineering Record*, is an extremely light gas which produces a well-known bright line in the yellow of the solar spectrum that puzzled the astronomers for many years. Found first terrestrially in mere spectroscopic traces in the gases occluded in certain specimens of lava, it was finally found in the rare mineral cleveite, isolated and examined, and has since been discovered to be an almost infinitesimal normal component of the atmosphere. One of its many peculiarities is that it glows when electrically excited at reduced pressure with an exceptionally bright yellowish-white colour, much nearer the hue of ordinary artificial illuminants than the colour given by any other permanent gas. It was next found that a capillary tube, say a couple of inches long and one-tenth of an inch in diameter, could readily be so excited as to give an extremely steady light of one or two candle-power per inch of length, and that the tubes could apparently be readily duplicated to give concordant results. Bringing the tube to standard condition means merely applying a definite and very easily measured electric current. The life of the helium tube is not yet determined, but there is reason to think that it can be made reasonably good, especially if it should prove feasible to make a capillary tube of quartz.

Here, then, one has a standard light which seems to be capable of ready reproduction, and which is of good colour and fairly satisfactory magnitude. With quartz tubes the available magnitude could probably be increased to 5 or 10 candle-power, which would be still better for the comparison of secondary standards. The light is entirely free from atmospheric conditions, and in steadiness leaves little to be desired. It is too early in the investigation to pass judgment on the true value of the helium tube as a standard; but it certainly looks very promising indeed, and is especially interesting on account of its novelty and simplicity.

The application of a standard of illuminating value to coal gas, although originated for that purpose, is felt to be somewhat of an anomaly, since incandescent mantles have been so widely adopted. It is the calorific value that is now the main consideration, and gas companies are consequently endeavouring to improve this by reducing the illuminating power. The South Metropolitan Gas Company, so far back as 1900, obtained permission to reduce their gas from 16 to 14 candle-power, and last year the Edinburgh and Leith Gas Commissioners reduced the candle-power of their gas from 20 to 14. It is probable that a combined test will ultimately be substituted as a standard for the present test of the candle-power of the naked flame.

James Watt, at the latter end of the eighteenth century, introduced the first standard for the rating of engines and machinery, viz., the horse-power of 33,000 foot-lbs. per minute. He knew that the actual power of a horse was about 22,000 foot-lbs. per minute, but he wanted his engines to be well ahead of their specification, so he allowed a 50 per cent. margin. The various kinds of horse-power that one hears about—indicated brake, nominal, actual, &c.—only refer to the mode of measuring or expressing it, and not to any intrinsic difference in the standard. Only two of them are really needed—the "indicated," which is the horse-power in the cylinder; and the "brake," which is the horse-power given out at the crank-shaft. In fact, it would be an advantage to use the term brake-horse-power alone as being the actual power the engine can give out. Nominal horse-power is a useless commercial term, which may mean anything, and should be entirely abolished. In passing I may say that James Watt missed a grand opportunity in not making the circular inch the standard upon which steam pressure should be measured.

Just now there seems to be some stir about the proper mode of standardising the power of small petrol motors. They cannot very well be "indicated," and various proposals have been made to establish a comparison by the dimensions. The Royal Automobile Club (1906) gave the rule for power rating as $\frac{2}{3} D^2 n$, where D is diameter of pistons in inches, and n the

number of cylinders. H. Sturmey gave a horse-power formula as follows: $\frac{D^2SNR}{12500}$ where D is diameter and S stroke, N number of cylinders, and R revolutions per minute, to be taken as 1,000 if the actual number is unknown. This formula is practically the same as the ordinary horse-power formula for steam engines, assuming a mean pressure of 42 lbs. per square inch throughout the stroke.

Explosives are so largely used in certain engineering work that the need of standarising them has been suggested, and a start has been made by the American Society for Testing Materials. For some 500 years gunpowder only was at the command of the engineer, but since 1845 many other materials have been invented or discovered and used for blasting purposes. It is calculated that over 1,000 different explosives have been offered for use, and as their precise composition and mode of using are of vital importance, it is fit and proper that they should conform to certain standards.

The standardisation of catalogues has been talked about for many years, but makes little progress. The Architects' Technical Bureau are issuing to their members special covers and uniform sheets illustrating building materials and sundries supplied by the various manufacturers, but these are too much in the manner of displayed pictorial advertisements to be of real value. The Engineers' Standardised Publications Association appear to be doing similar work for engineers. The handiest sizes for catalogues and circulars are 8 inches by 5 inches, 10 inches by 8 inches, and 13 inches by 8 inches, corresponding with note, letter, and foolscap sizes of writing papers, but printed papers generally run a trifle larger.

Standardisation is not confined to engineering matters; the Quantity Surveyors' Association have commenced to standardise the modes of measurement for builders' quantities, and have issued No. 1 of their "Uniformity of Measurement" pamphlets, which deals with the measurement of slating and roof-tiling work; previously Leaning's book, entitled "Quantity Surveying," was the nearest approach to a standard that was available. There is every advantage upon the score of uniformity of procedure in producing such works, but the publication of a good text-book in any subject tends to standardise the work in that subject, and to some extent to cramp the minds of the students by giving the impression of finality. Although there are undoubted advantages in standardisation, it chiefly helps the average man, and aids economical production; while the man of intellect is more or less hampered by having a rigid model set up for him beyond which he may not pass. The whole tendency of modern education and official regulation is to make one man as much like another as possible, to stamp out individuality and to discount common sense. I have had not a little to do with technical education, and in a small way have attempted to stem the tide of the current reliability on rules and formulae. I have always advised students to try to understand the principles, and then the formulae would follow of their own accord without being a burden to the memory. My remark to a student on one occasion shows what I mean. He was troubled about a formula for some simple thing, and in remonstrating I said, "If you were in a stokehold when a gauge glass burst, you would want a formula to help you out of danger."

Reference may be made here to the proposal of standard notation for algebraic formulae, which was taken up by the Civil and Mechanical Engineers' Society, and a discussion opened by the President, Mr. W. Noble Twelvetrees, on January 2, 1908. The same subject was considered by the International Commission on Reinforced Concrete at Bâle on October 12, 1908, and a resolution was proposed that "a uniform mathematical notation for the most important magnitudes occurring in the specifications and statical computations should be drawn up," and early in 1909 an interim report was issued, which was a distinct step in advance, but the result was somewhat crude. The Concrete Institute took up the matter at this stage, and after several meetings of the Science Standard Committee and Special Sub-Committee on Notation, of both of which I was a member, a draft report was prepared which is published in the Concrete Institute *Transactions*, Vol. I., Part III. Although all members of the sub-committee were assiduous in their labours, the chief credit must be given to Mr. E. Fiander Etchells, who was most enthusiastic. Briefly, the proposed notation is based upon what is called the "three-alphabet system," in which initial letters in "Latin smalls" are used for lineal dimensions, intensities of forces, loads and stresses, constants, &c.; in "Latin capitals" for areas and volumes, moments, total forces, loads and stresses, angles, constants, &c.; and in "Greek smalls" for angles, constants, &c. The reduction of half a dozen of the best-known but apparently dissimilar ferro-concrete formulae to the standard notation causes all their differences to disappear, and there is no doubt that much advantage would accrue from the general use of the same letters to represent the same things.

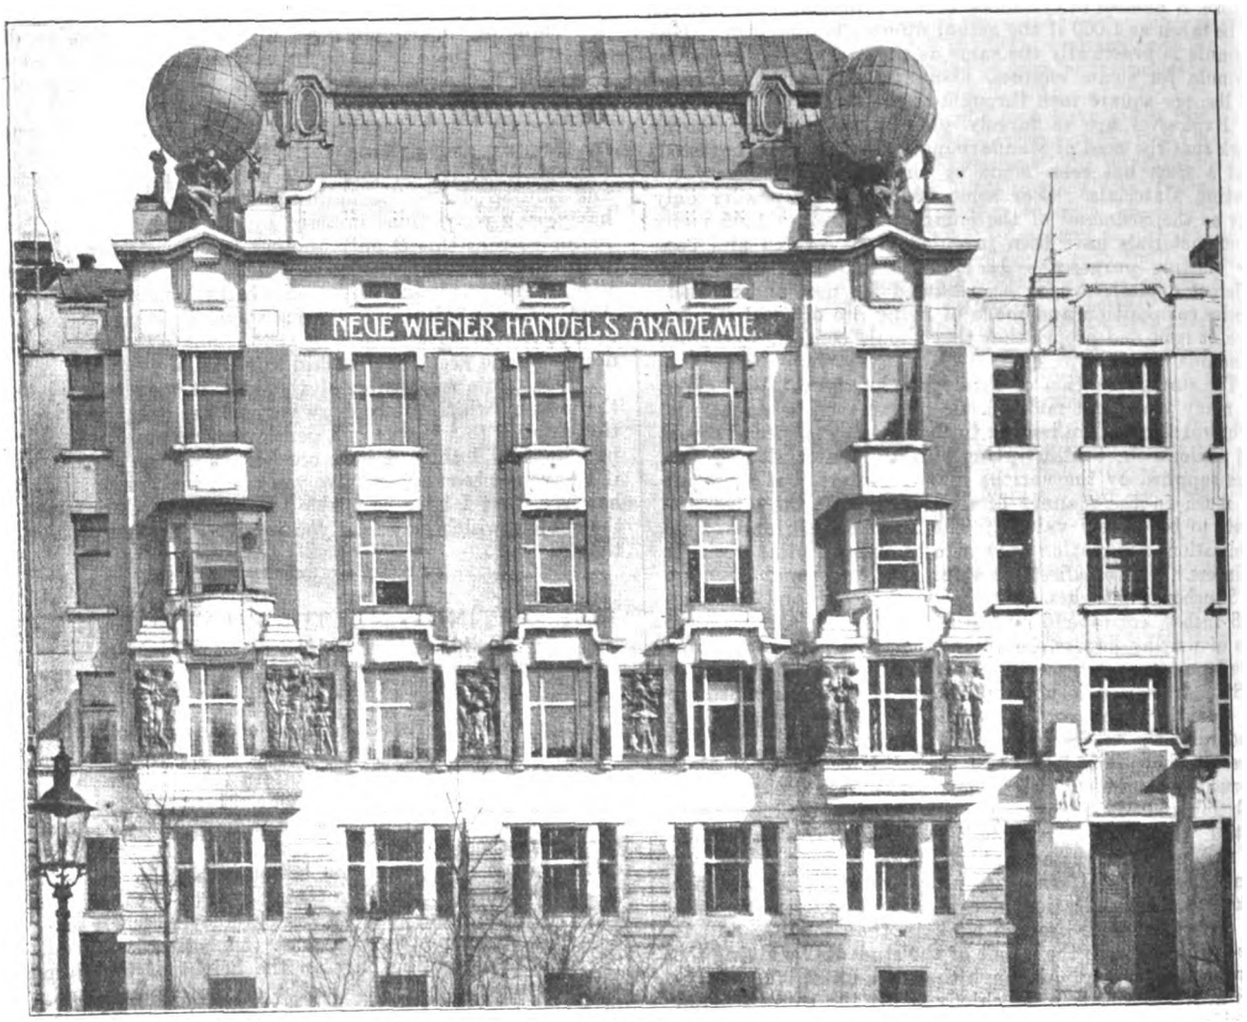
Recently I have been assisting the London County Council in framing and passing their Building Act amendments through Parliament, to permit of steel frame construction and reinforced concrete buildings being erected without the hampering restrictions imposed by the 1894 Act, and I am reminded that this is only another form of standardisation. If architecture and engineering had been close professions like law and medicine there would be little need for Building Acts, as only competent persons would be registered, while such Acts now have to be framed to regulate the incompetent designers and keep them within safe limits.

By a little expansion of the idea it may be said that the laws by which the country is ruled are only standardisation applied to actions; but, gentlemen, we must not get into politics, and I think I have occupied sufficient of your time if I have not been able to give you much instruction. I trust, however, that I have been able to arouse a little interest in the subject which may lead you to give it further consideration.

THE RATING AND TESTING OF BOILERS FOR HEATING INSTALLATIONS.*

(*Concluded from page* 237.)

Chimney.—The function of the chimney is to aspirate a sufficient but not excessive quantity of air through the incandescent fuel in order to maintain the combustion of the required quantity of fuel per hour. I have often thought that the use of the draught gauge is imperfectly understood by many of those engaged in this business. A hot flue which is freely open at the top and bottom will show no draught on a water gauge, although a strong current of air is passing up it. On the other hand, a hot chimney which is open at the top and completely closed at the bottom will show a "draught" depending only on the height of the chimney and its temperature. The height of the chimney and the difference of internal and external temperature produce what may be called the total "aeromotive force" of the chimney. This is the value of the suction—generally expressed in inches of water—which would be produced at the base of the chimney when there is no actual current of air passing up it, that is, when the bottom damper is completely closed, and when the temperature of the chimney is the same as in actual practice—generally about 500 deg. The aeromotive force depends only on the height and temperature difference, and not at all on the sectional area or resistance in the chimney. When a certain number of cubic feet of air per hour are passed up that chimney, the temperature being still maintained, the suction indicated on the gauge decreases, that is, a certain proportion of the total aeromotive force is dissipated by the friction of the air in the chimney, the amount depending on the sectional area or resistance of the chimney, and the more air there is allowed to pass, the more of the total aeromotive force is dissipated, until when the bottom damper is freely open, the dissipation of the aeromotive force is complete, and the chimney passes its maximum quantity of gas without forced draught, and the draught gauge shows no "suction" whatever.



When this chimney is drawing air through a boiler filled with incandescent fuel, some of the total aeromotive force is dissipated in the flues of the boiler itself by friction. When the quantity of air passing is sufficient to provide for the maximum power of the boiler, the difference between the water gauge suction below the firebars and that at the outlet of the boiler flues leading into the chimney on the boiler side of the damper, measures the resistance of the boiler, that is the amount of pressure necessary to force the maximum required quantity of air through the incandescent fuel and flues of the boiler. This resistance varies not only with the boiler design, but also with the kind of fuel used, the quantity on the furnace at one time, and the amount of dust and ashes which have accumulated on the grate bars, and other matters.

The total aeromotive force of the chimney must be such

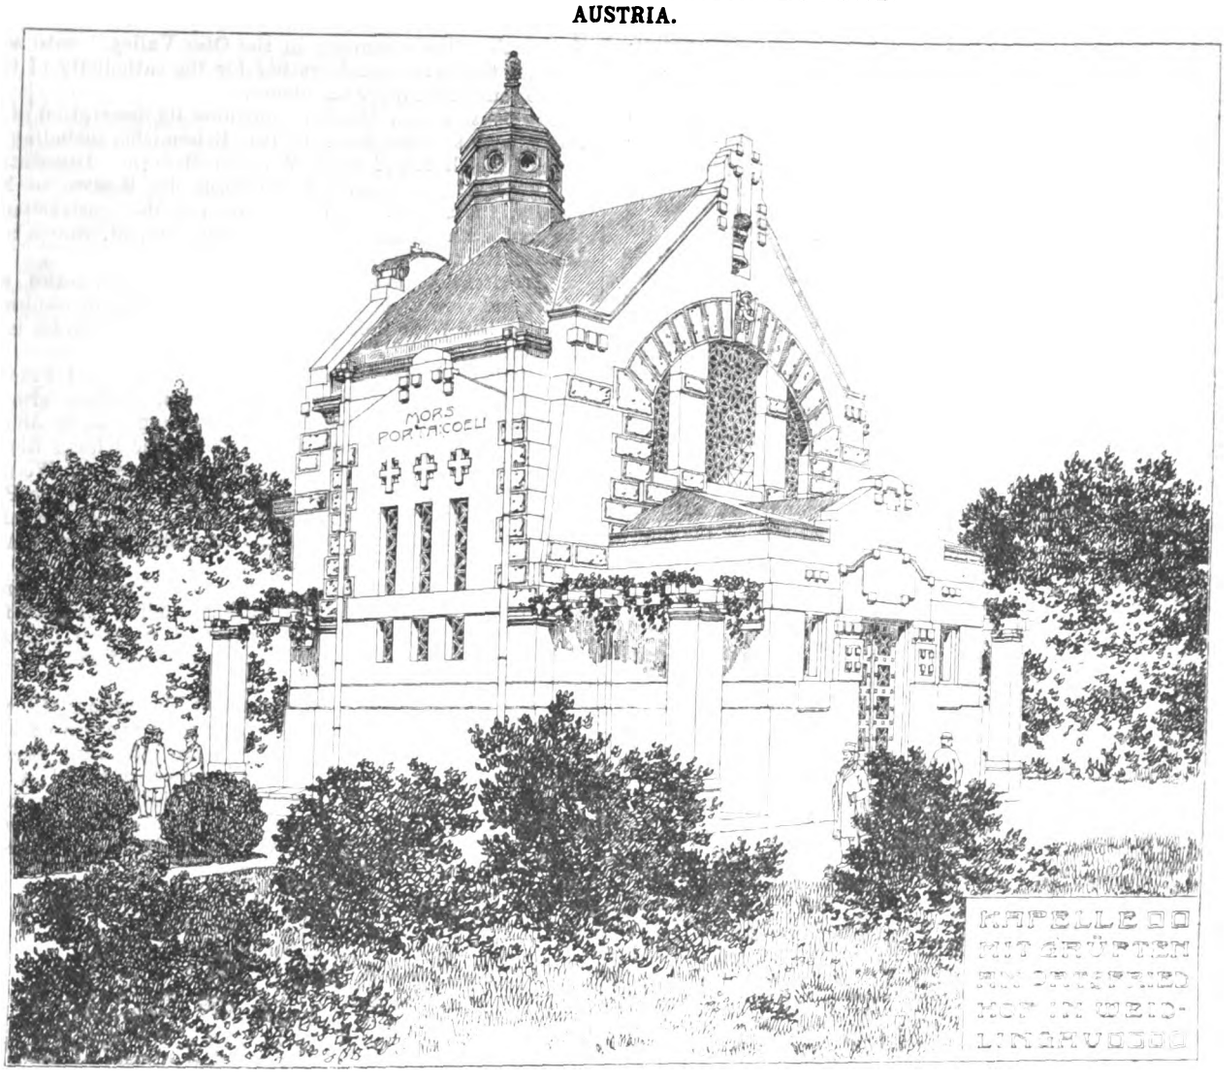
that at all times and in all circumstances it will be sufficient to provide not only for overcoming the resistance of the chimney itself, when passing such a quantity of products of combustion as will be given off from a grate consuming the required weight of fuel per hour, but will also provide a surplus of pressure to overcome the resistance of the boiler when fully charged with fuel for a long run, and when the grate bars have accumulated a moderate quantity of ashes.

This is the real criterion of adequacy of a chimney. Many engineers are satisfied with their inspection of a chimney if it "pulls," but the real question is, does it pull when it is passing the proper quantity of flue gases, and does it pull hard enough to draw that air through a dirty fire? If it does not, the caretaker will have to be continually cleaning the fire so as to keep the internal resistance of the boiler down, and if it pulls too hard, he will have to be continually adjusting the damper to prevent damage to the fire-grate when the fire is clean. This cannot be prevented by an automatic regulator. It is quite possible to burn firebars out when the water in the boiler is nearly cold.

If there is an excess of chimney power, it is imperative for safety to have an adjustable fixed damper, which can be set once for all so as to be not under control of the attendant. If this is not provided, a bad attendant may mean a destroyed fire-grate. In any event, care will have to be taken that there is never too great a variation in internal resistance of the boiler, otherwise a draught which would be insufficient when the fire is dirty might be enough to destroy the fire-grate when it was clean.

Different boilers vary very much in internal resistance when clean. There are boilers which require as much as $\frac{1}{8}$ inch to $\frac{1}{2}$ inch of pull to draw sufficient air through the furnace to maintain complete combustion. Other boilers do not require more than 1/32 inch. It is evident that a chimney which is quite adequate for the latter might be totally inadequate for the former, so that it is clear that no experimental comparison of two boilers can be made merely by substituting one for the other in the same situation.

But chimneys are generally recommended which are considerably in excess of actual requirements so that a high resistance boiler can generally be used with them. But it is clear that a low resistance boiler runs more danger of burning the fire-grate than does a high resistance one, because the difference in resistance due to a dirty fire bears a greater proportion to the total.



Area of Fire-Grate.—A great deal of what I venture to consider unnecessary attention has been devoted to the question of the area of the fire-grate. According to my view, this should be determined from many other considerations besides the power of the boiler. My own opinion is that what should determine the area of the fire-grate is, first, the number of pounds of fuel which can be burnt on it without damaging the bars; secondly, how long a charge of fuel is to be left on it without requiring the fire to be cleaned. If you can actually and completely burn on it all the fuel you require without damage and without requiring an inordinate amount of cleaning, the area of your grate matters not at all. If the firebars are water cooled, and the draught is adequate, it is easy to get an enormously high rate of combustion per square foot of fire-grate without detriment, unless the quality of fuel used is such as to choke up the bars, and thereby increase too much the internal resistance of the boiler.

Quantity of Fuel Burnt.—One of the main things to be determined in finding the power of the boiler irrespective of economy in fuel, is the amount of fuel which can be burnt in the fire-grate without damaging the fire bars. The maximum power of a boiler depends on the maximum quantity of fuel which can be burnt in the grate. To fix our ideas, let us take a boiler which would be fairly rated at 1,000 square

MAUSOLEUM AT WEIDLINGAU. [From *Der Architekt.*
MAX HEGELE, Architect.

feet of surface; such a boiler would probably have from 40 to 50 square feet of heating surface. Now suppose there is unlimited draught at command, and that it can be arranged to burn as much or as little fuel on the furnace as required. Suppose five pounds per hour are burnt in such a boiler. This liberates say 65,000 B.T.U., of which one might reasonably expect to transfer to the water, say 60 per cent. or 40,000 B.T.U. per hour. Such a fire would maintain in the radiators a temperature of say about 90 deg. F.

By adjusting and increasing the draught, you might arrange to burn successively say 10 lb., 15 lb., 20 lb., 25 lb., 30 lb. per hour, and so on until you arrive at such a point that the intense heat of combustion damages the fire-grate, or perhaps the internal resistance of the boiler to passage of air would be such that without having a great and utterly impracticable draught, it would be impossible to get sufficient air through the boiler to burn any more fuel. Whenever any of these conditions become such as to be impracticable in ordinary use, it is an indication that the boiler is unequal to burning that quantity of fuel per hour, and you have thereby fixed a limit of power of the boiler which it is impossible to exceed. But so long as you can increase the temperature of the products of combustion in a boiler by burning more and more fuel, so long is it possible to increase the number of B.T.U. which can be transferred to the boiler water. The difficulty of determining the exact maximum point is obvious, indeed it cannot be determined to within 25 or 50 per cent. But even if it were determined we should be as far as ever from a determination of the practical limit. In order to determine the latter, we must enquire into the requirements of the customer or user of the boiler. If a furnace is burning at its maximum rate, everybody knows that in practice the fire will soon either clinker or choke up or burn through, or something will happen to diminish the effect; that is, in order to maintain this rate of combustion the attendant must be continually tinkering with the fire. If he does not the heat will go down. It appears necessary, therefore, to fix a time during which the fire must maintain the heat of the boiler without being attended to. During the earlier part of this period the temperature will be greater, and during the latter part it will be less. A very perfect automatic regulator, combined with a very powerful available draught, might maintain the temperature almost constant in practice, but if it did, the boiler during the earlier part of the time would be working much below its maximum capacity. The shorter the time fixed, the higher will be the power of the boiler, and *vice versa*, so that in specifying the power of a boiler for practical use one must fix the time during which the boiler is to be left unattended, otherwise the expression "maximum power" has no meaning. This is, of course, intimately connected with the fuel capacity of the firebox, but not solely. Some boilers can be filled up with fuel, and, if left unattended for some hours, the fire will burn down and grow cold, even though there is a good deal of unconsumed fuel in the furnace. In order to restore the temperature, the fire has to be cleaned. This is more so with some fuels than with others, so that it seems to me to be impossible to specify the exact power of the boiler without reference to the kind of fuel used.

Economy.—The question of economy is quite a separate matter. Generally speaking, as the consumption goes up, the economy goes down. The less fuel burnt per hour above a certain limit, the greater the proportion of the total heat generated is transferred to the water. The existence of a lower limit is due to the fact that if you are burning so little fuel that in order to burn it at all you must have an excess of air, the temperature of the products of combustion is reduced after leaving the incandescent fuel, and the economy goes down. It follows then that for every boiler there is a

Digitized by Google

point of maximum efficiency, in other words a point where the fuel is most efficiently utilised. Now, in my view, no test of a boiler is of much scientific, nor even of much practical value, unless it takes into account both these matters.

One must know what is the effect of a prolonged run at different rates of combustion, and one must also know which is the point of maximum economy, and the relation between the economy at the maximum and at other rates.
